The last *Review* at hand contains the conclusion of Experimenter Taylor's experiments in wintering. Among other things his object was to determine whether moisture in excess had anything to do in causing dysentery. The results seem to show that it does not. Mr. T. seems inclined to believe that the disease is due rather to the food, and to the fact that the temperature is such that the bees are not able while in the cellar to pass out of the hive and void their feces. As between upward ventilation and sealed covers in the cellar, there is practically no difference in results. The temperature of the cellar where these experiments were tried was practically uniform, varying only from 43 to 45°.

THIN VENEER FOUNDATION.

A NEW firm, Schmidt & Thiele, New London, Wis., send us a sample of veneer foundation, and request our opinion on the same, in GLEANINGS. It is simply a thin sheet of wood, $\frac{1}{16}$ of an inch or less, covered with cell-walls of ordinary foundation. The object is to give truer combs, and combs that will not sag. We learn that Schmidt & Thiele are going to get out a patent on it. I do not like to discourage a worthy invention, but it will surely be a waste of money for them to invest in a patent to cover this idea, when it is already sixteen years old and over. Sixteen years ago, after having tried paper, cloth, and the like, as a background, with indifferent success, A. I. Root tried the wood; and this is the way he threw up his hat:

I have succeeded perfectly, with a board about $\frac{1}{8}$ inch in thickness; and the only difficulty now consists in getting these boards coated perfectly with wax, on which to make the foundation. For once in the world, we have combs perfectly even, and safe from sagging. You can scrape off the honey if you like, and let the bees build on more; but the boys complain that they can not cut out queen-cells from them.

That was published away back in August, 1879, on page 317 of GLEANINGS. Later on, a more elaborate description was given in our

A B C book; but, like a great many things that promised a great revolution, it died a natural death. In the first place, such foundation can not be made to compete in price with ordinary foundation; and while it prevented the sagging of cells, and made the most beautiful combs, bees would at times gnaw the wax off, leaving the thin veneer of wood; and at other times the veneer has a disagreeable habit of warping, pulling the combs out of true. But I presume that bee-keepers could have got along with this had it not been for the increased expense. While Schmidt & Thiele offer this at less per pound than ordinary foundation, it weighs proportionally a good deal more per square inch; and, after all, the present methods of wiring seem to do away with the disagreeable sagging, and at the same time stiffen the combs fully as much as the wood.

I very much dislike to throw cold water on Schmidt & Thiele's veneer foundation; but at the same time I believe I am doing them a *greater kindness* in showing them what has been done, and that a patent, even if secured, would be valueless in the face of printed matter like the above.

FOUL BROOD IN ENGLAND.

We have just received a copy of the Report of the Committee on the Bee-keeping Industry and Foul Brood in the United Kingdom. It sets forth in a very thorough manner the possibilities in the line of apiculture in the British Isles were it not for the shadow flung on it all by foul brood (which seems to have its own way so far as the law is concerned), before which disease English bee-keepers seem to be powerless. The British Bee-keepers' Association is now trying to have apiculture recognized as an industry, and to have suitable legislation enacted to drive the fell disease from their shores. Our British brethren seem to be hampered in this direction more than we are here, and are more inclined to say, "What can't be cured must be endured." The American version in that case would be, "What can't be endured must be cured," and Canada has about done so. The mother-country is much behind Canada in this respect, where foul brood at present is likely to find its match.

The report was compiled under the supervision of Thos. Wm. Cowan, editor of the *British Bee Journal*, who gives us the following information:

The annual value of bee-keeping in England and Wales would probably reach \$750,000, aside from sale of bees. The annual yield of honey and wax in the same place approaches 4,000,000 lbs. More honey could be gathered if more bees were kept; not enough bees are kept; demand for honey increases with the supply; area of pasture land is increasing. Prosecutions for the sale of adulterated wax have improved the demand for pure wax. The use of

native honey is encouraged as a preference over foreign. The value of the bee as a fertilizer is beginning to be understood. In this respect the value of the bee is greater than the value of the honey and wax. Twenty times more bees than other insects visit the bloom which is absolutely dependent on insects for pollination. In England and Wales there are 20 bee-keepers' associations, with 4104 members; number of hives, 260,000; average per hive, 17 lbs.; wax per hive, 4 ounces. Ireland produced 248,363 lbs. of honey and 3188 lbs. of wax, which is considered an underestimate. It is believed that Scotland exceeds this, but statistics can not be obtained.

A STUDY OF INSECTS.

A SCIENTIFIC treatise on this subject, and yet one adapted to the capacity of the average reader, is what the book named above purports to be. It has 700 pages, the size of this one. It is illustrated with 797 cuts, all engraved for this work by Anna B. Comstock, its assistant editor. These cuts were all made from the creature itself, and certainly leave nothing to be desired, and they are a monument to the skill of a woman's hand. Twenty-two orders of insects are described fully, while the total number is almost beyond count. All of the old bugs peculiar to this country (except hum—) are here seen, drawn with remarkable fidelity, especially the "tree-hoppers," which are certainly funny enough to suggest to the author the idea that Nature must have been in a joking mood when she created them. We can not think of an enemy of any of our garden and field crops which is not here described, with information as to their destruction. The subject of "Beemoths" will be found to be very interesting to bee-keepers, as will also the bee itself, although the latter has had such special treatment by Cheshire, Cook, Cowan, and others as to leave this book in question entirely in the shade, as a matter of course. But it takes us into a world of wonders, and most of these "wonders" are at present the enemies if not the scourges of the agriculturist if not, indeed, of the human race. We know of no book which will better enable us to combat such foes; and to be forewarned is to be forearmed. The scientific names are so printed as to enable any one to pronounce them at sight. As to the author, his name is John Henry Comstock, Professor of Entomology in Cornell University and in the Leland Stanford Junior University; and after that is said, nothing more needs to be remarked in regard to the thorough manner in which the work has been done. The price is \$3.75; postage 34 cts. extra. Printed and published by the Comstock Publishing Co., Ithaca, N. Y., to whom all orders should be addressed.

The work has been adopted in twenty-six colleges as a text-book, and twenty of these are agricultural.

W. P. R.

HANDLING HIVES; THE METHODS OF DIAGNOSING WITHOUT HANDLING FRAMES, ETC.

I MAKE it a part of my business, assisted by a light-weight safety bicycle, to take entire charge of our out-yard. This I have done for the last three or four seasons. While I keep track pretty closely of our home yard, I do not do much work with it except to hive an occasional swarm on Sundays and other days when our regular man is not about. Early this spring, as soon as the roads were fit, I took a run down to our basswood apiary, peered under all the cushions, raised the sealed covers, and made an examination of each colony. I found that they had all wintered, whether under sealed covers or under absorbents, and that notwithstanding they were in a comparatively open field, with the exception of what protection the small basswood-trees afforded.

Again I went down a few days ago, and this time I gave them a very thorough examination. I took along a Crane smoker, a twenty-penny wire nail, and a silk-tulle veil. My object was to determine the amount of brood in each colony, the amount of stores, bees, etc. Now, I can not with my other work in the office afford to handle over every frame. After opening up the hive, with the wire nail I have just spoken of I removed the division-board, then ran the nail between the center pair of brood-frames, and pried them apart. This split the brood-nest perpendicularly in two equal parts, leaving a space of from $\frac{1}{2}$ to $\frac{3}{4}$ inch between them. In some cases I lifted out one frame, and in others I got satisfactory information by simply peering in between the frames. In the latter case, if not entirely satisfied as to the amount of stores I split the brood-nest in another part, and peered down between the frames as before. This usually gave me an idea of the amount of stores. After having satisfied myself as to the condition of the colony, I pried on the outside frame, crowded the whole set of frames together *en masse*, inserted the division-board, and closed the hive up. If there was any thing unusual, or something requiring attention, I laid a brick, or block of wood, on top of the hive.

If, in splitting the brood-nest perpendicularly in two equal parts, and looking down between the frames, I thought the brood looked a little irregular, or scanty in amount, I pulled out a frame to see whether there were eggs. If these were present, and the brood well capped over, and healthy-looking, I replaced the frame, crowded over the other four with one operation, and closed up the hive. I seldom if ever stop to hunt for the queen. If I see eggs I know that she is present in the hive, or at least she has been within a very short time. Eggs are supposed to be eggs for at least three days. But, supposing the queen was killed the day before I examined, I think I should be able to recognize her absence, even if I saw eggs, by

the howl of distress on the part of the bees. Old bee-keepers know what this "howl" or uneasy humming means. It does not *always* indicate queenlessness, it is true; but, with other conditions easily ascertained, it is not difficult to tell whether the hive is queenless, without even hardly handling a frame.

How the divisible brood-chamber can be handled any more rapidly than a good hive containing modern Hoffman frames with V edges, is past my comprehension. I have handled the former somewhat in our own apiary. That is to say, we have had a Heddon hive in our yard for a number of seasons; and I have manipulated that hive perhaps more than any other one hive in our yard. We have also had a Danzenbaker hive in our yard for a part of one season. I have seen divisible-brood-chamber hives handled by bee-keepers who were very enthusiastic over them; but, taking it all in all, I think I can get a more satisfactory knowledge with a given number of hives containing full-depth Hoffman frames in less time than from any equal number of horizontally divided brood-chamber hives I have ever seen or read of. I say I *think*. A positive assertion right here—and I refrain from making such a one—is but little short of rank egotism. Individual tastes, ways, and habits of working, will lead to a variety of opinions.

Mr. Heddon and Mr. Danzenbaker, of course, will both think their ways are better, and they certainly have a right to their opinions. Now, why do I like mine (or, more correctly, Hoffman's) better? A Hoffman-frame hive can be split *perpendicularly* in two parts. A divisible-brood-chamber can be split horizontally in two parts; but it will be apparent that such a split does not show brood *surface*—only the *edges* of the combs, and those very imperfectly. A *perpendicular* split does show the *whole surface* of two combs. Then if we remove one comb we have for examination the two surfaces of the one comb besides two surfaces of each of two other combs.

Although I have studied and experimented a good deal, I have never been able to diagnose accurately a colony merely by looking at the top and bottom edges of the combs; but if, for instance, I can see just one frame from the center of the brood-nest, or can see the two surfaces of two combs when a brood-nest is split as I have explained, I can judge—and so can every experienced bee-keeper—pretty accurately the amount of brood in those combs. To test myself, I have repeatedly, after forming an opinion, examined every frame, and I do not know that I have at any time found that I was mistaken in my first impression. Now, then, if it is a fact that the Hoffman-frame hive can be diagnosed as quickly—and I think more satisfactorily than by dividing the brood-nest the other way, horizontally—do we not, by having full-sized frames, gain some advantages? Bees,

according to my experience here, breed better in full-sized frames than in half-frames; and this experience of mine has been corroborated from what observations I could make, where horizontally divided brood-chambers were in use.

Last fall—or, rather, late last summer—we tried one Danzenbaker hive. I know one swallow does not make a summer; but in spite of all we could do, we could not get the bees by any kind of feeding to breed satisfactorily in the two chambers at once. The queen seemed determined to stay in one hive-section at a time; indeed, she would fill out the frames of one section full of brood; but go below or above she just wouldn't. The bees would put in pollen and honey, but there it stopped.

But with the Heddon hive we obtained very much more satisfactory results. Why? The Danzenbaker brood-frame uses thick and wide top-bars and bottom-bars, $1\frac{1}{8}$ wide by $\frac{3}{8}$ thick; but I have found that, between two sections of the Heddon, burr-combs will be built, and this to a great extent completes the two sets of brood-frames. But even this slight obstruction seemed to hinder somewhat the normal circles of brood, when compared with brood-frames solid without any obstructions between. I am, therefore, of the opinion that it would not do to have thick and wide top-bars for sectional brood-chambers; and that, if we are to have anything of that sort, Mr. Heddon's decision for narrow and thin top and bottom bars is about right. But he has burr-combs, and these I won't have—even if a part of the nuisance is obviated by a slat honey-board. Mr. Danzenbaker, in the attempt to obviate these, has possibly run into a snag more serious yet in the use of wide bars.

About this time I imagine I hear Doolittle chuckling, and saying, "There, didn't I tell you bees don't like to go past thick and wide top-bars?" Now, I am not taking any back track yet on this question. While I fear heavy bars between parts of the brood-chamber will not be satisfactory, I know they do not form any obstruction between brood-chamber proper and surplus—certainly far less obstruction than the old-style hive with thin top-bars, burr-combs, and slatted honey-boards; or, worse yet, burr-combs and no honey-boards, said burr-combs stuck fast to the bottom of the surplus.

I have endeavored to give you my honest impressions of what I believe to be true regarding these matters; but I was not quite willing to give expression to them just yet, because I desired to experiment and observe further along these lines. But now that the divisible-brood-chamber hive is being discussed, I think it is well that we look on the side that I have presented. I do not claim to be infallible in my opinions; and if I should change my mind it will be because truth, and an honest purpose to get out of ruts, will force me to do so.

Who then is that faithful and wise steward, whom his lord shall make ruler over his household?—LUKE 12:42.

In order to take the above little text in the sense I wish, let us first commence by supposing ourselves all to be servants to somebody, or servants to the great wide world, as you choose. In a measure I am *your* servant, dear friends, for you expect certain things of me. You have a right to expect them; and if I do not render these services to you faithfully, you have a right to complain. Come to think of it, I rather *like* to get letters taking me to task right in this line. Once in a while somebody says, "Look here, old friend; does this sound just like A. I. Root, or what we might expect of him?" Then follows an extract from some letter I have written when I may not have been exactly in the right frame of mind. Well, if we all recognize, then, that we are all *servants*, I am ready for my little talk to-day.

It is the first day of May, and, as usual, there is a general activity everywhere. Nobody is looking for a job; but a great many, on the contrary, are inquiring where they can get a man or boy to plant potatoes or make garden. Why, everybody is so busy here in Medina that Mrs. Root was telling me of a widow lady who got her garden spaded up and planted by a woman over *seventy years old*. She did it tip-top too. Of course, you know I rejoice in seeing everybody have something to do. Yesterday I met a man from the great oil regions of Findlay, O. He said that, since the recent advances in oil, new wells were being drilled, old ones were starting up, and the manufacturers of drilling-appliances were working day and night with all the help they could scrape up. During the past week we should have been running day and night, could efficient help have been obtained. As it was, we asked those who could bear the strain to put in twelve hours a day until we could get a little ahead of orders. Well, at such a time there is more than ever a demand for not only skilled laborers, but for those capable of taking charge of the unskilled, to see that they do their work right, and that mischief is not done. Above all things, we want *reliable* men. Of course, we can not demand that every man, woman, and child, be at their post invariably; but we do like to have notice, so that provision may be made for absences when it is *necessary* for hands to be away. But a great many people do not seem to have any conscience in vacating their posts.

The most serious annoyance comes where somebody stays away without a word of explanation. Perhaps he runs machinery. Three large boilers are now furnishing steam to do the work. Our big engine is crowded to its utmost capacity, and we have so many men in readiness to fill up any vacancy, and keep every thing moving, that, when they happen to be all well and on hand, it is sometimes a puzzle to find a place for them. Where a man is not running machinery, his absence without any notice throws things out of shape, and hinders those who are depending on him; but it is not quite like having a machine standing idle when somebody away off is urging us by letters and by telegram to hurry up the stuff which that machine is to make. Some people have a reputation for reliability. Oh how I do like that word *reliability*! It speaks of faith and

of hope; and I do not know but it speaks of charity too. What a comfort it is to have reliable people around you! A few days ago Mrs. Root paid me a compliment. Isn't that a strange thing to write about? What do you think it was? Why, she had been talking with somebody who had the blues, and would have it that every thing was "going to the dogs." I came in just afterward, and she said something like this:

"You do not know, dear husband, how thankful I am that you never get the blues. You are always hopeful, always full of life and energy."

Of course, she did not mean to say that I never get tired out. Well, I told her this morning that I wanted to pay her a compliment. The compliment was, that my wife had always been *reliable*. She never failed in any thing since I knew her, when it was a possible thing, not only in keeping her promises, but in coming up to what was expected of her. I do not believe I *ever* knew her to shirk, or play truant. And now if you will excuse me, that is enough of "my home" for the present.

Some years ago a young man worked for me who was a pretty good sort of fellow, but nothing remarkable that I know of in the way of reliability. When our neighbor across the way was short of an engineer, and asked if he could have John for a few days, I let the latter go; and as we were not rushed much at the time, John kept on in his new place. Years passed, and we had a revival in our town. John was one of the brightest new converts. His conversion extended clear to his fingers' ends—yes, and toes' too, I might say. Once or twice it seemed necessary, where he worked, to have some repairing done on their engine on Sunday, so as not to hinder work during the week. John objected. By and by things came around to where it seemed very desirable that we should get John back again, if his present employer could spare him. I went over and talked with my neighbor about it. He did not want to let John go. I was not much surprised; but during the conversation he made a remark something like this:

"The fact is, John is mighty reliable."

I could not help smiling. What an expression—"mighty reliable"! That is pretty strong language, friends, and it paid our friend John a very high compliment. My friend did not say so, but it seemed to be summed up something like this: "John has some peculiar notions, and it is sometimes quite inconvenient to have him refuse to help us when it is very desirable that a little bit of work should be done on Sunday; but notwithstanding all this, John is *mighty reliable*." Mind you, my neighbor did not say just the above, but I have sort o' paraphrased it so as to express about what I have reason to *suppose* he thought.

Now, my dear friend, has anybody ever said of you that *you* were "mighty reliable"? Why, that very fact gave John from fifty cents to a dollar a day extra, year in and year out. He is not as good a mechanic as some other men who do not get the pay he does. He always does his best, however, and he is a *growing* young man. In fact, he could not well be otherwise. Do some of you want to know whether his becoming a Christian made him more reliable? Why, to be sure it did. It would be a funny sort of Christianity that did *not* make a man more reliable. If instead of becoming a *Christian* he had become only a *hypocrite*, then of course it would make him *less* reliable. A great deal has been said about hypocrites; but, to tell the truth, I have never found many of them in the churches. The atmosphere is not congenial.

Let me tell you another story about reliability—

ty. A young man applied to us for work during our dull season. Finally one of my good friends in the teachers' meeting—a woman who has busied herself all her life in looking after the unfortunate—put in a strong plea for this young man. She said he had recently married. She knew that would please me, for I am always glad to hear about good young men and women getting married. Then she said she was pretty sure he either had been or was thinking of taking a start in life as a Christian. When business started up I sent for him, feeling glad I could give him a chance. He did exceedingly well; and every one with whom he worked admired his manliness and energy, and he was soon promoted. In our business councils his name was mentioned, and we had much hope that he would be able to fill some important post with good pay. Before he had been in his new place two weeks, however, a conversation something like the following came up. The foreman of the packing-room, who loads a car almost every day, besides filling no end of small orders, has perhaps a dozen good reliable men immediately under his charge. Well, he said:

"Mr. Root, do you know what has become of —?"

"Why, isn't he at work?"

"No, he has not shown up since last Thursday."

This was on Monday.

"Did he not tell you he wanted to be away, or has he not sent any explanation of his absence?"

"Not a word, and I need him the worst kind."

I immediately went to the time-clerk. She said he had said nothing to her about being away, but came around Saturday night and drew his pay, and walked off. He said nothing about being absent Monday—not a word as to whether he would or would not be back to work. I hunted up his brother, and he expressed surprise. He said he was pretty sure his brother was not sick, and did not know why he should be off. Monday afternoon as I was rushing past I caught a glimpse of somebody, but he did not look up enough so I could be sure who it was. I turned around after I had got past quite a little way, and sure enough it was —. Some time afterward I passed Jacob. By the way, Jacob is now the foreman of our packing-room. Some of our older readers will remember the Jacob at that mission Sunday-school, who used to be so prompt and reliable in having a text every Sunday, rain or shine, and Jacob used to repeat his text so clearly and plainly that everybody in the old schoolhouse heard every word of it. By the way, I wonder if I dare stop long enough to meddle with the affairs of one other "home" to just whisper in your ear. Now, don't tell anybody. Up at Jacob's house they have an *eight-pound boy*. He came to their home last night, the last day of April. I declare! since I have told so much I must tell you that the boy's mother used to be *queen-clerk* in the office.* Now let us go on with the story.

On the day in question, as I passed Jacob I stopped and remarked:

"Oh! I see — has come back to work. What reason did he give for skipping out without saying a word when we were so badly rushed?"

* May be some of you would like to inquire whether Jacob was on hand to look after his gang of men the day he first became father. Yes, sir, he was on hand as usual that day and the day after. He got up very early in the morning about that time, and did considerable rushing about; but he knew the situation of affairs, and stuck to his post right through every working hour.

"Why, he did not say any thing until I overhauled him a little, and then he explained that he stayed out to plant his potatoes; and after the potatoes were planted he went *visiting* a day or two.

Now, may be I have not stated the whole matter as it should be; but in any case I think it illustrates my meaning. I do not know what the custom is in other shops and factories. In fact, I have been feeling for a few days as if I should like to know. Do men who occupy important positions of trust and responsibility stay away to plant potatoes, or to make garden, without saying a word to the foreman of the room, to the time-clerk, or to the man who employs them? If that is the way to do, here in this land of "liberty," I will try to put up with it and not scold. But, dear friends, did you ever consider that this fashion of going through life cuts a terrible slice out of your daily wages—just one operation like the one I have mentioned above? I am very sorry indeed to hurt my young friend's feelings, but in the very nature of things such a proceeding may cost any young man hundreds of dollars before he gets through with it. Every little while somebody is sick. When it comes to the women-folks, somebody gets married (as the queen-clerk did), or vacancies occur. Then the question arises in our cabinet, "Who shall fill the place?" Many names are suggested: but almost the first thing that comes up is, "Is he *reliable*? Will he be on hand when wanted?" You see, with our methods of management, a missing hand, without previous arrangement, is like a link being lost in a big chain. A telegram comes in regard to an order that is being filled. The clerk who is away sometimes has charge of the order or other papers, and nobody else can find them. A man decides to put in some special crop. He sends a telegram, and wants his order changed. It may be possible to change it before the goods are off, if we could get charge of the matter. If the clerk who is needed is gone, other clerks tumble business papers over, may be throw them out of shape, and so lay the foundation for *other* mistakes, and perhaps even then fail to get hold of the thing needed until the train is gone. We have had men stay away with the *keys of the warehouse* in their pockets. I you should see your old friend A. I. Root at such a time as this you might know something of him then that you never knew before, or would not have known otherwise.

Just a word about going visiting. It is a good thing to cultivate sociable relations, I know; but it seems to me that April and May are two months in the year when but little visiting should be done. It is well enough for old men, and those out of health, to go visiting; but even then they should be careful about wasting the time of busy men.

It is a grand thing to have a garden; yes, I like to see every man have his own or even a rented home have a little patch of potatoes. But a man may be unwise about potatoes as well as other things. I would have the potatoes myself; but I do not think I would desert my post in the month of May to get them in. If working-hours were so long as not to afford time, I would plant them by moonlight, or, better still, between daylight and time of work in the morning. I think I would manage to do my visiting during dull seasons, if it could not be done evenings and mornings. There are almost always lulls in business. If a man comes to me and says, "Mr. Root, if it should come handy to spare me three or four days, or a week, without hindering business now, before a great while, it would be quite a favor," and such a request is made a week ahead of the time, or may be a little more, we can almost al-

ways bring things around so as to spare the one who wants to be absent; and if he does not want *too many* vacations, it does not spoil the man's usefulness and money value. A good many times when we have had more help than we really needed, I have asked several (one after the other) if they had any work of their own they wanted to do, or if they would not just as soon go visiting for a week, or something of the kind. By the time I have spoken thus to half a dozen men, I am sure to find one who wants just such a favor. Some of you may ask, "Mr. Root, if you object to anybody taking a day or more without previous arrangement, do you on the other hand always expect to provide work all sorts of weather for those in your employ?"

To which I reply, "Yes, sir, I do." It is something almost unheard of for a man to come to his place in the morning, and be told that there is no work, unless a breakdown happens, or that we are obliged to shut down for repairs. In order to do this we sometimes set a man worth \$1.50 a day on something that a boy worth 50 cts. can do almost as well. We do this for a short time rather than annoy him by asking him to lay off. While I was absent in the winter, I believe some of the hands were stopped temporarily on account of the weather. Had I been home, however, I could have set even these people at work. "As ye would that men should do unto you, do ye even so unto them."

I have sometimes felt like asking the question, "Well, my friend, for whom are you working, anyhow?" If somebody comes to you begging for work, and you give him a job, is there not a general understanding that he works for you alone until that job is finished? Come to think of it, I do remember one man who was away from his post so much that we began to inquire into it, and finally found out that he took jobs here and there, whenever he could get 25 cts. a day more than we were paying him. Of course, it is every man's privilege to do so if he thinks best. But does that kind of work pay? Surely not in the end, for people often come to me offering to work at *very low* wages providing I will give them a steady job the year round, they evidently having discovered by experience that steady employment every day, right along, is much better in the end than a day's work here and there, even at a higher price.

It just now occurs to me that my talk to-day may sound like fault-finding. I do not mean it to be so. Only a few feet from where I sit dictating is a woman who has been in my employ something over 26 years. A little further off is a man who is nearly forty, who has been in my employ steadily since he was a boy in his teens. Our stenographer remarks here that our boss printer has done better still, having been here for 26 years, or ever since he was in his teens; and he himself, who is writing down these notes, is just now finishing up 16 years here. When he commenced we talked perhaps 15 or 20 minutes about the matter of wages and work. In all these years he has had a job every day if he has wanted it, and his pay has been forthcoming every week, without an exception. I have learned to regard these old and tried friends with almost as much faith in their being at their post as I do the rising of the sun; and I presume they in a like manner have faith not only in my good will, but in my ability to guide our little ship (business ship) safely through the financial breakers. I need hardly say these friends have good pay. These pleasant relations were all built up by an energetic *reliability*, if that is the way to express it.

Now, I have been moved to throw out these hints as suggestions, especially to the younger people—the boys who have just *got married*, for instance. Sometimes the consequence of one man leaving his post for only a single day, without notice, in a large factory, is disastrous, not only in loss of money, but I think it sometimes brings about loss of life. A few days ago my attention was called to a pile of lumber that was put up so badly that high-priced choice boards were almost ruined. The boss of the lumber-yard explained it this way: He commenced the pile, and carried it up three or four feet; but as it was haying time, somebody wanted him badly to help get in hay. He was permitted to go, and another man was hastily and perhaps thoughtlessly directed to go on piling the lumber. The first one had been educated in his work, and knew just what to do and how to do it. The one who took his place had had little or no experience in that kind of work. There was a clear sharp line where the good lumber ended and where the damaged commenced. Once in a while we find a man who says:

"I should like to be away this afternoon, but I have arranged to have my work done by somebody who will do it right. If any thing comes amiss because it is *not* done right, just charge it up to me and I will pay the damage."

Now, that makes quite a different matter of the whole affair; and when a man speaks in that way, and his past record shows that he is *good* for all he undertakes to do, his money value is likely to come *up* instead of go down. I feel quite sure that the great world at large does not *understand* how it is that one man gets big wages and another one low wages. You may say the result of my teaching would be too many high-priced men. Not so, my friend. Every time a man is wanted to take charge of a department or of a company of men, we have hard work to find one competent. Ordinary day laborers are always in *great plenty*; but reliable men to take charge of and furnish brains to look after the muscle, there are *never* enough to go round.

I can not think of a better ending than to put right in here a letter that was put into my hands just as I dictated these last words.

Dear Friend and Brother:--I feel that I have a right to call you brother now. I write this to you first, from a sense of duty; and next because I know it will rejoice your heart to know that another of the GLEANINGS family has found the Lord. I had strayed away from God for many years; but I have the blessed assurance in my heart that I have been washed clean in the precious blood of Jesus, even if I have returned at the eleventh hour. However low down in sin I have been, I have always found time to read your Home Papers when I have had time to read GLEANINGS. Never give up those little sermons. You don't know—you can never know this side of heaven—the good they are doing. Nothing in the world would give me greater pleasure than to take you by the hand; but that may never be, perhaps, in this world. But by the dear Savior's help I expect to meet you in glory.

Your brother in Christ,
San Francisco, Cal., Apr. 27. HENRY S. THOMAS.

Dear unknown friend, you knew then, did you, that it would rejoice my heart to hear of a reader of GLEANINGS who had started out for eternal life? Now, dear brother, hold steady, and beware of the tempter. Ere many days he will try to cripple you and lead you astray. Stick to your Bible; go to your Savior every day and hour, and you will not only succeed in holding fast to the new bright life, but you will always find there are "more to follow." May God bless and strengthen you, and all the rest of the new converts that GLEANINGS reaches.

A DROUTH IN MAY.

I believe the above is something I have never known before. But there are many pleasant things about it after all. And do you know I rather enjoy these unusual features of the weather the great Father has seen fit to send us? Whenever any thing happens that the oldest inhabitant has "never seen the like of before," there are always many interesting things about it for me. In fact, I almost always find new possibilities. For instance, during this dry first of May there is no trouble in pulverizing the ground just as fine and nice as we would do in August. I have told you a good deal about our creek-bottom garden and Champion Brook. Well, this brook is worth some money just now. By the way, is there any sort of brook running through your lot? If so, you are lucky. If you haven't one, I would try to make one in the lowest part of your ground—some old natural watercourse. If you have already got it well tile-drained, have some silt-basins or little wells put along at convenient distances, for dipping up water.

Now I will tell you why you want a brook. We are again sold out of strawberry-plants—that is, we can not fill orders without taking up the plants that are to produce our fruit. But we do this rather than disappoint our customers; and as a consequence of being short we are making plants just as fast as we can by the aid of this beautiful warm sunny weather. Perhaps I should say we are making preparations for plants rather than making the plants themselves, although we have runners started already, where we have taken pains to pick out the blossom-buds and *push* them for runners. Well, our new strawberry-plantation is right alongside of Champion Brook. We plowed the ground, fined it up, mellowed it, rolled it, and marked it. Then as the plants were to be moved only a few rods, we took them up with a good chunk of dirt adhering to the plant, and set them in rows parallel with the brook. As it was Saturday (and no school), the largest part of my Sunday-school class were helping. Ordinarily I dislike to have a lot of boys transplanting, because they run about so much and tramp up the ground; and if it is the least bit wet, it gets stamped down so hard it bakes. The ground is so dry now, that, the more they stamp it with their bare feet, the more they mash up the lumps. Every thing is dry, and nice to work with.

When the plants are all in, with a ball of earth adhering, as explained above, then the boys dip water out of Champion Brook and give each plant about a pint, so it can start out housekeeping in good order. To test the value of a pint of water under such circumstances, we left one row Saturday without watering. I did this because there were indications of rain, and I thought I would see how much difference it made. Sunday, May 5, was exceedingly dry and hot—about 95 degrees in the shade, with drying winds. The plants that were not watered were most of them apparently dried up, while the others were just as fresh and bright, almost, as if they had not been moved. I went over this matter when describing the use of transplanting-tubes. We did not use tubes this time, because we found we could take up a ball of earth, with a narrow round-pointed ditching-spade, almost as well as to use the tins; and it is quite a little trouble to pick up the tins and carry them back and forth.

I do like to work soil that is dry enough so you can pulverize it and level it off and mark it out without having things stick. Then, as I said before, the running and tramping about does good rather than harm; and with water close by, say only a few rods from the plants, the whole length of the field, it is not a very big job to do the watering.

HOW TO TRAIN THE GAULT RASPBERRY FOR FRUIT.

Friend Gault—at least when I visited him—has never used any trellis at all for his raspberries. The bearing canes go up into the air, and then go down and root at the other end; and this supports them pretty well from the ground—that is, with the old canes. But his berry-patch is pretty well tangled up; and if you don't look out the vines catch on your clothing, and get broken and in disorder. We have just finished taking out the young plants, and this left a great lot of long canes trailing on the ground. It was a very difficult matter to cultivate between the rows; and another thing, the fruit would be sure to be down in the dirt unless there were some sort of support. We got out some oak stakes, 2x3 inches, and 4 feet long. These were driven, with a big sledge, at each end of the row, and some heavy galvanized wire, such as is used for grapevines, was stretched from one end of the row to the other. Then, to prevent the wire from drooping clear to the ground in the middle of the row, more similar stakes were placed, say about every 40 or 50 feet.

Now, then, we are ready to pick up these long loose canes and tie them to the wire. But I have found tying with strings to be slow business, so I got some small galvanized wire, about like that used for the lightest poultry-netting. I got a pair of tinner's shears, or snips, from the tin-shop, and wound this light wire, say a dozen times, over one of the blades of the snips. Then by shutting the shears together we had a lot of oval rings open at one side. They are shaped something like the letter U, made of wire, but the ends were pretty close together. The boys take a lot of these wire loops, slip them around their suspenders so as to have them handy when needed. With one hand they lift up a raspberry-cane, and with the other they slip a wire loop over both cane and wire; then the loose ends of the loop are twisted half a turn. Do not twist them any tighter, because after the cane has done bearing we shall need to open the loop so as to get it out and put a cane of new growth in its place. We spent quite a little money in tying up raspberry-canecanec last fall with strings; but when spring came, the motion of the wind sliding the string along the wire had cut off a great many of them. With our Palmer and Gregg raspberries we also found a good many shoots winter-killed after we had been to so much pains to tack them up to the wire. So far the Gault raspberry has never winter-killed at all; but every cane was fast at both ends. The old root was attached at one end, and the new plant at the other end. My experience is, a raspberry-cane is much safer from winter-freezing when both ends are well rooted in the ground. So long as you want to raise plants, the Gault raspberries may always be thus rooted at each end.

Now, it is some work to put up stakes and wire, and tie up the canes; but the straight rows look very much better, the picking is much easier, and then it is so much pleasanter to cultivate raspberries that are tied up. While visiting E. France I got the idea of tying blackberries to a wire in the way I have described. With the latter, however, you need taller and stronger posts, and a much heavier wire; but

for raspberries, I think the wire need not be more than $2\frac{1}{2}$ feet above the ground. This keeps them out of the dirt; and it is so low, if you want to go "crosslots" you can hold the wire down and straddle over it—that is, if you are a man of average stature.

One thing more about having your garden with rows parallel to the brook. Of course, said brook should be made to go straight through your premises. You can not afford to have it crooking as brooks usually crook. In order to have it handy for irrigation, it is not necessary that water should always be running in the brook. Scoop out some holes at intervals, and these will be filled at every summer shower. By making them of sufficient depth and length you can have water enough to keep things going, even during a very severe drouth. These remarks are intended, of course, only for using the water so you can transplant during very dry weather. After you get your stuff well going, there is seldom much need of irrigation if you keep the cultivator constantly moving, so as to preserve a mellow surface. Besides, creek bottoms, as a general thing, have more or less sand or gravel in their subsoils; and I have found this to be the case, even in heavy clay soils.

Have your brook arranged, however, with ample outlet, so that, if you have a June freshet, the water may not come clear over your stuff. In order to get rid of the effects of freshets, Champion Brook (through our ground) is from 4 to 6 feet deep, and perhaps 10 feet wide at the top, and 6 feet wide at the bottom of the channel. The sides are kept from caving in by means of cedar posts and hemlock boards. As fast as we make tin scrap in our tinshop it is packed down back of the boards, so that, by the time they rot out, the tin scrap will very likely have rusted together so as to make a permanent wall to resist the effect of high waters. Of course, we have to do more or less cleaning-out of the brook every spring.

About midway in the length of the brook, in the center of our garden, we were lucky enough to find a spring with sufficient force to raise the water 15 or 20 inches in a large iron pipe driven over this spring. This spring furnishes drinking-water all through the summer, and near where a great part of our work is done, and is worth ever so many dollars to us every summer. Now, if you have not a garden in your lowest piece of ground, with a brook running through it, you are missing lots of fun and lots of profit to one who loves to work in the ground and see things grow during a drouth.

GETTING RID OF WEEDS IN THE PLANT-BEDS.

One of the expensive drawbacks in raising vegetable-plants has been the weeding; and one trouble with the weeding is, that the boys get lazy, and lose interest when we set them to picking out the weeds between the plants, especially if the beds are very weedy. You may say we should not let the weeds go to seed. Well, we don't let them go to seed. The stable manure we are buying constantly, furnishes fresh seeds; and there is no other fertilizer as cheap and effective as stable manure.

Now I will tell you how we worked this spring. We have a larger area than heretofore, and therefore we can spare the use of a bed for a week or ten days better than when we were cramped for room. Accordingly the beds are made up as heretofore, the soil sifted so as to have the finest and best dirt on top, the bed nicely leveled over with a strip of board; and then if it does not rain it is watered and left before planting until the weeds have about all come up. Then on some hot day the surface is chopped up with a sharp steel rake, and once more sifted with a fine hand-sieve. This takes

out all the weeds, but lets the fine earth go through. Now smooth off your bed, and put in either plants or seeds, and your crop will cover the ground before weeds of any account make their appearance. In this way we get rid of weeding almost entirely, and the surface of the beds gets to be so fine it works almost like flour. If there is old rotten manure enough in it to put a rich dark color to it, this fine surface will bring up almost any thing in an incredibly short space of time; and if you put in plants they get hold and make an astonishing growth in a time that would seem almost incredible to one unacquainted with soil just right in richness and tilth. The sieve we use for this last sifting is a 10-cent square sieve for coal ashes. You can find them at almost any of the 10-cent stores. They are very light to handle, and so cheap you can afford to leave them out in the rain, without being much out of pocket.

A word more in regard to getting the soil into such a fine state of subdivision. Within a few weeks, the *Country Gentleman* has contained some excellent articles on preparation of the soil; and T. B. Terry has taken it up in the *Practical Farmer*, quoting from the *C. G.*, and adding emphasis from his experience; and I will tell you what we have been doing right along in this line during this dry month of May. We ordinarily cover our ground with a heavy coating of manure before plowing it under; but for potatoes we do the manuring the year before; therefore there is nothing to hinder working the ground up fine and soft before it is plowed. We do this with a two-horse cultivator having all the teeth in, and the roller. In fact, we get the ground fine enough to put in a crop before it is plowed at all; then when we turn it over with a plow it is finely pulverized soil down where the potatoes can make their growth. After it is plowed we fine it up again, and use tools going down deep enough to get to the fine soil turned under. I am getting to be notional about the way my plowing is done. I want the best plow I can get, and either a new point or the old one properly sharpened as soon as it becomes dull. On our creek-bottom ground we make the plow go down nine or ten inches. If it hits a stone or hard place, and then runs up, we back up the team and do it over again. After the plowing is done scientifically, then with the cutaway or Acme harrow, alternating with the roller, we get it just right, on the same principle that we fix our plant-beds, only, of course, we can not go to the trouble of sifting several acres. It is not so very expensive, when the ground is just right, to get a mellow seed-bed nine or ten inches deep. All the potatoes we raise are planted by hand. The furrows are made by Darnell's furrower and marker combined. The revolving disks make an additional fining-up, and the potatoes are finally placed with about four inches of fine mellow earth under them, and four or five inches of soft mellow earth over them. If you do this you will have a crop without any expensive commercial fertilizer, and without very much stable manure—that is, where you have a soil such as we have here in Medina. I know conditions are different away down in Florida, and possibly in other places; but with our clay soil this thorough fining and pulverizing answers to a great extent in place of the manure.

If you want more on this subject, especially fuller details, read Terry in the *Practical Farmer*, along about the first of May. The address of the publishers is Philadelphia, Pa.

Since writing about fine soil well mixed by sifting with good old well-rotted compost, I have read what our friend T. Greiner has to

say in several of the papers in regard to this very matter. In taking a small quantity of valuable potatoes, like the Craig, for instance, and increasing a single tuber to the utmost, he practices pulling off the sprouts, after they have made a leaf or two above ground, and have sent up little branching roots where the sprout is attached to the potato, a good deal as we do with the sweet potato. These sets may be pulled off and planted out; but to make a success of it you want this kind of fine rich soil I have been talking about. I suppose florists would call it *potting-soil*. There are many grades of this *potting-soil*; but when we get some that is real good it will start potato-plants, or any other kind of plants, with almost no effort or care at all. For instance, when we put out plants in our plant-beds, if the sun shines during the month of May we must both water the plants and shade them during the middle of the day, in ordinary soil; but if you have plenty of the very best kind of this *potting-soil*, if you put out good plants over night, and give them a pretty good wetting, they will have caught on to this *good* soil even during the night, so they will stand up all next day in the sun unless, indeed, it shines tremendously hot, with severe drying winds. The plants will do this with such soil where they would need to be shaded a week in ordinary garden dirt.

I have mentioned before doing quite a trade in furnishing this *potting-soil*. We get 10 cts. a peck or 25 cts. a bushel for it; and where we give a real good article, everybody thinks it is cheap, and is sure to come again. But if I am away from home, the boys are pretty apt to fill the order from some bed where it is only tolerably good. When I tell them that at this price they ought to have the very best we have—even that right out of the greenhouse-benches—they are apt to demur, and think we can not *spare* it. Why, 25 cts. a bushel would pay for clear stable manure, and we can make a very nice *potting-soil* with a half or even a fourth of well-rotted manure. A great many times we can find just the very best of this stuff where an old hogan, stable, or even poultry-house, has rotted down in some obscure corner. I think the best I have seen was where we put a great lot of poultry-manure in one of our greenhouses. I feared it would kill the plants; but by spading the ground down very deep—say more than a foot—and sifting the whole together repeatedly, it did not hurt the plants—at least very much. But it did not get to do its best until it had been worked and turned over for about one year, and then it was just beautiful to look at or to handle; and any thing that was given a chance would take hold and begin to grow almost in one night, and the plants would cover the ground, and need transplanting again, almost before one could turn his back. Oh what bright, clean, smooth-looking foliage—cabbage, celery, tomato, and every thing else! Somebody has put in a caution about getting the ground too rich for vegetable-plants. I never saw it too rich myself, providing they had plenty of sun and air, and were transplanted further apart just as soon as they began to crowd each other in the least.

HONEY FROM THE FLORIDA WILD PENNYROYAL.

Around friend Poppleton's, and at other places around Indian River, we saw a plant which they call pennyroyal. It is not a bit like the pennyroyal of the North, however, but it is rather a sort of vine with a pennyroyal taste. It spreads and grows of itself, with even just a little chance, and friend King is preparing now to plant out ten acres. I suggested moving his bees to some place where he could have *hundreds* of acres without the trouble of planting it. But he thought he could prepare and plant ten acres around his home cheaper than to move his bees, etc., to where the pennyroyal is already.

Friend King asked me the question whether bees always gather honey when the flowers yield it. Of course, I said they would; and when he went on to tell me of a time when the black mangrove yielded so much honey that it actually dropped out of the blossoms on the leaves below, and the bees would not touch it at all, I was going to accuse him of superstition. He finally explained it by saying they had a sort of salt-water fog, or spray, that covered the blossoms, bushes, and all, until the honey tasted of the salt. After they had had a good rain they washed out the salt honey, so that some more was secreted, and then the bees went at it again with a great boom.

MORE ABOUT THE SHELL MOUNDS.

Close by friend King's ranch, a spur, or side-track, branches off from the main road, and runs down to a shell mound on the banks of Indian River. This side-track is solely to take shells by the carload to the adjoining towns and cities for paving the streets. As soon as I was able to walk half a mile or more we went over to this shell mound. The shells had been shoveled away, and the track pushed off into the mound until in places a wall of solid shells rises almost perpendicularly beside the track, up fifteen or twenty feet. Was this great mound or hill made entirely of shells thrown away after some former race of people had used the contents for food? One feels a little incredulous; but as he examines the shells and finds they were broken open much as we open them now, and the large conch shells mixed in, each one of them having an opening broken in at just the right point to scoop out the edible portion, it begins to look as if it must have been the work of human beings. Besides this, at different points along up the wall of shells we see strata of dirt, debris, ashes, charcoal, and even broken pottery, indicating that the people who lived there encamped for some time on a certain spot, and that this spot was at a later date vacated and covered up with a foot or two of shells; then another encampment, and so on. Are these shells valuable only for road-making? Yes, they can be easily burned into lime, to be used for plastering houses, or to be spread on the soil where lime is needed; and some excellent results have been obtained by using these burnt shells for a fertilizer. One trouble is to get the fuel to burn them.

WAXING HONEY-BARRELS.

Before I finish up my visit at friend King's I want to speak about barrels for honey. In that warm southern clime, where frosts are so seldom known, there are great varieties of insect-enemies that we know nothing about. For instance, if you leave a boat in the water for any

I often read the piece on the third page of "Bees and Honey," and sometimes the tears blind my eyes. I know you must be a good man to meet with such wonderful success—once a laboring boy and now keeper over such wonderful works. As a rule I make things prosper along my path. I commenced empty-handed, but now it is quite different. I am bound to make the bee-business flourish in this valley. I have always kept bees, but on the old plan, which amounts to nothing.

M. A. BELLOWS, Griffin's Corners, N. Y.

length of time, the *Teredo navalis* will eat it full of holes and make it worthless; whereas, if the boat had been taken out of the water, and kept in the air, it would have been unharmed. So you see Florida is harder on slipshod managing than almost any other place. Every little while we see the results of slothfulness in beautiful boats that cost large sums of money being left in the water, to be eaten up by the teredo until they are next to worthless. Another insect delights in making little holes through the sides of honey-barrels, or any other kind. Friend King says that, no matter whether your barrels are made of oak, cypress, or any other timber, and no matter how carefully you put them away where they won't dry out, it is never safe to put honey in them until you have waxed the whole inside according to the directions so many years ago laid down in the A B C book. Wax the barrels just before they are filled, and they are safe and sound, and honey may be shipped clear to New York, without the outside becoming sticky in the least. He finds paraffine to answer just as well as beeswax, and it is very much cheaper.

Talking about shells reminds me that, while visiting Harry Mitchell, near Hawk's Park, we were shown a strip of ground in front of the house, all covered with broken shells. It was outside of the dooryard, along the main roadway, and I was much surprised to learn from friend Hart that they secured excellent crops of onions and other garden vegetables right in among these shells, although we could hardly find a bit of soil of any account.

This recalls that I omitted in the proper place to mention the very pretty little home belonging to friend Mitchell and his good wife. An artesian well of considerable volume attracted my attention in the back yard; but it was too warm, and too strongly impregnated with sulphur, to prove very palatable. Friend M. has, besides his apiary, quite a pretty yard of fruits and flowers, and a valuable collection of curiosities from Florida and other parts of the world. Although he himself is in quite poor health, we are reminded, by looking back at pages 860 to 863 inclusive, of GLEANINGS for Nov. 15, 1894, that he secured last season the enormous honey crop of 21,500 lbs. from 57 hives, or an average of about 377 lbs. per colony. If anybody has ever made a better report than this, either in Florida, California, or any other part of the world, it seems to me it can not be very much ahead, all things considered.

Sanford, Fla., is a very pretty town of about 2500 inhabitants. I was much interested in the spacious waiting-room at the depot, especially as said room contained a large open fireplace with a cheerful fire burning, made of pine logs resting on old-fashioned andirons. I had been suffering a good deal from chills, and it seemed hard work, a good many times, to get thoroughly warmed up, even down in that land of flowers and sunshine; but the big fire of pitch-pine logs filled the bill to my heart's content.

After getting well warmed up I enjoyed a walk for a couple of miles to the little station of Fort Reed, where friend McMillan has his home. Here I met with such a warm welcome from all the inmates that I did not quite understand it. My friend and his good wife, however, made haste to explain. If I am correct, they moved to Florida on account of ill health. There they found good health, but did not succeed in finding any thing suitable to their case for earning a livelihood. While thinking over the matter, and, I believe, praying over it (for they are devoted Christians), a sample copy of GLEANINGS fell into their hands. Both husband and wife soon became deeply interested, got some bees, and commenced. Although they

are well along in years, and in feeble health, as the bees increased their enthusiasm and strength seem to increase also, to meet the emergency; and right in the spot where nobody else ever thought of raising honey they have made excellent crops, and increased their bees to something like 100 colonies. Instead of selling honey at five and six cents a pound, as some others have done, friend M. started out to develop his home market. He carried samples to the big hotels, and took orders at from eight to ten cents per pound, if I remember correctly, being exceedingly careful to furnish only a first-class product, even though almost their only source of honey is the saw-palmetto; and that is why they sent me an invitation to call, and felt so glad to welcome under their own roof the man who wrote the A B C book.

I have before mentioned that a new industry has sprung up in Florida during the past winter, in the way of furnishing firewood. I was surprised to see the number of colored men with a bright new one-horse wagon, ditto harness, and a fair-looking mule with which to draw wood to town. They go out of Sanford a couple of miles, and get a very nice pine-tree, as it stands in the woods, for 25 cts. The horse stands hitched to a tree while the owner cuts up the load of wood. Then he drives to town and gets a dollar for it. I suggested, as a matter of economy, that the man employ somebody else to cut the wood while he goes with a load, thus taking ever so many more loads in a day; and I said, also, that one man could drive two horses as well as one, and thus double the output. Friend M. assured me, however, that I did not understand the colored race at all, or I would not make such suggestions. He said it was accepting considerable responsibility already for one of these men to keep his horse going every day, let alone hiring somebody to help, or, worse still, thinking of having the care and responsibility of two horses. And observation seemed to back up his assertion. Every thing is done on the one-horse plan—especially where the colored people manage it; and the one horse, instead of doing a whole day's work, stands still in his new harness, hitched to the brand-new wagon the greater part of the time.

In the vicinity of Sanford are many beautiful lakes, and some of the finest orange-groves, perhaps, in Florida. Where there was so much lamentation because the garden-stuff was killed by the frost, I suggested to quite a number of the gardeners that they try their hand at hardy vegetables that would stand a freeze: and at Sanford I found an onion-patch of nearly an acre that was comparatively unharmed. The proprietor, however, was a little above the average gardener. He had got his ground under high cultivation, and made very rich, so that the onions had vigor and vitality enough to stand the blizzard and to keep on growing.

I found one of friend McMillan's boys very busily occupied, together with a neighbor's boy, in building a boat. This boat was to be launched on Lake Jessup, within a short distance of their home. The boys were making their boat of sufficient size so they could camp out in it for several weeks, and have room enough for their provision, bedding, etc. By taking advantage of the lakes and rivers, they can get so near Indian River, that, by hiring a team to pull their boat across a mile or two, they can go clear down to Lake Worth, and from there back up to Daytona and Ormond. Of course, the vessel is to be run by sails, so the boys may, by giving their time, make quite an exploring-excursion, and see a good deal of the world, being out of pocket only what is necessary for food and clothing. A great many have made

ON PALATLAKANA RIVER.

such trips as this, and have found them, where properly managed, very enjoyable. I could not but share the boys' enthusiasm; for it brought vividly to my mind the time when I, although only 18 years of age, felt that I could not stand it any longer without seeing a little something of this great world of ours in which we live.

When I wrote up the electric gasoline-launch on pages 143 and 144, I planned to give you a picture of some of the Florida rivers with one of these pleasure-boats on it. Here it is.

A young man on the cars gave me the photo. He owns the larger of the two boats, and makes it his business to carry tourists.

ELECTROPOISE, ETC.

MORE ABOUT THE ELECTROPOISE.

Mr. Root:—I have been very much interested in your expose of humbugs and swindles, particularly that of Electropoise. You say, "If it does perform cures it is exactly in line with the idea that a horse-shoe nailed over a door wards off disease." My idea about the matter is, that a great many people have been really benefited by Electropoise, but exactly on the same principle that people are benefited by faith cure, Christian science, the waters of Lourdes, the relics of saints, the laying-on of hands, etc. If people, when they employ these remedies, thoroughly believe that they will be beneficial, then, as a result of that belief, they will be benefited.

The imagination has a very powerful influence over the functions of the human body. You say that a brass button, with a wire attached, would be just as efficacious as the Electropoise apparatus. That is undoubtedly true, provided the person using it thoroughly believed in it.

Covelo, Cal., Apr. 25.

THOS. B. HENLEY.

[Friend H., if I am correct you do not mean to reflect on a proper, right, and reasonable faith in God. I have closely inquired into the matter of faith cure, Christian science, etc., not only around my own home, but in Florida and California, and I have watched the records from other places. While there are some remarkable cases of recovery that we can not account for, there are also other instances of where both limb and life have been sacrificed because friends refuse to call in their family physician or a competent surgeon. Yes, there have been several cases of arrest of the parties because they neglected the usual and recognized means of saving life, and I think it was right and proper that people should be arrested under the circumstances. Notwithstanding, I have great faith, and with good reason, in constantly seeking God's guidance and wisdom in directing us what to do with these bodies of ours to escape sickness and death as far as possible. This Electropoise business will be the means, no doubt, of arousing people to the fact of how much imagination may do in the way of cures. But the guilty parties should be arrested in their swindling, all the same. Jesus said, "The Son of man indeed goeth as it is written of him; but woe to that man by whom the Son of man is betrayed! Good were it for that man if he had never been born." Again, "God maketh the wrath of man to praise him," it is true; but this by no means makes it right that they be allowed to go on in their wrath.—A. I. R.]

Inclosed you will find some clippings from *The Biblical Recorder*, of Raleigh, a Baptist paper. Is this Electropoise the same as you have reference to in your paper? If so, please send me some extra copies of GLEANINGS, also extra slips of the item of Prof. H. W. Wiley. I also know of a Baptist minister in my own county who sells the Electropoise, and I know of two people in my own town, whom he sold to, with no benefit—price \$25.00; but I don't know whether it is the same. If they are swindlers,

which I believe they are, I am with you to help break it up.

S. D. MATTHEWS.

Hamilton, N. C., Apr. 29.

[Yes, friend M., the circulars you send are from the very same Electropoise people we have been exposing. These people have all along based their claims on the simple fact that everybody who used their machine was either cured or made better. But here we are told of two customers receiving no benefit. The only wonder is, that anybody should receive any benefit or even *think* he had. But another appalling fact stands forth. A minister of the gospel has used his sacred calling to induce people, perhaps the members of his own church, to buy his wares; and these wares, instead of being legitimate trade and honest merchandise, are a terrible fraud and swindle—\$25.00 for that which should not cost 25 cents, and the whole thing a piece of hypocrisy and quackery at that. Religious papers have been shirking responsibility, and here is a part of the result. Friend M., show this to these poor friends who have been victimized, and advise them to demand their money back. It is a very clear case of fraud; and either the minister or the Electropoise company will hand it over very quick—probably. If they do not, tell them (the two victims) to make a plain statement in their own handwriting, and forward these statements to me.—A. I. R.]

The following from the editor of that bright new little journal, *The Market Garden*, it seems to me, throws a little light on this matter of "testimonials:"

Mr. Root:—Your stand on the Electropoise question seems to me to be worthy of no censure. I am inclined to believe your correspondent on the question in the last number of GLEANINGS has failed to understand human nature or correctly interpret her eccentricities. There are many people in the world who only need to find faith in something to find in it a panacea for their ills, the majority of which are imaginary. I am a strong believer in faith cure to the extent that, if people would only have more faith in themselves, they would have more cures than in all the patent or quack remedies under the sun. Suggestion alone is a powerful remedy; and having realized this, the cure-all people throw something in with it and reap enormous profits from the credulity of human nature. People buy the remedy, and sincerely believe they are getting well from diseases they never had, and hasten to make all sorts of testimonials, or sign those made up for them by the wise proprietors of the new medical fad.

F. W. LEAVITT.

Minneapolis, Minn.

To Keep Yourself Posted on all Electrical Frauds and Humbugs,

as well as to learn all that is interesting to know about the wonderful advancement of Electrical Art and Science, read

Electricity.

A weekly journal treating electrical subjects in a practical, non-technical and popular manner, and exposing all forms of humbuggery, quackery, and fraud, including various electro-medical devices, intended to mislead and rob those whose knowledge of electrical matters is limited.

Subscription: \$2.50 per year; sample copies free.

Electricity, 6 Park Place, New York.

[Please mention this paper.]

SWEET-CLOVER SEED WANTED.

There seems to be an unprecedented boom on this seed this year. We have handled more during the past six months, several times over, than we did in the previous six years. We are again in need of more, and should be glad to hear from any of our readers who have it for sale.

RUBBER GLOVES, SECONDS.

We have a stock of rubber gloves, Nos. 10, 11, and 12, which we bought as seconds, but which are so good that it is difficult to see wherein they are inferior to firsts. We are able to offer them postpaid, at 90c a pair. With other goods, 85c. Special rates in dozen or half-dozen lots.

CARLOAD SHIPMENTS.

As we go to press we are loading a third car, made up of export orders for New York, and have just shipped a second car to Barteldes & Co., Denver, Col. We are at work on the third car this year for Syracuse, N. Y., where F. A. Salisbury is prepared to take care of your orders for any thing in our line.

SECOND-QUALITY A B C BOOKS.

I find we have about 50 copies of the above, made up from sheets that were a little soiled or otherwise injured. They are just as good in every respect, and can be easily read—every page and every word. Until they are gone we offer them, cloth bound, at only 50 cts. each, by express or freight with other goods. If you want one by mail, add 15 cts. for postage. These are the last edition, and exactly the same as those we are selling for \$1.25.

HONEY MARKET.

We are finally closed out of comb honey entirely, except two small lots in hands of commission men in Cleveland. We have a good supply of extracted honey in cans and barrels. We have one lot of clover honey, which we will sell as it is, 350 lbs. in a barrel, at 8c, or put up in 60-lb. square cans at 9c. Choice basswood and clover honey in kegs and barrels at 7c; in 60-lb. cans, at 8½c, or two-case lots 8c. Choice Alabama honey, in barrels of about 500 lbs., at 6c. Samples mailed to those interested.

BEESWAX EASIER.

The highest point has been reached in the beeswax market, and prices are again declining slightly. We have some six or seven tons in stock, and we decline the price we pay till further notice, to 27c cash, 30c trade, for average wax delivered here. When you ship wax, be sure to put your name in or on the package, and write by mail, giving the weight of the wax shipped. We have over half a dozen lots of wax on hand now for which we can not find the owners, as they have failed to take these simple precautions when they shipped it.

DIVIDED-TOP BROOD FRAMES.

We have nine boxes, each containing 250 thick-top frames, with divided top-bar. They are just like our regular thick-top frame a year or two ago, with top-bar in two sections, each ½ inch wide. Those who like to fasten foundation in the top-bar by pinching between two pieces of wood, would find these frames convenient to use. We will sell them in the boxes, as packed, at \$2.00 a box, which is 80c per 100—about half the price of the regular thick-top frame. This is something we do not catalog, and we desire to close out this stock, hence this low price. We will not repack a less number for less than \$1.20 per 100.

BUSINESS AT THIS DATE.

We are being crowded to our utmost capacity these times—are running 12 hours a day; and if we had enough extra competent men at hand we would have a night force at work for two or three weeks, so as to turn out the goods faster. There are but few orders that have not been shipped within a week after they were received. On Tuesday, May

7, we broke all previous records by putting up 130 shipments by freight, besides quite a number by express. In the eight days ending Saturday, 11th, we received six hundred orders, and we had left unfilled at that time 250. But we had during that time shipped about as many as received, so we are really less than a week behind.

CHEAP LAWN-MOWERS.

Here is a bargain for those in want of a low-priced mower. This machine used to be our leader, and we have sold hundreds of them. Desiring to close out present stock we have cut the price down this season to less than we paid for them a few years ago. We sell the 10-inch for \$2.00, and the 12-inch for \$2.50. In lots of 3 we will discount these prices 10 per cent; 6, 15 per cent; 10 or more, 20 per cent. They are a

good light-running machine, and a bargain at these prices. We can not supply any more when present stock is sold. If you desire a bargain, let us hear from you at once.

THE MOHERMAN BRASS SPRAY-PUMP.

The adjoining cut shows a spray-pump which we secured after our list of spray-pumps was made up. It was such a decided bargain that we bought some of them. It is made on the same principle as the Myers bucket-pump. The hose is attached to a tube running up through the air-chamber. The nozzles used on the pump are the same in construction as the Myers. We can sell this one for \$2.50; by mail, \$3.25. An eight-foot pipe extension, which can not be mailed, will be included at 35 cts. extra. There are a good many spray-pumps on the market, but I doubt if you will find one equal to this at the price at which we offer it. Special prices to dealers, on application.

PROTECTING PLANTS FROM FROST, ETC.

May 13.—Well, we got some rain last Saturday, the 11th, and, more than that, it wound up with a frost last night. We had 125 large tomato-plants, many of them in blossom; and as the frost came Sunday night, it was desirable to get them covered with as little work as possible. The tomatoes were right adjoining our pie-plant patch. After a little study I directed the boys to cut off just the largest leaves from each pie-plant, and sort them out so as to put the biggest leaves over the biggest tomato-plants. The plant was carefully turned over on its side, and the great pie-plant leaf spread over the point of the leaf coming down right by the root of the plant. Then Ben, with a scoop-shovel, put a little fine dirt all around the edge of the leaf to make it tight and to hold it secure. It took perhaps half an hour, with three of us, and this morning our tomatoes are as bright and fresh as if there had been no frost at all. About an acre of kidney wax beans upon the hill were all laid flat, and the same with some Burpee's bush limas. Of course, I knew when I planted them I was taking a risk.

THE CURRANT AND GOOSEBERRY WORM.

This pest started out earlier with us than ever before, and with more persistence than ever before. We first tried hellebore, but it did not work very well, because all we could get at the drugstores was kept over from last year. Then we tried insect-

powder. This did pretty well, but it is more expensive than hellebore, and so we sent off for some fresh hellebore. This cost less, and did the business pretty well. But by this time we discovered that air-slacked lime answers just as well as either of the above, and costs practically nothing. You can use it in the bellows just the same as the insect-powder. Perhaps the amount of hellebore and pyrethrum that had been administered before we tried the lime may have had something to do with the success of the latter. The great thing with these pests is to take a stitch in time. Go over your bushes twice a day. Look carefully at the leaves out of sight down near the ground; and whenever you see half a dozen worms at work, go to work with your powder that very hour. If you wait over night, or, say, over Sunday, you may find every leaf off your bushes before you suspect that such a thing is possible.

SEED BEANS FOR FLORIDA AND OTHER SOUTHERN LOCALITIES.

I have told you something of the great bean industry of Florida, and that it commences ordinarily as early as December. From that time on, snap beans are shipped north until we can grow them here in our own locality. Well, they do not use the wax or yellow beans. They say they do not do as well as the green-podded varieties. And another thing, they can not raise good seed in the South. It all has to be brought from the North. Of course, where they get such extravagant prices for green beans in mid-winter, they want the very best seed to be had. After considerable inquiry there seems to be a pretty general agreement that a green-podded bean called "Best of All" is what is wanted. I wrote to several of our northern seedsmen in regard to the best bean for Florida, and there seemed to be a general agreement in regard to this variety. Now, I am going to undertake to furnish our southern friends with beans for seed for less than they now have to pay—four or five dollars a bushel. If some of you wish to turn in and help, I have no objection at all. I have secured 4 bushels to plant of this variety, Best of All, and can supply any of you, who want to try it, at the following prices: Pint, 15 cts.; quart, 25 cts.; peck, \$1.50. If wanted by mail, add at the rate of 8 cts. per pint, for postage and packing. When we get some nice seed, I think we can dispose of it readily by an advertisement in GLEANINGS or in some of the papers that circulate in the Southern States. So far as I can learn, it is a great yielder; and the dry beans can probably be furnished nearly if not quite as cheap as our ordinary field beans. Of course, I had to pay a high price to get the seed of this variety to start with. I wish some of the friends in Florida, who have grown the Best of All, would tell us a little more about it.

THE RECENT FROST.

Very likely the question is coming up with many of our readers as to what shall be done. Well, it wants some advice from somebody of wisdom and years of experience, many times, to say just what is best to be done. A year ago a patch of wax beans was, to all appearance, "gone up," as the boys say; but on examining closely I found buds between the leaves, that seemed to be unharmed. I waited three or four days, and had just about decided to harrow them up and plant again, when I thought I would wait a little longer. We had a warm rain, and almost every beanstalk started. I planted some more right after the frost, to see which would do better; and the frost-bitten ones gave a pretty fair crop of wax beans ten days or two weeks ahead of the others. Of course, the frost-bite set them back; but when they once got out leaves, the large root that was unharmed gave them a big send-off. At other times I think I have fussed with frost-bitten stuff when it would have been better to cultivate it up and plant anew. Sometimes you can plant between the hills or put another row alongside of the frost-bitten row. The latter way makes cultivation difficult. Putting a hill between the others does pretty well; but in gathering the crop it takes too long to hunt it up here and there; and unless it is worth considerable money it costs about all it comes to. If you decide to plant over, I would work the ground up thoroughly with cut-away or other barrows, fine it down, and roll it, as in the first place, then put in your crop just as nice as you know how. As the second planting comes right in the very best part of the season, it will oftentimes give a much better product than the first, any way; but on most things

grown by the market-gardener the prices will generally be considerably lower. Whatever you do, do not get the blues, and let your ground grow up to weeds. Get at it and do something at once.

MY NEW WHEEL FOR 1895.

I have had it some little time, but I did not mention it, because it took me some little time to decide that I liked a wheel as light as an 18-lb. Rambler. When I undertook to ride it with my winter clothing, overcoat, heavy boots, etc., somehow the wheel and I didn't get acquainted. But the warm weather came, so I could put on my light summer clothing, light shoes, etc., and I have just begun to comprehend what it is to fly through the air, with almost nothing to add to the momentum of my own weight. Well, now the wheel and I have become inseparable companions. The old one seems heavy and awkward. In fact, it is just as each succeeding lighter weight has previously thrown the others into the shade. I get on and off now with the greatest ease, and ride as slowly, if necessary, as one would walk, and go around obstacles almost easily and safely. At the same time, when I have a good stretch of road there seems to be almost no limit to the speed that may be attained. By the way, I wonder if the next great move in this world of ours is not going to be along the line of dropping useless weights and encumbrances; or, to put it in a spiritual sense, to "lay aside every weight, and the sin that doth so easily beset us, and run the race that is set before us." Somehow I seem to have gotten my text at the end of my little sermon; but, my good friend, if you do not weigh any more than about 130 or 140 lbs., and if you have never tried an 18-lb. wheel of the present date, let me suggest to you that there is a treat in store for you. By the way, I have not had any long rides yet this season, principally because my presence seems at this season to be so urgently needed every day here at the Home of the Honey-bees.

Kind Words From Our Customers.

The Crane smoker you sent me is the best I ever saw.
W. B. AIRKIN.
Riverside, Tex.

My goods were received O. K. They are the finest I have seen. You may look for my future orders.
HENRY E. LIVELING.
East St. Louis, Ill., April 27.

The garden seeds I ordered of you by mail came all right in just four days from the day I ordered them. We get just about twice as many seeds for the money from you as we can at the stores here. Please accept thanks.
MAD TALBERT.
Morristown, Ind., Mar. 11.

The goods ordered Apr. 4th arrived safely and in good condition; also the queen ordered on the 8th. She has been introduced successfully. My reason for ordering goods of you in preference to buying nearer home is, that I am always sure of their coming in good condition.
W. W. CONNER.
Washington, D. C., April 29.

ONE BIG COLONY WORTH TWO OR THREE SMALL ONES.

I make just as few swarms as possible, as one large swarm gathers as much honey as three or four small ones. The bad windy days for handling bees I am busy making or putting together and painting those new hives I got from you, which are the nicest you ever sent me. You have really outdone yourself on this order.
H. T. GIFFORD.
Vero, Fla., April 22.

Your card of the 16th ult. is at hand, also GLEANINGS for March 1st. In reply to your request for posts regarding "hive argument," I say keep it up and we will sift the grain from the chaff. GLEANINGS is getting better each year, and all are given a fair hearing. Bloom is coming on, and bees are rearing brood very fast. Prospects are very good for a fair crop.
J. W. GRIFFIN.
Descanso, Cal., Mar. 8.

"The Battle Is Not To The Strong Alone"

If it were, we would win it just as we do now, for we stand ready to guarantee our fence to be the **strongest** of all wire fences made. We do not ask you to take anybody's figures or tables of tensile strength, but will make a bona fide test of the real article. On the other hand, if a fence must be "vigilant," "active" and "brave," there is no use looking further than the Page. It's the only **live** fence. "Dead" **soft** wire fences are exempt. **PAGE WOVEN WIRE FENCE CO., Adrian, Mich.**

In a recent advertisement we told of our very superior all-steel hand and power feed cutter to be offered at

\$10 worth \$40

Another ad. tells of the process of galvanizing and its indispensable preservative qualities. We also will give you the experience of two representative business firms of Illinois, one of whom has sold 400 and the other 500 Aeromotors. In ad. No. 4 we give a price on the best pumps made, hand, windmill, and irrigation, lower than was ever before dreamed of, and in ad. No. 5 we talk to you of steel galvanized tanks, with covers, at the unheard of price of 2½ cents per gallon. This is cheaper than wood. They do not shrink, leak, rot, rust, or give taste to water. Read all of the Aeromotor ads.

The Aeromotor Company treats the public generously. While state legislatures are passing laws to secure repairs for farm machinery at reasonable prices, **IT IS A FACT THAT THE AEROMOTOR COMPANY HAS FOR THE YEAR 1895 BEEN COMPELLED TO RAISE ITS PRICES ON REPAIRS BECAUSE SOME OF ITS CUSTOMERS HAVE BEEN ORDERING INDIVIDUAL PARTS TO MAKE UP COMPLETE MACHINES, SINCE IN THAT WAY THEY COULD GET A MACHINE CHEAPER THAN BY ORDERING IT ASSEMBLED.** People

are not compelled to buy

parts to buy repairs.

It is in this respect generally so low that customers could buy the repairs and change at less than the machine would cost. But not certain that they assembled in good shape, own reputation, the Aeromotor price of certain repairs in future. Not only has the given the best goods at the lowest price at an invoice, but **TWENTY BRANCH HOUSES THE COUNTRY IN ORDER GOODS EASILY ACCESSIBLE REPAIRS WITHIN EASY TO greatly increase this a matter of the greatest are purchasing machinery. a wise man will look to it that repairs can quickly cost. Our very low prices and high standards on everything connected with water supply and power production by wind, together with the accessibility of a full line of our goods and repairs, will be appreciated.**

machinery; they are compelled to raise their prices.

The Aeromotor Company is not a fault.

It is not certain that they assembled in good shape,

own reputation, the Aeromotor price of certain repairs in future.

Not only has the given the best goods at the lowest price at an invoice, but

TWENTY BRANCH HOUSES THE COUNTRY IN ORDER GOODS EASILY ACCESSIBLE REPAIRS WITHIN EASY TO greatly increase this

a matter of the greatest are purchasing machinery.

a wise man will look to it that repairs can quickly cost.

Our very low prices and high standards on everything connected with water supply and power production by wind,

together with the accessibility of a full line of our goods and repairs, will be appreciated.

Aeromotor Co., Chicago.

METAL WHEELS for your WAGONS.

Any size you want, 20 to 56 in high. Tires 1 to 8 in wide—hubs to fit any axle. Saves Cost many times in a season to have set of low wheels to fit your wagon for hauling grain, fodder, manure, bogs, &c. No resetting of tires. Cat's free. Address **EMPIRE MFG. CO., Quincy, Ill.**

In responding to this advertisement mention GLEANINGS.

Promptness is What Counts.

Honey-jars, Shipping-cases, and every thing that bee-keepers use. **Root's Goods at Root's Prices, and the Best Shipping-point in the Country.** Dealers in Honey and Beeswax. Catalog free.

WALTER S. POWDER,
162 Massachusetts Ave., Indianapolis, Ind.
Please mention this paper.

Crane Smoker 1895 Pattern.

This excellent smoker was introduced some two years ago, since which time it has worked itself rapidly into popular favor.

Patented March 12, 1895.

Its Distinctive Feature is the Crane Valve, by which the full force of the bellows is secured without waste, and by which also smoke is prevented absolutely from going into the bellows.

The Legs are of Skeleton Malleable Iron, contracted at the feet so as to be out of the way of the fingers in handling, and are secured to the bellows by bolts instead of screws.

The Shield is of Light Corrugated Tin, and bags next to the bellows, thus giving ample protection from heat.

The Cone Top easily tilts back for replenishing the smoker, and is secured by a malleable-iron hinge, the working parts of which are milled so as to insure accurate adjustment to the stove or cup.

As to Fuel, it will burn any thing, including Soft Coal, Stovewood, Planer-shavings; and it makes no difference how much the latter may be crammed down in the cup, there will be the same strong blast as before.

Price, 3½-inch barrel, \$1.85, post-paid; or \$1.50 by fgt. or exp.

The A. I. Root Company,
Medina, Ohio.

Notice!

We beg to announce that we have completed arrangements with the Porters whereby we secure for this country the control of the sale of that very excellent and almost indispensable implement,

The Porter Bee-Escape.

It will be manufactured by the Porters, as formerly, but write to us for prices in both large and small quantities.

The A. I. Root Co., Medina, O.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—The stock of comb honey is large; market well supplied. Fancy white 1-lb. combs, 13; amber, 11. Receipts of extracted, white, 7; amber, 5½@6; Southern, 4½@5. Beeswax, 22.
HAMLIN & BEARSS,
Kansas City, Mo.

CHICAGO.—*Honey.*—There is not much honey being sold, and prices remain as formerly reported. Such white comb as we have of good quality sells at 14c; but there is a prospect that the market is going to be cleaned out before new crop. Extracted brings 5½@7. Beeswax, fair grade, 30c.

R. A. BURNETT & CO.,
163 So. Water St., Chicago, Ill.

DETROIT.—*Honey.*—Honey is somewhat neglected. Prices lower, with little good in sight. Best white comb honey 13@14; dark lots at buyers' prices. Extracted, 6@7. Beeswax, 29@30.

M. H. HUNT,
Bell Branch, Mich.

CLEVELAND.—*Honey.*—Our honey market is very slow. No. 1 white, in 1-lb. sections, 12@13c; No. 2, 11; extracted, No. 1 white, 7@8. Beeswax, 28c.

WILLIAMS BROS.,
80 & 82 Broadway, Cleveland, O.

CINCINNATI.—*Honey.*—The market is quiet. No change since our last. We quote choice comb honey at 12@16c. Extracted honey at 4@7. Demand is good for beeswax at 25@31 cts. on arrival for good to choice yellow.
CHAS. F. MUTH & SON,
Cincinnati, O.

ST. LOUIS.—*Honey.*—The market for strained honey in barrels and cans is more active—prices, however, not improving. We quote comb, 10@12; extracted, in cans, 5½@6½; in barrels, 4½@5. Prime beeswax, 27.
D. G. TUTT GROCER CO.,
St. Louis, Mo.

KANSAS CITY.—*Honey.*—The demand for comb honey is light; considerable on the market. Receipts of extracted light, demand fair. We quote No. 1 white comb, 13@14; No. 2, 1-lb., 12@13; No. 1 amber, 12@13; No. 2, 8@10; extracted, 5@7. Beeswax, 25.
C. C. CLEMONS & Co.,
Kansas City, Mo.

PHILADELPHIA.—*Honey.*—Comb honey finds little or no sale now in large city. Extracted is selling freely. We quote comb honey, 9; extracted, 5½. Beeswax, 30c for clear yellow.

WM. A. SELSER,
10 Vine St., Philadelphia, Pa.

BUFFALO.—*Honey.*—The honey market is very active and sales are light. Fancy, 12@13; choice, 10@11. Most of the stock on hand is tail ends of shipments. Cleaning up at irregular prices. Buckwheat, very slow sale at prices ranging from 6@8c. Extracted is dull. Beeswax, 28@30c.

BATTERSON & Co.,
Buffalo, N. Y.

BOSTON.—*Honey.*—Our honey market is quiet and without change. We quote your market at 13 @14 for best 1-lb. comb honey, and 5@6 for extracted, with light demand.
E. E. BLAKE & Co.,
Boston, Mass.

ALBANY.—*Honey.*—Our market is well cleaned up on both comb and extracted honey. We have a small stock of buckwheat, but no clover on hand. There is but very little demand, and prices remain unchanged. Have had some correspondence with Florida parties desiring to ship new honey.

CHAS. McCULLOCH & Co.,
Albany, N. Y.

SAN FRANCISCO.—*Honey.*—The prospects for the coming honey crop are good, and we expect to ship large quantities of California honey to the East. I quote to-day: New extracted honey, light amber, 5c; white, 5½. White comb, 1-lb. frame, 10. Beeswax, 26@27.

HENRY SCHACHT,
Successor to Schucht, Lemcke & Steiner,
San Francisco, Cal.

NEW YORK.—*Honey.*—All grades of white comb honey are well cleaned up. Considerable buckwheat is yet on the market, and, as the demand is about over, some of it will probably be carried over. We quote white, 10@12, and buckwheat 7@8. There is a fairly good demand, principally for California, of which there is more than a sufficient supply to meet the demand. New crop southern is arriving quite freely. We quote: California, 5½@6; white-clover and basswood, 6; buckwheat, 5; southern, common to fair, per gallon, 45@50; choice, 55@65. While beeswax holds firm at 31@32, we think the market has reached top prices, and do not expect it to advance any further.

HILDRETH BROS. & SEGELKEN,
120 & 122 W. Broadway, New York.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty.

J. P. IVY,
Secretary Bee-keepers' Association,
Phoenix, Maricopa Co., Arizona.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c.

OLIVER FOSTER, Las Animas, Col.

No. 1 extracted honey in 50-lb. pails at 7c per lb.—\$3.50. J. B. MURRAY, Ada, O.

BUFFALO, N. Y. Unsurpassed Honey Market.
BATTERSON & CO. Responsible, Reliable,
Commission Merchants. 18tfdb and Prompt.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All advertisements intended for this department must not exceed five lines, and you must say you want your advt in this department, or we will not be responsible for errors. You can have the notice as many lines as you please, but all over five lines will cost you according to our regular rates. This department is intended only for bona fide exchanges. Exchanges for cash or for price lists, or notices of offering articles for sale, can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

WANTED.—To exchange 200 colonies of bees for any thing useful on plantation.
ANTHONY OPP, Helena, Ark.

WANTED.—To exchange several good safety bicycles. Honey wanted. Send sample.
J. A. GREEN, Ottawa, Ill.

WANTED.—To exchange 6 and 12 inch Root foundation mills for wax, honey, or offers.
I. J. STRINGHAM, 105 Park Place, New York, N. Y.

WANTED.—To exchange supplies and other goods for honey. O. H. HYATT, Shenandoah, Iowa, 20tf

WANTED.—To exchange a quantity of carpenters' tools, also Barred Plymouth Rock eggs for nuclei.
F. L. WOTTON, Darien, N. Y.

WANTED.—To exchange golden queens for Pekin ducks, Embden geese, fancy poultry, buckwheat.
J. F. MARKE,
Greenville, Darke Co., Ohio.

WANTED.—To exchange 26-in. planer, power scroll saw, all iron; tenoner, and mortiser, for portable sawmill, or other wood-working machinery. Will give a bargain for cash.
eif GEO. RALL, Frenchville, Trempe Co., Wis.

Boardman's Bee-Feeder.

You can not afford to let your bees run down before the honey-flow begins. By stimulative feeding you can have a strong working force of bees ready for business in honey harvest. For feeding under all conditions, and especially for stimulative feeding, there is no feeder quite as safe and convenient as the

Boardman Feeder.

I am prepared to furnish them in large and small quantities. Particulars and prices on application to

H. R. BOARDMAN,

East Townsend, - - Huron Co., - - Ohio.

FOR SALE.—JAPANESE BUCKWHEAT, 75 CTS. PER BUSHEL.
A. P. LAWRENCE,
HICKORY CORNERS, MICH.

Black and Hybrid Queens For Sale.

100 black, hybrid, and mismatched queens for sale; 30c each; \$3.00 per doz.

H. L. WEENES, Hanford, Cal.

"The Southland Queen."

Send \$1.00 for the Southland Queen. Edited by the Atchley family. Plain, practical, and all fresh bee matter. Jennie Atchley will begin a Bee-keeping school in June 15th No. All that wish lessons, come in. A steam bee-hive factory, Root's goods, Dadant's foundation. Send for free catalog and sample journal.

THE JENNIE ATCHLEY CO.,
Beeville, Bee Co., Texas.

CASH FOR BEESWAX

Will pay 25c per lb. cash, or 28c in trade, for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 33c for best selected wax. Old combs not be accepted under any consideration.

Unless you put your name on the box, and notify us by mail of amount sent, we can not hold ourselves responsible for mistakes. It will not pay as a general thing to send wax by express.

THE A. I. ROOT CO., Medina, O.

Second-Hand Bicycles Cheap.

We have the following second-hand bicycles for sale at the prices stated:

One ladies' Victoria, last year's model, made by the Overman Wheel Company; has been used but little, and cost last year \$125.00. Will sell for \$65.

One ladies' Monarch, last year's model, for \$55.

One ladies' Columbia, '92 pattern, in perfect running order, tires in good condition; price \$37.50.

One gent's Columbia, '93 pattern, also in perfect order, with new tires, and newly enameled, \$47.50.

One gent's Monarch, '93 pattern. This wheel has had considerable use, but is in good condition. Has had new tires recently; weighs about 30 lbs. \$45.

One gent's Lovell Diamond, '93 pattern. Fitted with new tires and pedals last fall. Weighs about 31 lbs. In excellent condition, and a bargain at the price. \$40.

We have also one \$16.00 shot-gun, nearly new, 12 bore, breech-loading, top action; barrels perfect, and without a spot inside or out; modified choke; for only \$11.

Will take white honey or wax in trade, f.o.b. at Medina, for any of above goods.

THE A. I. ROOT CO., Medina, Ohio.

A KIND WORD FOR THE BOOK "THE CHRISTIAN'S SECRET OF A HAPPY LIFE."

The following is from a private letter to one of the teachers in the Medina schools, and was not written for publication.

Dear Sarah:—I much wish to give a number of Japanese of my acquaintance, who read English, the book Christian's Secret of a Happy Life. I know of nothing that is more needed in Japan than such teaching as that. Our best (or, rather, leading) men are doubting or unbelieving in the divinity of Christ, the resurrection, the personality of God, etc., so that it seems as if they had no greatly different foundation from Buddhists. A lack of spirituality and vital faith in a living Savior is, I believe, the root of the difficulty. I am having the book translated into Japanese, but it will take a good while to get it done, and I want to give one or two discouraged friends (pastors) the book right away.

H. FRANCES PARMELEE.

Maebashi Joshu, Japan, April 23.

[Our missionary friend has, without knowing it, given us one of the grandest testimonials for this good book I have ever seen, for it does indeed strike directly at the root of the matter. I am afraid that right here in America as well as in Japan we have "discouraged pastors;" and this book, "The Christian's Secret of a Happy Life," has a most kind and genial rebuke to all such. "O thou of little faith! wherefore didst thou doubt?"]

A. I. R.

Books for Bee-Keepers and others.

Any of these books on which postage is not given will be forwarded by mail, postpaid, on receipt of price.

In buying books, as every thing else, we are liable to disappointment if we make a purchase without seeing the article. Admitting that the bookseller could read all the books he offers, as he has them for sale, it were hardly to be expected he would be the one to mention all the faults, as well as good things about a book. I very much desire that those who favor me with their patronage shall not be disappointed, and therefore I am going to try to prevent it by mentioning all the faults, so far as I can, that the purchaser may know what he is getting. In the following list, books that I approve I have marked with a *; those I especially approve, **; those that are not up to times, †; books that contain but little matter for the price, large type, and much space between the lines; ‡; foreign, §. The bee-books are all good.

BIBLES, HYMN-BOOKS, AND OTHER GOOD BOOKS.

As many of the bee-books are sent with other goods by freight or express, incurring no postage, we give prices separately. You will notice, that you can judge of the size of the books very well by the amount required for postage on each.

- 8 Bible, *good print*, neatly bound..... 20
 - 10 Bunyan's Pilgrim's Progress**..... 30
 - 20 Illustrated Pilgrim's Progress**..... 75
- This is a large book of 425 pages and 175 illustrations, and would usually be called a \$2.00 book. A splendid book to present to children. Sold in gilt edge for 25c more.

6 First Steps for Little Feet. By the author of the Story of the Bible. A better book for young children can not be found in the whole round of literature, and at the same time there can hardly be found a more attractive book. Beautifully bound, and fully illustrated. Price 50 c. Two copies will be sold for 75 cents. Postage six cents each.

- 5 Harmony of the Gospels..... 35
- 3 John Ploughman's Talks and Pictures, by Rev. C. H. Spurgeon*..... 10
- 1 Gospel Hymns, consolidated Nos. 1, 2, 3, and 4, words only, cloth, 10 c; paper..... 05
- 2 Same, board covers..... 20
- 5 Same, words and music, small type, board covers..... 45
- 10 Same, words and music, board covers..... 75
- 3 New Testament in pretty flexible covers..... 05
- 5 New Testament, new version, paper covers..... 10
- 5 Robinson Crusoe, paper cover..... 10
- 4 Stepping Heavenward**..... 18
- 15 Story of the Bible**..... 1 00

A large book of 700 pages, and 274 illustrations. Will be read by almost every child.

- 5 The Christian's Secret of a Happy Life**..... 25
- 8 Same in cloth binding..... 50
- 1 "The Life of Trust," by Geo. Muller**..... 1 25
- 1 Ten Nights in a Bar-Room, T. S. Arthur*..... 05
- 5 Tobacco Manual**..... 45

This is a nice book that will be sure to be read, if left around where the boys get hold of it, and any boy that reads it will be pretty safe from the tobacco habit.

BOOKS ESPECIALLY FOR BEE-KEEPERS.

- Postage..... (Price without postage.)
- 15 A B C of Bee Culture. Cloth..... 1 10
- 5 A Year Among the Bees, by C. C. Miller..... 45
- 5 Advanced Bee Culture, by W. Z. Hutchinson..... 50
- 3 Amateur Bee-keeper, by J. W. Rouse..... 22
- 14 Bees and Bee-keeping, by Frank Cheshire, England. Vol. I. s..... 2 36
- 21 Same, Vol. II. s..... 2 79
- or, \$5.25 for the two, postpaid.
- 10 Bees and Honey, by T. G. Newman..... 90
- 5 Cook's New Manual. Cloth..... 1 15
- 5 Doolittle on Queen-Rearing..... 95
- 2 Dzierzon Theory..... 10
- 3 Foul Brood; Its Natural History and Rational Treatment..... 22

- 5 The Honey Bee, by Thos. William Cowan..... 25
- British Bee-keeper's Guide Book, by Thos. William Cowan, England..... 40
- 3 Merrybanks and His Neighbor, by A. L. Root..... 15
- 4 Winter Problem in Bee-keeping, by Pierce..... 46

MISCELLANEOUS HAND-BOOKS.

- 5 An Egg-Farm, Stoddard**..... 45
 - 1 Amateur Photographer's Hand-book**..... 70
 - 3 A B C of Potato Culture, Terry**..... 35
- This is T. B. Terry's first and most masterly work. The book has had an enormous sale, and has been reprinted in foreign languages. When we author the highly competent with friend Terry's system of raising potatoes, we shall be ready to handle almost any farm crop successfully. It has 48 pages and 22 illustrations.

- 5 A B C of Carp Culture, by Geo. Finley..... 35
 - 5 A B C of Strawberry Culture** By T. B. Terry..... 35
- Probably the leading book of the world on strawberries.

- 1 Barn Plans and Out-Buildings*..... 1 50
- 2 Canary Birds. Paper..... 50
- 2 Celery for Profit, by T. Greiner**..... 25

The first really full and complete book on celery culture, at a moderate price, that we have had. It is full of pictures, and the whole thing is made so plain that a schoolboy ought to be able to grow paying crops at once, without any assistance except from the book.

- 8 Domestic Economy, by I. H. Mayer, M. D.** 60
- This book ought to save at least the money it costs, each year, in every household. It was written by a doctor, and one who has made the matter of domestic economy a life study. The regular price of the book is \$1.00; but by taking a large lot of them we are enabled to make the price only 60 cts.

- 10 Draining for Profit and Health, Warring..... 1 50
- 10 Fuller's Grape Culturist**..... 1 40
- 5 Farming for Boys*..... 75

This is one of Joseph Harris' happiest productions, and it seems to me that it ought to make farm-life fascinating to any boy who has any sort of taste for gardening.

- 7 Farm, Gardening, and Seed-Growing*..... 90
- This is by Francis Brill, the veteran seed-grower, and is the only book on gardening that I am aware of that tells how market-gardeners and seed-growers raise and harvest their own seeds. It has 166 pages.

- 12 Gardening for Pleasure, Henderson*..... 1 85
- While "Gardening for Profit" is written with a view of making gardening pay, it touches a good deal on the pleasure part; and "Gardening for Pleasure" takes up this matter of beautifying your homes and improving your grounds without the special point in view of making money out of it. I think most of you will need this if you get "Gardening for Profit." This work has 404 pages and 203 illustrations.

- 12 Gardening for Profit..... 1 85
- The latest revision of Peter Henderson's celebrated work. Nothing that has ever before been put in print has done so much toward making market-gardening a science and a fascinating industry. Peter Henderson stands at the head, without question, although we have many other books on these rural employments, but no one can afford to buy but one book, let it be the above. It has 376 pages and 138 cuts.

- 1 Gardening for Young and Old, Harris**..... 1 25
- This is Joseph Harris' best and happiest effort. Although it goes over the same ground occupied by Peter Henderson, it particularly emphasizes thorough cultivation of the soil in preparing your ground; and this matter of adapting it to young people as well as to the old is a great thing to be kept in view. If your children have any sort of fancy for gardening it will pay you to make them a present of this book. It has 187 pages and 46 engravings.

- 10 Garden and Farm Topics, Henderson**..... 75
- Gray's School and Field Book of Botany..... 1 80
- 5 Gregory on Cabbages; paper*..... 25
- 5 Gregory on Squashes; paper*..... 25
- 5 Gregory on Onions; paper*..... 25

The above three books, by our friend Gregory, are all valuable. The book on squashes especially is good reading for almost anybody, whether they raise squashes or not. It strikes at the very foundation of success in almost any kind of business.

- 10 Greenhouse Construction**..... 1 40
- This book, by Prof. Taft, is just out, and is as full and complete in regard to the BUILDING of all glass structures as is the best book in regard to their management. Any one who builds even a small structure for plant-growing under glass will save the value of the book by reading it carefully.

- 15 How to Make the Garden Pay**..... 1 35
- By T. Greiner. This is a new book, just out, and it gives the most explicit and full directions for gardening under glass of any book in the world. Those who are interested in hot-beds, cold-frames, cold-greenhouses, hot-houses or glass structures of any kind for the growth of plants, can not afford to be without the book.

- 1 Handbook for Lumbermen..... 10
- 10 Household Conveniences..... 1 40
- 2 How to Propagate and Grow Fruit, Green*..... 15
- 2 Injurious Insects, Cook..... 25
- 10 Irrigation for the Farm, Garden, and Orchard, Stewart*..... 1 40

This book, so far as I am informed, is almost the only work on this matter that is attracting so much interest, especially recently. Using water from springs, brooks, or windmills, to beat the place of rain, during our great drought, is a great problem before us at the present day. The book has 274 pages and 142 cuts.

- 5 Manures; How to Make and How to Use them; in paper covers..... 45
- 6 The Same in cloth covers..... 65

Covering the whole matter, and discussing every thing to be found on the farm, refuse from factories, mineral fertilizers from manure, and a complete summing-up of the whole matter. It is written by F. W. Semper.

- 7 Market-gardening and Farm Notes, by Burnett Landreth..... 90

The Landreths are the pioneer seedsmen of America; and the book is worth fully as much as we might expect it to be. I think I received it from it worth its price, before I had been in my hands fifteen minutes. It is exceedingly practical, and tells what has been done and what is BEING done, more than it discourses on theory.

- 3 Maple Sugar and the Sugar-bush**..... 35
- By Prof. A. J. Cook. This was written in the spring of 1887 at my request. As the author has, perhaps, one of the finest sugar-camps in the United States, as well as being an enthusiastic lover of all farm industries, he is better fitted, perhaps, to handle the subject than any other man. The book is written

in Prof. Cook's happy styl combining wholesome moral lessons with the latest and best method of managing to get the finest syrup and maple sugar, with the least possible expenditure of cash and labor. Everybody who makes sugar or molasses will save the sugar-book. It has 42 pages and 35 cuts.

1 | Our Farming, by T. B. Terry**..... \$2.00
in which he tells "how we have made a run-down farm bring both profit and pleasure."

This is a large book, 6x9 inches, 367 pages, quite fully illustrated. It is Terry's first large book; and while it touches on the topics treated in his smaller handbooks, it is sufficiently different so that no one will complain of repetitiveness, even if he has read all of Terry's little books. I should call it the brightest and most practical book on farming before the world at the present day. The price is \$2.00 postpaid; or clubbed with GLEANINGS for 2.50. Those who are already subscribers to GLEANINGS may have it postpaid by sending us 1.50 more. We are so sure it will be worth many times its cost that we are not afraid to offer to take it back if any one feels he has not got his money's worth after he has read it. If ordered by express or freight with other goods, 10c less.

3 | Onions for Profit**..... 45
Fully up to the times, and includes both the old onion culture and the new method. The book is fully illustrated, and written with the enthusiasm and interest that characterize its author, T. Greiner. Even if one is not particularly interested in the business, almost any person who picks up Greiner's books will like to read them through.

1 | Poultry for Pleasure and Profit**..... 10
11 | Practical Floriculture, Henderson*..... 1 35
10 | Profits in Poultry*..... 90
2 | Practical Turkey-raising..... 10
By Fanny Field. This is a 25-cent book which we offer for 10 cts.; postage, 2 cts.

4 | Peabody's Webster's Dictionary..... 10
Over 30,000 words and 250 illustrations.

2 | Rats: How to Rid Farms and Buildings of them, as well as other Pests of like Character..... 15

This little book ought to be worth dollars instead of the few cents it costs to any one who has ever been troubled with these pests, and who has not! It is written in such a happy vein that every member of the family will read it clear through, just about as soon as they get hold of it. It contains a complete summing up of the best information the world can furnish.

1 | Silk and the Silkworm..... 10
11 | Small-Fruit Culturist, Fuller..... 1 40
10 | Success in Market-Gardening*..... 90

This is a new book by a real, live, enterprising, successful market-gardener who lives in Arlington, a suburb of Boston Mass. Friend Rawson has been one of the foremost to make irrigation a practical success, and he now irrigates his grounds by means of a windmill and steam-engine whenever a drought threatens to injure the crops. The book has 208 pages, and is nicely illustrated with 110 engravings.

1 | Ten Acres Enough..... 1 00
1 | Talks on Manures*..... 1 75

This book, by Joseph Harris is, perhaps, the most comprehensive one we have on the subject, and the whole matter is considered by an able writer. It contains 366 pages.

2 | The Carpenter's Steel Square and its Uses..... 15
10 | The New Agriculture; or, the Waters Led Captive..... 75

2 | Treatise on the Horse and his Diseases..... 10
5 | Tile Drainage, by W. I. Chamberlain..... 35
Fully illustrated, containing every thing of importance clear up to the present date.

The single chapter on digging ditches, with the illustrations given by Prof. Chamberlain, should alone make the book worth what it costs, to every one who has occasion to lay ten rods or more of tile. There is as much science in digging as in doing almost any thing else; and by following the plan directed in this book, one man will often do as much as two men without this knowledge. The book embraces every thing connected with the subject, and was written by the author while he was engaged in the work of digging the ditches and laying the tiles HIMSELF, for he has laid literally miles of tile on his own farm in Hudson, O.

5 | Tomato Culture..... 35

In three parts. Part first—by J. W. Day, of Crystal Springs, Miss., treats of tomato culture in the South, with some remarks by A. I. Root, adapting it to the North. Part second—By D. Cummins, of Conneaut, O., treats of tomato culture especially for canning-factories. Part third—By A. I. Root, treats of plant-growing for market, and high-pressure gardening in general. This little book is interesting because it is one of the first rural books to come from our friends in the South. It tells of a great industry that has been steadily growing for some years past; namely, tomato-growing in the South to supply the Northern markets. The little book, which is fully illustrated, gives us some pleasant glimpses of the possibilities and probabilities of the future of Southern agriculture. Even though you do not grow tomatoes to any considerable extent, you will find the book brimful of suggestions of short cuts in agriculture and horticulture, and especially in the line of market-gardening.

3 | Winter Care of Horses and Cattle..... 35
This is friend Terry's second book in regard to matters of this kind, but it is so intimately connected with his potato-book that it reads almost like a sequel to it. If you have only a horse or a cow, I think it will pay you to invest in the book. It has 44 pages and 4 cuts.

3 | Wood's Common Objects of the Microscope**..... 47

8 | What to Do and How to be Happy While Doing It, by A. I. Root..... 50

THE A. I. ROOT CO., MEDINA, O.

B EES, 60 Cents a Pound, this month.

T. P. Andrews, Farina, Fay, Co., Ill.

WHY NOT

Send your orders to W. H. Laws for Italian Queens?

THE BEST IS THE CHEAPEST.

For beauty and business you can't beat them. The leading bee-keepers of the U. S. are my customers, and all praise them. I breed either the Golden or Leather-colored strains.

PRICES REDUCED

To suit the times. Fine breeders always on hand, \$2 to \$3. Untested, 75c; 3 for \$2. Tested, \$1; 6 for \$5. Address

W. H. LAWS, LAVACA, ARK.
Please mention GLEANINGS.

Look Here, Bee-keeper!

If you are in need of bee-supplies, write for catalog and price list. Every thing sold as cheap as the cheapest.

Kenton, Hardin Co., O. **W. E. Smith.**

A Tested Queen Free!

Pure Italians. To every one buying 1½ doz. untested queens I will give a tested one free. Untested, 60c; tested, \$1.00; selected tested, \$1.50; breeders, \$3.00.

STEWART BROS., Sparta, Tenn.

In responding to this advertisement mention GLEANINGS.

MUTH'S HONEY-EXTRACTOR, SQUARE GLASS HONEY-JARS.

Bee-keepers' Supplies in general, etc., etc. Send for our new catalog. "Practical Hints" will be mailed for 10c in stamps. Apply to

CHAS. F. MUTH & SON, Cincinnati, O.

Given Foundation

Ready for Delivery.

We are now making, as previously announced, Given foundation on rolls. We can supply the product at the same price as the regular wax. Customers who desire a small quantity to experiment with can have a little added to the regular foundation if they will so specify in their orders. We neither indorse nor condemn it, but hope it will be tried sufficiently to test its merits. The surplus Given has extra thin bases. **The A. I. Root Co., Medina, O.**

W. O. Victor, of Wharton, Tex., took

45,000 Lbs. of Honey in 1894.

He offers Italian Queens—good, old-style honey-queens—untested, first order, to any address, at 50c each. Also bees in any quantity; 450 colonies to draw from. Root's goods constantly in stock. Prices to suit the times. Buy near home, and save freight.

ITALIAN BEES Ready in May. Queens, \$1.00. Bees by the pound, \$1.00. One-

AND QUEENS. frame nucleus with queen, \$2.00; two frames, \$2.50. Also Barred

Plymouth Rock eggs for setting, \$1.00 per 15.

6-17el **MRS. A. A. SIMPSON, SWARTS, PA.**

Eggs From 8 leading varieties of fowls, including Imperial Pekin Ducks. Send for descriptive list to **J. S. MASON, Medina, O.**

In writing advertisers mention this paper.

TESTED QUEENS

Are usually sold for \$2.00. I will explain why I wish to sell a few at less than that. As most of my readers know, I require my apiary each spring with young queens from the South. This is done to do away with swarming. If done early enough it is usually successful. It will be seen that the queens displaced by these young queens are never more than a year old; in fact, they are fine, tested, Italian queens, RIGHT IN THEIR PRIME; yet, in order that they may move off quickly, and thus make room for the untested queens, they will be sold for only **ONE DOLLAR**. Or I will send the **REVIEW** for 1895 and one of these queens for only \$1.75. For \$2.00 I will send the **REVIEW**, the queen, and the book "Advanced Bee Culture." If any prefer the young, laying queens from the South, they can have them instead of the tested queens, at the same price. A discount on large orders for untested queens. Say how many are wanted, and a price will be made. Orders can be filled as soon as it is warm enough to handle bees and ship queens with safety.

FEEDING.

HOW THE AXTELLS DO IT.

By Mrs. L. C. Axtell.

Spring and summer feeding of bees is so much easier done by feeding out of doors that we feed that way almost exclusively unless we know of a hive or more that is clear out, and then we give a comb of honey or one good feed in the hive at night. We keep our feeder at the east side of our honey-house, where the water runs off the house and keeps it full of fresh clean water whenever it rains, and this helps to keep water out for the bees, and at the same time keeps the feeder from drying up if we forget to keep water in it. Just now we are feeding only by putting the syrup in feeders in the evening, and on top of the feeder we set some black sections of honey-dew, as we don't care to feed much honey-dew by itself; then we cover over the feeder so as to shed off the rain should it come in the night. The bees work at the feed late in the evening and early in the morning, and have it all taken up before the neighbors' bees, two or three miles away, come around, and then they have the day to go to the woods and orchards.

WINTER FEEDING.

We always feed in the hives, as generally half or more of the colonies have enough. Often only a very few will need any, and the very best and cheapest feeder we can get hold of is a large tin pan set on the frames with a thin cloth like a flour sack put into the pan, and then filled up with syrup as thick as will dissolve sugar by stirring cold water into sugar and letting stand a few minutes to settle. We then pour off the clear liquid. We do not even heat the water any more, as it is so much less work. If we have any extracted honey we care to use, a little of that mixed with the winter feed, we think, makes it all the better, as it will keep it from candying in the combs; and yet we have not been able to observe any bad effects from feeding clear sugar. Bees winter all right upon granulated sugar if fed not later

than Sept. 15; yet I believe it pays better to feed in August, and let them seal their combs over thoroughly.

LATE FUSSING WITH BEES.

I am inclined to think, is very injurious; at any rate, our bees winter ever so much better, all things else being right, since we quit bothering their brood-nest in the fall. The honey may be taken off the top, and not seem to hurt them; but if they have a good queen, and get the hive well filled with honey before cold weather, and left alone without opening up the brood-nest, and are properly protected in winter, such colonies almost invariably come through safely.

UNITING WEAK COLONIES.

Doing this in the spring is not very satisfactory. We have about come to the conclusion that, if they can care for their queen, it is better to let them alone unless we have queenless colonies, and then they may be united to advantage with a weak one that has a queen. Feeding out of doors does more to build up weak colonies, and give them heart and health, than uniting. We crowd them down on to two or more combs, cover up warm, and let them alone.

TO MAKE BEES GENTLE TO HANDLE, WHEN WE HAVE TO HUNT OUT THE QUEEN TO CLIP HER WINGS.

When there is no honey coming in, there is nothing like feeding thin sugar syrup—merely water a little sweetened, and give them all they will take.

In all my foregoing remarks I would not have it understood that I believe in feeding sugar to have it stored in sections. I think that is wicked, and should be classed with other sins, such as stealing, etc.; but there is no need of getting a particle of sugar syrup in sections if we understand the habits of bees, and feed only when they would not store in sections, or when there are none on the hive. We can be honest or dishonest in every thing.

Our bees have wintered unusually well, having lost but one colony out of 115, and it was queenless, though there are quite a number

that are weak, but many very strong for this time of the year. Some of our neighbors report heavy losses; but I think it was where the bees were not properly prepared for winter. A person who does not understand bees, and will not take pains to learn their habits, it is just as well, and better, for his bees to be in good-sized box hives where their owner can not rob them very easily. They can get surplus by setting a box on top of the hive, with some white comb stuck into the box for starters, or they may stick comb or foundation into sections, and set into the box; but before setting on the box, large holes should first be made in the top of the hive—the larger the more readily will the bees go up to work.

A deep jar makes a good feeder of water. Put into it a handful of salt, and take a clean gunny sack and wet it and hang it in the jar, letting one end hang over on the outside. It acts as a syphon, and keeps wet, even on the outside, and no bees are drowned or chilled, as they are in all open water in cool weather. It being in a jar, the poultry can not get the salted water to drink. I don't know that it would hurt them, but I have been told it would.

I should have stated, that, when feeding bees for winter, the rest of the frames should be covered where the pan was set on except some little openings around the pan, and the cloth should reach over the side of the pan down to the frames; and over the pan lay a block to keep the quilt up out of the syrup, and cover all snug and warm. By feeding in a tin pan there is no leaking, as there almost always is with all wooden feeders.

THE HILL FEEDER.

If not taken off the hives as soon as empty, the bees seal up the little perforations or holes so the syrup can not get out quick enough, and so sours if filled the second time, unless they are heated and rubbed clean with cloth or paper, which takes time.

SPRAYING FRUIT-TREES WHILE IN BLOOM.

I think every bee-keeper should have an item put into his county or town paper, not to spray fruit-trees while in bloom. I feel certain our bees have been injured two different years in that way. Our bees took to dying off just about fruit-bloom; and a little after there would be but very few old bees left in the hives—lots of capped and hatching brood; and as I did not know of any of our neighbors spraying their fruit-trees I thought we killed them ourselves by spraying after the petals had fallen; but I have since learned that one of our neighbors did spray while in bloom. He said he did not know it would do harm. Spraying while fruit is in bloom has been talked and written about so much one would think every farmer would know better; and yet there are some who never read any but their local papers, and don't seem to know any better.

Roseville, Ill.

WINTER REPOSITORIES.

THE UPGROUND AND THE UNDERGROUND, AND THE ADVANTAGES OF EACH COMPARED, AND WHY THE FORMER IS PREFERRED: DOES THE MATTER OF MOISTURE HAVE ANY BEARING ON THE SUCCESS OF WINTERING? A VERY VALUABLE AND INTERESTING ARTICLE FROM THE MAN WITH THE REPUTATION OF ALWAYS WINTERING HIS BEES.

By H. R. Boardman.

Friend Boardman:—I shall probably lose 20 per cent of my bees in my home apiary, owing to the honey candying in the combs, as I think. You fellows who winter in regular bee-repositories will come through this hard winter with flying colors as usual, I suppose. Well, you have got the trade learned, and understand just the conditions needed for successful wintering indoors. If I had a perfect bee-cellar I should like to try wintering in that way, but am fearful I should not succeed in building a perfect one, nor succeed in controlling the temperature or the humidity. But now comes Doolittle (see GLEANINGS, page 59, current volume) with an article claiming that moisture does no harm in a bee-cellar providing the temperature does not run down too low. I had supposed that a bee-cellar should be dry; and as I have understood that yours was always dry I should like to know if you think this dryness essential to success, as I know that no one has had better success in wintering than yourself. Suppose you give us your views through GLEANINGS, on the proper conditions necessary for indoor wintering. CHALON FOWLS.

Oberlin, O., Mar. 25.

"Many seem to suppose that a bee-cellar in which bees are wintered should be dry in all its parts."—Doolittle in GLEANINGS, Jan. 15, page 59.

That hits me. I must own up I am one of those fellows. I have for many years had a very comfortable conviction that, in order to secure the best results in the bee-cellar, it should be dry in all its parts, and I have always tried to secure this condition as far as possible. That they do winter well in a moist or even wet repository is not new to me. But I am not quite ready to admit that the moisture contributes to the success of wintering.

Mr. Doolittle describes his cellar as not only moist but wet—actually wet and dripping, and filled with mold—sometimes great patches of mold on the walls as big as a hat-crown, and ready to seize upon the combs in the hives when not protected (see GLEANINGS for Feb. 15, 1894) and upon every thing where it could get a foothold. The glowing terms with which Mr. D. describes the nice condition of his bees in

this wet cellar is quite captivating, and might give others the bee-fever as well as himself; and I fear it might also mislead some to give the whole credit to the moisture. James Heddon reported a similar experience years ago, but not to advocate moisture as the most favorable condition, that I remember, but as an argument bearing upon the pollen theory.

The astonishing part to me is, that Mr. Doolittle goes on record as favoring such a condition—see *GLEANINGS*, 1894, Feb. 15. Mr. D.'s reports give him a good record for wintering his bees in this same moist cellar, except one winter when he reported a serious loss attributed by him to an oil-stove which he had placed in the cellar, to overcome the low temperature, I suppose. With his experience and sound judgment in such matters I feel sure that his good record will continue unbroken in wintering in this same cellar unless something unforeseen should turn up. But would it be safe to trust the novice in his place? I think not. Without the knowledge of the requirements of such a repository I think it would be unsafe and uncertain.

But what reason has Mr. D. for thinking that bees will winter better in a moist or wet atmosphere than a dry one? He probably has reasons, but he gives none except the excellent condition in which he describes his bees. Has he any assurance that they would not winter as well, or even better, if his cellar had been dry instead of wet? To those who contemplate building a wintering-repository, it is a question of first importance how to secure the most favorable conditions.

MY OWN EXPERIENCE.

Of the four wintering-repositories that I used for quite a number of years, I had but one that I considered perfect. This one is absolutely dry in every part, and mold rarely ever gets into it. It is in such perfect condition in this respect that combs and honey stored in it keep in good condition at all seasons. My section honey I have kept here for many years. This is my home bee-house, planned and built expressly for the purpose. My other bee-repositories were improvised. About 200 colonies I consider the utmost capacity of my home bee-house; 150 to 160 is about the average number that I have wintered in it for years. This gives 75 to 80 colonies in each of two rooms, making what I consider a well-balanced proportion of colonies to the size of the rooms, which is of much importance. Now, I am sure that this bee-house could not winter better with a moist atmosphere instead of a dry one. Every colony put into it in November in normal condition I expect to come out in the spring in just as good condition as when put in. Even light nuclei winter just as well as strong colonies. I attribute the perfect wintering qualities of this bee-house largely to its dryness and wholesome sanitary conditions. It is not entirely secure

against outside changes of temperature, but varies considerably. It is sufficiently protected to avoid sudden changes and extremes, and is perfectly safe for a short time between the extremes of 35° and 60°. Uniformity I do not consider important. The regulation 45° is, no doubt, about right. A high temperature is much safer than a low one in any bee-repository. Artificial heat I know to be a good thing; and in the building of a bee-house I would advocate some provision for it. The absence of mold may be partly due to the fumigating with sulphur which I frequently give the rooms for the benefit of the honey and combs stored in them during the warm season. Two of the four repositories mentioned were very good cellars under dwelling-houses. These were walled up in the usual way with stone. In each of these I made a room of the size which I thought I would need for my bees by means of a partition of matched ceiling. When I had them finished I thought they would be good wintering-repositories for the bees. But I have never been able to winter in them as perfectly as in the home bee-house. Although not as wet as Mr. D. describes his to be, they would always accumulate some moisture; and the combs not protected by the bees would be more or less damaged by mold and fermentation. Light colonies were especially exposed, and the first to suffer. All unsealed stores, especially the pollen, would be affected.

I regard the wintering of the stores in good condition as decidedly important; for upon their condition depends the future prosperity of the colony. There is no question about their wintering best in a dry place. I found these cellars too cold. They were affected too much by outside temperature—a fault I had no means of correcting, as I had no means of raising the temperature during a long steady cold spell, and this I think is the prevailing fault of such repositories. They were by no means cold cellars, as they were frost-proof, and sufficiently warm for vegetables, but they were cold bee-repositories. If such a cellar has to be used it is best to put in as many colonies as can be safely controlled during the warm weather in early spring before it is time to set them out, for they help to keep up the temperature during a cold spell. If these cellars had been as dry as my home bee-house, the low temperature would not have been at all serious; or with artificial heat the fault might have been easily corrected. Look out for cold if the wintering repository is damp.

WHAT MAKES THE MOISTURE IN THE BEE-CELLAR?

The walls are cold. The bees generate heat, which warms the air about them. This moves out to the walls and cold corners, and deposits the moisture with which it is loaded, by condensation, where it will remain if there are no means of absorbing it or evaporating it by ven-

tilation. Of course, so long as the bees keep up the proper balance of heat, no moisture can be condensed upon the hives or combs; but upon this balance hinges life or death to the bees.

Cold and moisture are destructive to the bees when they meet as allies; but so long as they do not come together they are comparatively safe. Bees will endure severe cold if dry. They will also withstand much moisture in a high temperature.

If you decide that you want to make your bee-house so that it will be dry, make the walls of material that will absorb moisture instead of condensing it. Imitate the chaff hive. I would suggest, as an improvement to walled repositories that condense moisture, an inside lining of matched ceiling, with an air-space between it and the wall. This would prevent the condensing of the moisture without interfering with the requirements necessary for wintering. I am quite sure that this would improve the sanitary condition of such damp repositories.

A great many bee-keepers are situated in a level country where they could not build like Mr. D., by burrowing into the side of a hill, if they wished to; but they must build wholly above ground. This requires an entirely different structure—one with double walls packed with some kind of absorbing material like sawdust, or with dead-air spaces.

Then I would say, as regards the conditions desirable, according to my experience in a bee-repository, I would have it frost-proof and dry; dark when required. That it is necessary to have a bee-repository always shut up from the light is a very great error. If other conditions are favorable, the light does not disturb the bees in the least. When they are inclined to fly out of the hive at a low temperature it is an indication that something is wrong. With a high temperature toward spring it is then necessary that the bee-room be dark; but the fore part of the winter it is not important. I leave my bee-house doors open after the bees are put in until the weather is quite cold. The bees remain quiet.

A valuable feature in a bee-house is an extra room adjoining the bee-repository, which may be used as an air-chamber to furnish air to regulate the temperature to some extent. It is the sub-earth theory realized. If the bee-room is small and well filled it will be kept warm by the bees during the coldest part of the winter; and as the temperature rises in the bee-room at the approach of warm weather or during a warm spell, more room can be given by opening into this room as required. In this room I would also have a stove to furnish artificial heat. After years of experience I would not think of building a bee-house without providing the means of using artificial heat when needed. There are times when an hour spent

in warming up the bees just a few degrees would improve their condition materially.

I have been delaying this article a few days in order that I might read it over again to see how it would sound after I had set out my bees. I have to-day, April 5, set out from my home bee-house, 178 colonies without the loss of one from any cause; although quite a number were small and light in the fall, they all, so far as I can see, are in as perfect condition as when they were set in last November. They seemed to start in right where they left off last fall. It is not enough that bees come through the winter alive. They may do so, and yet come far short of being well wintered.

East Townsend, O., Apr. 5.

[A few days ago we received a card from Dr. Miller, calling our attention to a few paragraphs in Gravenhorst's journal, *Deutsche Illustrierte Bienenzeitung*, and advising us to translate and print them. Fortunately, as it turned out, we had no particular use for them till the reception of the article above, from Mr. Boardman; and now, like "the stone which the builders refused," it has a marked bearing on the question, with a decided inclination in the direction of Borodino, N. Y. Mr. Schönfeld is held in the highest esteem by the best bee-men of Germany (or Europe for that matter), and his indorsement of Mr. Czeselski's views seems to be very enthusiastic. We give it here for what it is worth; and we have no doubt the experiments were performed with that great care which is characteristic of the Germans.—W. P. R.]

Mr. Czeselski says:

Bees use water in winter. They get this water from uncapped honey, which absorbs it from the surrounding moist air. There is always found, in winter, in the upper part of a bee-cluster, a greater or less number of uncapped honey-cells, as the bees always uncap them in advance, without consuming the contents. These uncapped cells are designed to absorb atmospheric moisture. The more favorable the circumstances may be for the honey to absorb moisture, the smaller will be the number of cells uncapped. In clumps of bees, and in their immediate vicinity, where a temperature of only from 52 to 54 F. prevails, brood-rearing can not go on. The air which is breathed out by the bees, which is already somewhat moist, receives in addition, by the condensation of the moisture in the cold outer air, a considerable amount of wetness. Now if, while condensed, it comes in contact with an absorbent body, it is clear that the latter will take from the former a certain amount of moisture, or even make it so dry that, when it impinges against the cold walls of the hive, it can give off but little more dampness. A colony under such conditions will winter well. Still, if the brood-nest is too small, and crowded with bees, and the entrance not broad and high enough, or if the colony stands in a warm place, the temperature will rise, and hence the honey can not absorb water enough from the expired saturated air to meet the requirements of the bees. They will suffer from thirst, and winter badly. If the air contains too little moisture, the honey itself loses a part of its own. It happens in summer that the bees try by fanning to introduce large amounts of dry air into their hives, in order to ripen the green honey."

[Mr. Schönfeld continues:]

That is a beautiful and intelligible view of bee-life, which will be hailed with joy. It is the fruit of a searching and comprehensive investigation into the economy of the hive, as well as a clear insight into physical laws bearing on the case, and an exact and scientific examination, which the doctor has given us. From the most careful experiments,

we learn: Three grains of uncapped honey will, in 24 hours, in a temperature of 76°, absorb only .584 grains of water on an average; while three grains of the same honey, impregnated with the same quantity of water, but which, during the experiment, has cooled down to 56°, will, in the same space of time, absorb 1.527 grains of water. Other experiments showed that the three grains of honey, in 24 hours, at a temperature of 76°, took up, on an average, 1.032 grains of water, and at 50° absorbed 2.7 grains, and in one case even 3.034 grains. In the dry air of a room, on the other hand, having a temperature of 61°, three grains of honey lost only .04 of a grain of water. In three experiments, made directly in a cluster of bees, at a constant temperature of 50°, five grains of honey received on an average 3.068 grains of water. No experienced observer or student of the universal laws of nature can doubt the results of these experiments. We find it perfectly easy to comprehend that ripe honey, containing only 20 per cent of water, which the bees bring in as nectar containing 80 per cent, does, by means of energetic fanning, lose 60 per cent of its moisture; and that it attracts back to itself its lost property, water, as soon as the bees uncapped the cells. It is the nature of honey, when five grains of it contain only one part of water to five of solid part, to absorb, on an average, 3.068 grains of water; for it will not take back more water than it originally held as nectar, as nectar is four-fifths water.

[As our readers know, I have visited Mr. Boardman's home a number of times, and illustrated and described his favorite winter repository at his home apiary a few years ago. As it may not be convenient to refer to this I reproduce one of the engravings we then made.

It shows the outside of the repository. It is a plain double-walled building, divided off into three rooms—two large rooms, one at each end, and one smaller one for entryway in the center. The whole structure is 12x50 feet, with walls 14 inches thick, and packed.

R. L. Taylor's experiments last winter, as reported in our last issue, seem to show that moisture, or even an excessive amount of moisture, does not have a deleterious effect on the wintering of bees; but Mr. Taylor seemed to regard as of prime importance an even temperature, and Doolittle seemed to be of the same opinion. Observe that Mr. Boardman thinks a dry repository important, but does not consider the matter of exact regulation of temperature necessary. If I am correct, Mr. Boardman winters right along, year after year, in this repository, with absolutely no loss. If the proof of the pudding is in the eating, then Mr. B. seems to be nearer the truth. Or perhaps we can put it this way: If the cellar is moist, we must have an even temperature; if it is an up-ground repository, and dry, even temperature is not necessary. This will harmonize the opin-

ions of Doolittle, Taylor, and Schönfeld, on the one side, and Boardman on the other.

With regard to artificial heat at certain times in winter repositories, Dr. Miller has seemed to stand almost alone in its advocacy. But now comes Boardman supporting it, and, for aught I know, he may have been a practitioner of the idea as long as or longer than Dr. Miller.—Ed.]

B. TAYLOR'S LATEST HIVE

LARGE HIVES HAVE TOO MUCH ROOM BELOW, AND CONSEQUENTLY LESS SURPLUS; THE FORCE OF DADANT'S ARGUMENT FOR LARGE HIVES LOST, AND WHY.

By B. Taylor.

Editor Gleanings:—I see you still wish beekeepers to give their ideas in regard to small or large hives. I have tested more styles and sizes of hives in my 45 years of apiarian experience than any other bee-keeper I know of. To me it is a great pleasure to realize that I know a thing in counter-distinction to merely believing it, for belief may be founded on either truth or error, and we must not forget that error is no less harmful because honestly entertained. "Prove all things, hold fast to that which is good."

Many years ago I made four large hives that contained 4000 cubic inches each. I expected to get large yields of comb honey from them. I reasoned that, by clover time, these large hives would contain gigantic colonies of bees, and would not be likely to swarm. Well, I believe they never did swarm during the three or four seasons I used them; but the giant swarms were never ready at the right time when the white-honey harvest came. Each season these big hives would contain no more bees than hives of 1200 inches of comb capacity, and I never got any surplus from them worth mentioning, and what they did give was always dark fall honey. You see, they had ample room in those big brood-chambers, to store all the white honey they did not use in raising the great colonies of bees that those hives always contained at the end of the season. This immense force would, before spring, consume nearly all of the large store of honey which those hives always contained at the commencement of winter; but these old bees would pretty much all be dead the following spring before a new force of young bees could be raised to take the field; and they would have to build up again from about the same condition as swarms in small hives, with this disadvantage—that the large hives did not utilize the heat of the colony nearly as well as the smaller ones in the cool weather of spring.

A year or two ago we resolved to discontinue further general experiments in testing hives. We resolved to select from the fruits of our experiments that hive and system that actual experience had taught us would give the very best results in white surplus honey, either comb

or extracted, with the least amount of work, and be good at the same time for wintering and breeding up colonies in the spring. And now, friend Root, to describe just how these hives are constructed, and the reasons for them, and the system of using them, will give a clearer explanation of my present understanding of the *best* hive than any other words could give.

The new hives are 16 inches square, outside measure; $14\frac{1}{4}$ inside, and the bodies are 9 in. deep. The frames are $13\frac{1}{2}$ long by $8\frac{3}{4}$ deep. Each frame contains 100 inches of comb surface, and we use 10 of them in a hive. Those hives then contain 1000 cubic inches of comb surface. This is, then, according to the common popular understanding, a small hive. And now for the system of using them. We will hive new swarms in one of those hives on eight combs, two dummies being used in place of the outside combs. Each hive will be given all supers of sections filled with either finished combs or foundation, or part of each that they can use. At the end of the white-honey season (basswood here) we will remove the surplus cases, take out the two dummies, return the combs, place a queen-excluding honey-board on top, and on this another hive, either a new one filled with foundation or one filled with bees and brood from which a swarm has previously issued. If the last is used I will see that the queen from the new swarm is removed, and the old swarm with its young queen put under. I want no brood raised further in the top hive. As the brood in the top hive hatches, the combs will be filled with fall honey. If the flow should be good I will add other hives as needed until the end of the season. At the end of the honey season I will take off all hives above the queen-excluder, having, a day or two previously, put an escape-board under them and run all the bees into the parent hive below, which hive will be examined as to stores, and, if lacking, an abundance will be given from the filled combs from the top hives taken away. We will winter the colony in a single hive. They are easier to handle, take less room in the cellar, and we *know* that, with us, a small hive with a good colony of young bees, and plenty of stores, is in the best possible condition for cellar wintering.

In the spring we will remove the colonies to the summer stands. These stands will have room for two colonies each, but we will have only one colony to the stand until swarming-time; but previously we shall have added to each colony a second hive taken from those used on top last fall, and more or less filled with honey; but we shall not add the second hive until the first one is well filled with brood, as they will breed up much better in the small single hive early in the cool weather of spring.

In this system each colony will have two hives at swarming-time. We will give each

colony, run for comb honey, cases of sections early, for we do not care whether they swarm early or late. We will keep them storing surplus without swarming at all, as long as plenty of room will do it; but we will use no *force* measures to prevent swarming; for, after the most searching effort in that direction, we are now thoroughly *convinced* that it can not be *profitably* done. When the swarm does finally come (if it does), we will hive it in a hive contracted to eight frames or less; remove all surplus cases from the old to the new swarm; set it on the old stand, turn the entrance of the parent colony in an opposite direction on the vacant space on the same stand to be relinquished, and the two colonies will be united again after the white honey-flow as before.

In working for extracted we will simply give each colony all the hives they will fill; and in case they swarm we will treat them exactly as for comb honey. If, after we have supplied all our colonies, fall and spring, with all the combs of honey they can use, if any remain we will extract them; but we will use every pound of dark for winter stores and brood-raising; for by this management we can and will secure nearly the entire white-honey crop for surplus.

Now, Mr. Editor, I have written not only about small hives but how to use them. Many bee-keepers try small hives. They use them exactly as they would large ones. They do not find small hives profitable, and argue against them. I have great respect for the Dadants as bee-keepers, and their argument for large hives had almost persuaded me; but now comes Mr. Dadant, in the *American Bee Journal* of May 9, and states that his average yield of extracted honey from colonies in his big hives is *only fifty pounds*, and that his greatest yield was only 150 lbs. per colony. Friend Dadant, you have, to me at least, given the whole argument for your large combs and brood-chambers away. A small comb, all will agree, can be handled more easily and pleasantly than large ones, and small hives the same. You may say I have more combs to handle in my two sets that I use at times; but I tell you that, with my wired end-frame, with which no followers, wedges, thumb screws, or other traps are used, but where each comb can be taken from any part of the brood-chamber with the naked fingers, and returned to their exact place without the use of our eyes at all, the handling of frames becomes a pleasure and pastime. As for crops, we have always worked for comb honey, and have for 20 years regarded less than 100 lbs. per colony, spring count, as partial failure. We have in a good year secured 143 lbs. per colony from a whole apiary, and 90 per cent of it white honey. The seasons of 1893 and 1894 were regarded as bad ones here, and yet we harvested more fine comb honey each of those seasons than Mr. Dadant says he gets in extracted in average good years. No, friend

Dadant, you may go ahead with your big hives. I now *refuse* to be "persuaded."

Now, friend Root, in praising my own special hive I do not mean to condemn other small hives (or large ones either). I have no doubt your eight-frame Dovetailed hive can be used in the system I practice, and have explained in this article, to good advantage.

Forestville, Minn., May 17.

TWO EIGHT FRAMES, ONE TOP OF THE OTHER,
NOT AS GOOD AS THE JUMBO HIVE.

Editor Gleanings:—You ask friend Nash, on p. 349, if he ever tried two eight-frames, one on top of the other. I will say that I have tried them, also the ten-frame two and three stories high, and they do not give as good results. Why? Because there isn't sufficient cap room. You can get strong colonies in the eight or ten frame two stories, but they are not in convenient form for sections. You see, when you have the sixteen frames in one hive you can put on 48 sections, and the hive is not yet as tall as it is wide or long; you can put on another tier of 48 sections, and it is not yet as high as it is wide or long. All bee-men acknowledge that the proper form of a hive is square, as nearly as may be. When the third tier of sections is added it is then nearly square.

How do you suppose the eight-frame two-story hive would appear with this number of sections on? Rather out of proportion, I think; don't you?

I find that I can conform to the principles of honey-production, as laid down by Heddon or Honey Producer, better with my Jumbo hive than with any other hive I have used, except his third principle, which cuts no figure in this management, as the bees seem to fill the outside sections just as well in the sixteen-frame as in the eight-frame hive.

I was extracting from the Jumbo hive May 2d. One of them contained seven frames of sealed brood. May 4 I transferred some from ten-frame hives into the Jumbos; three and four frames of brood was all they had, and they were packed in chaff, sides and top. All the protection the Jumbo hives had was the upper story filled with chaff. The eight-frame hives are none of them ready to transfer yet.

Raspberry will soon be in bloom. The bees wintered in the Jumbo hive will be in fine shape to store it while the eights and tens will be building up. N. E. DOANE.

Breckenridge, Mich.

Friend Root:—I have watched with great interest the discussion relating to large and small hives, and trust the same will be continued until all the light possible has been thrown on the subject. There are a few individual bee-keepers in this country who think they know it all; but they are a disagreeable class of men to deal

with. The great mass of your readers do not belong to that class, but are willing and anxious to learn while they live. If my apiary were situated at a distance from the river-bottoms, where I could not have early and late pollen and honey, I think it would be an advantage to me to use the ten-frame hive in preference to the eight-frame. If I ever increase my bee-business I think I will try fifty ten-frame hives, and institute some comparisons; then if I decide that I do not want them I can sell them to some fellow on the other side of the fence, or send them to Richland Co., Wis., to be used for *Hatch*-ing purposes.

The strongest colony now in my apiary was wintered out of doors on two hive-bodies of 8 L. frames, each packed in planer-shavings. On the 3d of May I noticed about one peck of bees hanging out at the entrance. I examined them and found much brood in both stories, and queen-cells started preparatory to swarming. I gave them a third set of frames, which they at once occupied, and now (May 13th) I find the preparations for swarming have disappeared; and truly there is no occasion for it, as there is but little prospect here for a honey crop before basswood.

But here is the point I wish to make: If the experience of the past winter holds good, there are other colonies in the yard that would now be considered rather weak, but at the close of the season's work I shall find that their honey-record is as good as or better than that of the other. If a queen produces a large amount of brood very early in the season, and the honey season is long, as it usually is here, she will be very likely to do less during the middle or latter part of the season than some queens that do not get down to business in egg-laying so early.

Browntown, Wis.

HARRY LATHROP.

FOUL-BROOD LAW IN WISCONSIN

INDEFINITELY POSTPONED; AN APPEAL TO THE
BEE-KEEPERS OF THAT STATE.

By N. E. France.

I am surprised that the bee-keepers are so indifferent to one of the vital points in bee culture. Often have I called upon bee-keepers of our State, and explained to them the nature of foul brood, contagious and fatal; and unless something is done to stop the spread, the future outlook for Wisconsin as one of the best honey States is very alarming. Many times I have been asked, "How near is foul brood to their bees?"—as if a few miles insured their safety! With the present demand for queens and honey, I have plenty of cases reported where foul brood has appeared from some supplies bought 2000 miles away. We have never had a case of foul brood, and don't want to. I have spoken on this subject in conventions in many towns of Southwest Wisconsin. Last November, at Montfort, the Southwestern Wisconsin Bee-

keepers' Convention voted their president be delegated to draft a bill for the suppression of foul brood in Wisconsin, and attend the State convention in February, and get them to assist in having the legislature act on the bill. I appeared before said society, which voted F. Wilcox, their president, to act as State delegate. We in committee carefully reviewed each section of the bill, and reported what we considered a model, much in form like the Canada foul-brood law, which is doing so much good. That evening my assemblyman reported Bill 300 A. for consideration, which was referred to the Committee on Agriculture. About two weeks later I was telegraphed to appear before said committee in defense of the bill. I took the next morning train, and at 1:30 P.M. appeared as directed. Said committee reported the bill was worthy of consideration; but as it provided for an appropriation to defray expenses of a State Inspector, they would recommend the bill for indefinite postponement. As soon as this report reached me, I learned by several assemblymen, that, if the bee-keepers would write them, urging the passage of the bill, it would have quite an effect. I wrote 65 postal-card requests to bee-men, asking them to plead for their interests. Had they all responded with the earnestness of F. Wilcox, H. Lathrop, and F. Murray, Wisconsin would have had a foul-brood law.

I set a date for them to reply. The same date I again appeared before another State claim committee, with only a small handful of letters for support. As a last resort I presented this committee a bill the same as before, except that no State money was asked, but a two-cent-per-swarm tax on all colonies of bees, to defray expenses, was added. As this made the bill self-supporting, they voted to recommend its passage. Next day it was presented to the Senate, and returned for indefinite postponement.

Now, Wisconsin brothers in bee culture, I have been at \$25.00 personal expense, and wish to say that, if you had done your part, we should have had a law for our defense. Am I going to give it up? Not until we have a State foul-brood law. I know the ground we have to go over, and will for the next two years try to get our bee-keepers interested. If at first you don't succeed, try, try again.

Platteville, Wis., May 6.

BEFORE THE WESTERN CLASSIFICATION COMMITTEE.

FREIGHT RATES ON EXTRACTED HONEY IN BULK MATERIALLY REDUCED.

By Herman F. Moore.

Mr. Root :— Dr. C. C. Miller has just left my office with Mr. Geo. W. York, and will stay one night at Ravenswood with him. The doctor stayed at my home last night. He says he has

often been asked to pronounce a benediction, but answered that he was not a minister. But I tell you it is a benediction to have Dr. M. for a guest; and if he did not preach to us— why, I never heard preaching. Mrs. Moore and myself were charmed by the doctor's visit. He sang for us in his own inimitable style, and played an accompaniment on the piano.

We had 45 minutes before the full committee. It consisted of about sixty men of all ages, from the youth of 25 years to the gray-headed veteran railroader, seated at a long table in a room 75 feet in length.

Dr. Miller called attention to the fact that the bee-business is a great and growing industry; that it needs encouragement from the railroads to develop into one of the greatest interests in the land. He said, by way of parenthesis, that he was there in the interest of the roads; that if they'd give us lower rates we'd give them more business. He mentioned the fact that one supply-firm had shipped seven carloads to western points in one month (The A. I. Root Co.); also that fourteen carloads of honey was shipped from Arizona in 1894 to one firm in Chicago (R. A. Burnett & Co.).

Nine petitions were presented to the Western Classification Committee by the chairman of the committee appointed by the North American Bee-keepers' Association at its convention at St. Joseph (Dr. C. C. Miller, of Marengo, Ill.). Petitions on four of these same articles were presented by The A. I. Root Co., of Medina, O.

Bee-hives in the flat was first on the list. Through the kindness of T. G. Newman, sample packages of stuff were on hand to show the committee. Mr. York, editor and publisher of the *American Bee Journal*, assisted the writer in elevating the samples in view of the committee. Attention was called to the fact that bee-hives in the flat (K. D.) have no greater value than average lumber shipments, and that the Trans-continental Committee had already rated them with box stuff at a very low rate.

Samples of the Crane and Clark smokers were next shown to the committee. They took great interest in these, and one or two amused themselves in a quiet way by aiming the current of air at a fellow-committeeman's face.

Samples of honey-box lumber were then presented, and the uses explained. Just then a young man asked how long a bee lives, to the great amusement of the others. Dr. Miller said it depended on what kind of a bee he meant. Another committeeman put in, "A bumble-bee," and the whole committee of railroad-men burst out laughing, like a lot of schoolboys.

The writer believes that whatever reduction is obtained will be more the result of Dr. Miller's jokes, and R. A. Burnett's case of honey, which he presented to the committee, not for publication, but merely as an evidence of good faith, than to any of the solid arguments advanced in the course of the conference.

In answer to the question, Dr. Miller said that ages vary greatly, and explained the matter at length as bee-keepers understand it.

Then said Dr. Miller, "I am going to tell the biggest whopper yet. Our queens lay as high as three thousand eggs in a single day;" and some gentleman remarked, "That is the reason the bees live so short a time."

The honey-extractor crated was then exhibited, upright and lying on its side, so as to give the committee a good idea of the structure of the same. The committee was asked to classify these, as there is at present no classification of them in the Western.

Honey in comb being the next petition, a section of comb honey was handed about, and the gentlemen began to sample it with their fingers.

Dr. Miller explained at length to the committee that we as bee-keepers want the glass in sight; that we have no fear of breaking the glass, but the honey inside, owing to ignorance of the nature of the contents. A large crate to hold a dozen 12-lb. cases was shown, and our method of packing the same explained. We hope to get a second-class rating for comb honey packed in this manner. There is no doubt that this is the ideal way to pack comb honey for shipment in less than carloads. The writer received one shipment of over 1000 lbs., without any breaking, the past season.

Friend York kindly furnished a Muth jar of fine extracted honey, which was passed around, and the gentlemen invited to partake of the same. R. A. Burnett suggested that it was not to use on the hair.

A good point Dr. Miller made was that the railway companies, in rating extracted honey, valued it equal to comb honey, when, as a matter of fact, the average extracted honey has about the same value as good syrup, and no greater risk in handling. The doctor explained why this is so.

The chairman of the railway company asked the value of comb honey. He also asked the value of beeswax and of comb foundation.

One reason why the companies rate these things high is, that they look at the value compared with the bulk and weight. Four things they consider in classing our products—weight, value, bulk, and risk of injury in shipping, to the goods shipped, or to the other goods in the same car.

Another point against the high rating of honey is the fact that all shipments are actually at owner's risk of leakage or breakage, as an owner collecting for loss by transportation is almost unheard of.

In regard to beeswax, we informed the committee that, by high rates, they prevent much wax from being shipped and comb foundation returned—a double shipment and double transportation charges for the roads.

Bees in hives less than carloads are refused by the roads at present. Dr. Miller told them that,

under such circumstances, a bee-keeper desiring new stock pays Uncle Sam two cents to carry a queen-bee by mail, when often full colonies would be shipped if taken at a reasonable rate in less than carloads.

The railroad committee on classification rendered great courtesy and lots of interest in all the remarks made by the committee of bee-keepers. Too much credit can not be given these gentlemen for the kind manner in which they treated the committee.

Naturally your committee felt some timidity in appearing before these railroad magnates who hold, as it were, the destiny of half a continent in their hands. One of our number said we might be in the predicament of the gentleman who went to the general passenger agent to get a pass. After the applicant had told his story, the G. P. A. remarked with a drawl, "Well, yes; I can give you a pass or I can give you the money to buy a ticket."

We shall be on the anxious-seat for a few days until the rulings of the committee on our petitions are made known."

In the meantime a step in advance has been taken. We have published the fact that we are alive, and doing business at the old stand. This committee, and through them the railroads they represent, will in the future have more respect for our honorable pursuit. Our claims for damages will receive more respectful attention, and good must result to the craft at large from this meeting.

Later.—I have just seen Mr. J. T. Ripley, the chairman of the Western Classification Committee, and he informed me as to the result of our petitions as follows:

Bee-hives in flat—petition denied.

Honey-box lumber, referred to the Western Freight Association, John W. Midgley, chairman, 7th floor, Rookery.

Bee-smokers—petition denied.

Honey or wax extractors, crated or boxed—petition denied.

Honey in comb, glass fully protected—petition denied.

Glass fronts not protected, future rating first class.

Extracted honey in barrels, kegs, or tin cans boxed, future rating fourth class.

Beeswax—petition denied.

Comb foundation—petition denied.

Bees in hives—petition denied.

In regard to bee-hives "K. D.," which should have been referred, to be consistent, along with "honey-box lumber" to the Western Freight Association, the writer was informed by Mr. Ripley, the chairman, that he might get "bee-hives K. D." referred also.

Mr. Ripley very kindly accompanied the writer to a number of railroad freight offices, for this purpose.

The next meeting of the Western Freight Association occurs in May, and it is too late now

to get on the docket the petitions referred to. The next meeting after May will occur in June, if I am correct, and then our petitions will be taken up. It will be best to get our material in shape to present to them in the best possible manner as they make the final ruling.

Chicago, Ill.

FEEDING.

THE OLD STYLE OF MILLER FEEDER PREFERRED, AND WHY.

By Emma Wilson.

The first thing we did after taking the bees out of the cellar this spring was to weigh each hive; and any colony that weighed less than 38 lbs. was given a frame of honey. As soon as the bees were hauled to the out-apiaries, we commenced putting on feeders. Into each feeder we put 5 lbs. of dry granulated sugar. Then we made a little hollow, right in the center of the sugar, and poured in about a pint of water, and so on till all the feeders were treated alike. After they had stood half an hour or longer, we added three quarts of water to each feeder.

The object of putting the small amount of one pint of water into each feeder at first was to let the sugar have time to dissolve, so that the first that passed through might be sweet. If the whole amount of water is put in at one time it will pass through so rapidly that it will be very little sweetened, and the bees will not take it readily. It pays to look after all these little items, even if it takes a little more time.

When the Miller feeder was improved upon, Dr. Miller was very much pleased with the improvement, and we made 25 of the new kind, intending to discard the old ones. But after a thorough trial we liked the old ones a good deal better. In the first place, if there's any leakage it is inside the hive, and that is quite a point. It is more convenient to have one large compartment rather than two smaller ones. The one point that we thought would be of so much value, and prove so much superior to the old one, that of the passageway directly over the brood-nest instead of at the sides, in actual practice has not proven to be so. Just why, I can not tell. It really seems as if it ought to be; but our old feeders are the ones that are emptied first, and, as a consequence, the new feeders are the ones that we use last.

Many of our feeders have been on for more than three weeks, with only 5 lbs. of sugar in them, and are not empty yet at the present date, May 4. The very strong colonies do pretty good work at emptying, while those of medium strength empty very slowly, and the weak ones are almost a total failure. Last fall our feeders, with 15 lbs. of sugar, were often emptied in a day or two, while this spring the strongest colonies are several days in taking 5 lbs. Fall and spring feeding are two entirely different

things. Of course, we should expect the strong colonies of fall to work faster than the weaker colonies of spring; but there seems to be more difference than can be accounted for in that way. Perhaps it may be accounted for in this way: In the spring there is so much brood to care for in proportion to the number of bees that few bees can be spared for the feeder, while in the fall there is little or no brood.

I notice that, where there was a leakage from the new feeders on the outside, the bees took the feed eagerly, seemingly more willing to work outside than inside the hive; and, strange to say, the bees work along busily day after day on this leakage without any indications of robbing.

We had, however, two colonies robbed this spring, not where there was any leakage, but the robbers went in at the entrance, which was not large, up through the hive, and emptied the feeder, and left no honey in the combs. The curious thing about it was they did not destroy the colony.

All things considered, never a feeder would we put on in the spring if we had only enough frames of honey to feed with. We planned for this last spring; but when the season is a total failure, and the bees can not gather enough to keep them over winter, where are the frames of honey for spring feeding to come from? Might it not have been a good thing if we had had the bees fill some extra combs of sugar syrup last fall?

Marengo, Ill., May 4.

REMARKABLE RIFLE-SHOOTING.

Yes, Buckskin Charley beats my record on deer-shooting; but I think he had greatly the advantage over me, as his record was made at a time when game was very plentiful, and not wild. Although he used a rifle he "still hunted," which allowed him every advantage, while here at this late day deer are so scarce a man could walk for a week, and it would be an accident if he ever saw one. Deer are now found only in the wooded districts of East Texas, and we use hounds to find them; so we hunt on horseback, and run for a chance to shoot. I have killed many a deer while my horse was running at full speed, as well as the deer. This makes hard shooting—quite a difference from being on foot. A few years back I was quite handy with a rifle. I used a 22-caliber Winchester rifle, but my shooting was confined to target practice—at flying targets too. The best score I ever made, I broke 38 balls thrown by hand into the air, out of 40 shots. I have cracked walnuts, peachstones, and pecans, thrown into the air—yes, nickels and dimes. This requires very accurate shooting, as a 22 ball is very small.

J. D. GIVENS.

Lisbon, Texas.

RAMBLE 133.

IN THE MENDOCINO MOUNTAINS.

By Rambler.

At Lakeport we were advised to leave the county by way of Scott's Valley and the Blue Lakes. We accepted the advice, and through the valley we go. Here we find again a general farming community. Many hop-fields abound; and as it was nearing the time of gathering, a large band of Indians had arrived from some not remote reservation, and were camped on the sandy shore of the river, and their camp made a lively and picturesque scene.

Blue Lakes were rightly named. The waters are clear, and of a bluish cast. Three little

in Mendocino Co., there was a fine running stream full of fish; rabbits in the brush, quail in the grass, and deer on the mountain; and from thence it was hurrah for the game. It was after dark when we found a good camping-place; but darkness had to flee when Bro. Pryal started a camp-fire. Old floodwood was piled up all along the stream; and, what a roaring camp-fire we enjoyed! Plans were laid for the morrow, and we could already see fish and game piled up all around our camp.

Before the gray of dawn appeared, Wilder was off with his rifle in quest of deer. Pryal and I fished. After about two hours angling I caught one 4-oz. trout; returned to camp; dressed, cooked, and ate my fish. In about an hour Pryal returned with one little fish and a long record of bites. His fish was also cooked and eaten, without much comment. I believe I suggested that we had forgotten to catch a fish for Wilder, whereupon Pryal thought we'd have to serve him with the bites.

Wilder soon appeared on the mesa beyond

MOUNTAINEERS.

lakes were linked together like a chain, and set like so many gems in the folds of the mountains. Bold bluffs, placid waters, mountains shading off into the smoky distance, gave us views pleasing to look upon.

Of course, Mr. Pryal had to clamber out on a log to fish. Result, some splendid—bites! We had set our minds to camp at the last of these lakes; but an honest-looking freighter we met told us that, a few miles further down, just over

our camp. Said I, "Wilder has shot a deer."

"What makes you think so?" said Pryal.

"Why, just see how he grinds his heels into the ground; and see how rapidly he walks."

So it proved. Susan B. was hitched to the cart, and away they trotted up the canyon. A fine buck, "mit horns so vide," was soon dangling to a limb in camp, and that day was devoted to eating venison, and jerking for future use the portion we could not eat.

The next day being Sunday, we all rested in camp. Our neighbor half a mile away had a fine herd of pigs that gave us some trouble; but Jack was equal to the occasion, and kept them at a safe distance. This neighbor said that it was no uncommon thing to find bee-trees in these woods; and, though he was not a bee-keeper, and no one kept bees near him, his observation enabled him to confirm the previous reports in relation to the great prevalence of honey-dew. At certain seasons the trees, shrubs, and grass were covered with it. Our experience with insects, however, was in the yellow-jacket line. These determined fellows were hungry for venison; and our slashed meat, as it hung in the sun to dry, began to disappear. We were told afterward by hunters, that, if unmolested, they would spoil and get away with a large amount of meat. We saved our meat, however, and consoled ourselves that, though there were many bees working on blossoms near by, they did not devour our meat. Half the ills that are laid to the honest bee might be cast upon the troublesome hornet.

After the two days' rest and such an abundance of venison, we made a lively gait to Ukiah, the county-seat of Mendocino Co. After a very brief halt we commenced a drive with Eur-ka, in Humboldt Co., as our objective point, or about 140 miles of mountain roads, streams, and forests. The towns began to dwindle in size, and the distance between them began to lengthen. The saloon seemed to be the main business center of these towns, and the saloon-keeper seemed to be a very public-

taking a nip. In Caliente the enterprising saloon-keeper, in addition to the watering-place, provided an awning, in the shade of which the team could rest while the driver

A CHANCE FOR PRACTICE NOT TO BE MISSED.

was taking another nip. We watered our horses, but eschewed the nips. Here we began to meet again those many-teamed wagons hauling immense loads of merchandise into the remote mountain regions; and the jangling bells, upon the leading horses, made merry chimes in the air. Our days were passed in climbing and descending grades—rough grades, serpentine grades, forest grades, and but a small mileage of level grades.

The native mountaineer men and women were usually mounted upon horse or mule, the ever-present rifle across the pommel of the saddle, and the long picket-rope coiled in a convenient place. If we desired information about the roads, the woman always did the talking. The man with her usually had his mouth full of "terbacker," and before he could unload and get his tongue into working order the woman had unloaded a whole grist of information. When we three bachelors saw such a company coming it was safe for us to bet that the woman was already wound up, and ready to go off like an alarm-clock.

In the northern borders of Mendocino Co. we struck a great hog country, and we all remembered the brilliant scheme of our friend Harry L. Jones, the gas-man. We made remarks that this would be just the country for him—swine on the hillsides and in the valleys. White-oak trees were plentiful here, and the hog fattened on the acorns. Cows that wander in the forests are often belled; but here the hog was belled as well. Such a one crossed our path, and the following inspiring scene occurred:

White o'er the mountain climbing,
We spied a pensive sow;

"BREAD! TWENTY-FIVE CENTS A LOAF?"

spirited man. The only watering-place for our horses in these little villages was in the shadow of the saloon; and while the horses were drinking, the driver was supposed to be in the saloon

Jack, our dog, espied her too,
 And then commenced the row.
 Upon her neck a bell was tied
 With heavy leathern thong;
 And how the bell did jingle, whingle,
 While she sped fast along.
 Dog and sow, with headlong leaps,
 Kicked up a blinding dust;
 She, intent upon her sty,
 She meant to reach or bust.
 It was no use for Wilder 'n' I
 To swing our arms and yell;
 In sad confusion, out of sight
 Went sow, dog, dust, yelps, grunts,
 And jangling bell.

In the northern portion of Mendocino Co. our surroundings began to change. We left the railroad away back in Ukiah, and the only route now to follow is the stage-road into Humboldt Co. About every 25 miles are located stations, and now and then a small town. The intervening space is an unbroken wilderness. The trees that had been familiar to us began to disappear, and the redwood, the northern fir, the madrone, and the beautiful California bay-tree, or laurel, were abundant. The latter is a rich honey-producer in its season of bloom.

Our roads, instead of following up one canyon and down another, now sought the highest ridge, and we followed its contour for several days. The highest point to which our road conducted us was at the Bell Springs ranch, about 4000 feet above sea-level. We had a splendid atmosphere which visibly affected our spirits for happy effects. Grand panoramas of mountain beyond mountain, away to the north; black volumes of smoke rising from forest-fires; now the scene shifts, and we plunge through a narrow wooded defile; now out upon a mere niche for a road upon the mountain-side. Here were evidences that the road had been taken out by a slide, and dumped into the gorge below. The road, now mended with logs, was liable to go out again during the rainy season. It was in this region that we could indulge, under the inspiration of Mr. Pryal, in those big camp-fires; two or three fair-sized logs, then smaller limbs, sent the flames and the sparks heavenward in a grand pyrotechnic display. Cornfields were not abundant; but when we did find one it had to pay tribute in roasting-ears; and here we were delighted to initiate our city friend into the beautiful rural practice of roasting and then eating the delicious green corn. With a rise in our spirits, etc., there was also a rise in the price of provisions. Bread, 25 cts. per loaf; hay, 25 cts. per sack. As we had to buy hay for long distances, it was necessary to load several sacks. Susan B. and the cart were loaded to their full capacity, and Mr. Pryal's attitude at such times was so striking that I greatly feared for his decorous bachelor appearance. Wilder took turns with him, however, in hugging the delusion. See sketch.

At Bell's Springs we were directed to a good

camping-place a few miles ahead, where there was plenty of water; but by some hook or crook the signs were not strong enough, and we missed it. We made a long drive in a vain endeavor to find water, and finally darkness compelled us to camp. Having a merciful feeling for our horses and dog, we broke camp almost before the gray of dawn appeared, and resolved to find water, even before we ate our breakfast. We were now in an abundant deer country; and as this was the hour for them to feed, our guns were loaded, and Wilder sat with rifle in hand, and expectant eye. His face would have a sort of lemonade-without-sugar appearance whenever Susan B.'s whinnies would reverberate through the forest; but in spite of the noise, when we made a sudden turn through a wooded gorge, hurrah! three deer—noble deer, with antlers long, and nimble feet, went bounding one after the other across the road and into the bushes. I brought the horses to a sudden stop, and crack! went the rifle. "Whoa, Reina! whoa, Keno!" The rifle went into the bushes with Wilder behind it. Soon another shot, and *we* had the deer. Pryal and Susan B. came up, and we all lugged the deer into the road and upon the cart, and again proceeded upon our journey. We could have shot every deer, but we wanted only one for our daily needs, and a shooting of more would be merely wanton sport. We soon found a residence and a spring, where lived our friend the blacksmith. We dressed our deer, watered our animals, cooked our breakfast, and, without further rest, prepared for the continuation of our journey.

HIVING SWARMS IN HIVES HAVING PART
 FRAMES WITH STARTERS AND PART FRAMES
 FILLED WITH COMBS OF BROOD,
 HONEY, AND POLLEN.

Question.—In hiving swarms on frames containing narrow starters, how would it work, by way of contracting the brood-chamber, so to speak, to put in two or three frames of honey, bee-bread, and sealed brood, placing such frames on the sides of the hive, instead of using division-boards? This would save the trouble of looking over the hives and taking out the division-boards later on, and give the bees a start at housekeeping.

Answer.—There are three things against such a mode of procedure, the first of which is, that the bees would be likely to fill those combs with honey as soon as the brood hatched out, thus giving the three combs solid with honey, instead of having that much honey in the sections, this thwarting the only purpose of contraction, which is to secure the first and best

quality of honey in the sections, and also to get the bees to work in the sections before they commence to store honey in the brood chamber to any extent.

Second, if the three combs had any great amount of sealed brood in them, so that the hatching of this brood materially strengthened the swarm, it would be very likely to result in swarming, or the issuing of "virgin swarms," as it is called, where a swarm of the present year casts a swarm. These virgin swarms always destroy the prospect of a good yield of section honey, for, as a rule, they are much more persistent in continued swarming to the end of the honey-flow than is an old colony. I have often had new swarms go to work with a will in a large number of sections, working till they were about two-thirds completed, and then, just as I was priding myself on having a large lot of beautiful honey from such a hive, had them swarm, and be so persistent in swarming that none of said sections would be completed, while the nice looks of the work they had begun would be spoiled through the long failure of its completion.

Third. But the greatest trouble with such a plan of working lies in the persistency of new swarms in building drone comb in the remaining part of the hive, where any part of it is supplied with any thing in the shape of frames filled with combs. Why this is so I never could fully understand; but an experience of more than 25 years along this line has proven to me that bees can not be depended upon to build worker comb during the first week after being hived, if there is any completed comb in the hive at the time of the hiving of a prime swarm. With second or third swarms, the case is different, as bees are more apt to build worker comb with a queen when she first commences to lay, and only unfertile queens accompany these latter swarms; and in this case the queen does not commence to lay till the bees are fully accustomed to their surroundings. But with an old or laying queen, she seems to adhere to the combs placed in the hive when the swarm is hived, going but very little on the new comb then building, the result of which is the building of store comb for honey, which is always of the drone size of cells. After the bees have built a frame or two of drone comb, and the queen recovers her normal egg-laying powers which she had before the swarm issued, then the bees will go on and build worker comb; but we have worker and drone comb all mixed through our frames, which is a condition an enterprising apiarist does not like, and one which, if allowed to remain, results in a diminished crop of honey each year. My advice to all is, use only starters in the frames in hiving swarms, or else fill all frames with foundation, or give all frames filled with combs. Frames filled with foundation mixed with those containing combs do much better than frames

having only starters when used with combs; but even this is objectionable, on account of the bees lengthening the cells of the combs given while they are working out the foundation, so that the combs are very thick when completed, while those on the foundation are correspondingly thin.

ITALIANIZING.

Question.—When is the best time to Italianize an apiary of 52 colonies without interfering with the honey flow, without buying queens for every hive? and when should the queen-cells be started for doing this?

Answer.—There is no time of the year in which queens are so generally superseded as immediately after the general honey-flow; and we can always rest assured that, when the bees are willing to do such work, then is our best time. With me, fully three-fourths of all the queens which are superseded by the bees are so superseded during the three weeks immediately following the basswood bloom, as that gives our main honey-flow. Knowing this fact I have for years done the most of my requeening at this time of the year, and with success which has always pleased me, without interfering with my crop of honey in the least. To this end I start a greater number of queen-cells than usual, from five to eight days before the expected close of the basswood-honey harvest; and when these cells mature, hunt out the old queen and dispose of her, giving a mature cell 24 hours after having removed the old queen. If cell-protectors are used, the cell can be given at the time of removing the old queen, thus saving once opening of the hive; for, as a rule, the bees allow a queen to hatch all right where a cell-protector is used. If the young queen hatches in an hour or so after giving the cell, or before the bees become aware that their mother is gone, they will sometimes kill her and start cells from their own brood; but if the cells do not hatch in less than from 12 to 24 hours after the old queen was removed, nearly every queen will be accepted all right. A plan which I often use at such times is to raise a lot of cells from my best queen; and, 24 to 48 hours before they will mature, give one to each colony having a queen more than one year old, using a cell-protector for each one, and placing this cell in the sections or anywhere I best can where the bees can cluster about it, without hunting out the old queen at all; when, if the bees have any notion to supersede their queen, they will accept of this young queen and destroy the old one. If they destroy the young queen I allow the old one to remain, thinking that the bees know what is right; and, 19 cases out of 20, where the bees decide on keeping the old queen I find she proves par excellence till after the honey-flow of the next year is over. This is something that does not cost much labor, and one which I have practiced often to my satisfaction.

IMPROVED HIVE-COVERS.

By B. Taylor.

Editor Gleanings:—I have read so many articles in the bee-papers lately about hive-covers that I have concluded to send you a model of the best hive-cover in the world. You know everybody nowadays marks their wares "The best on earth," hence I make my extravagant claim in order to be in fashion. I have used this style of cover for more than 30 years, and believe it to be the best, all things considered, of any in use, past or present. Before I had machinery I grooved them with a common panel-plow, with a narrow bit. The grooving is, of course, to prevent warping, which it does most effectively. You know boards warp because one side becomes longer than the other, caused commonly by one side becoming damper than the other; then the damp side expands, and pushes the board in a circle; the grooves prevent this pushing power, as they allow room for expansion without its pushing effect. I always put the heart side of the lumber up, and groove two-thirds of the way through in three or more

places, according to the quality of the lumber, a soft board being less inclined to warp than a hard one. I always paint the ends of the covers in the joint before the cleats are nailed on. I cut the tops in lengths before planing; groove them, then nail on the cleats; the covers are then placed on a carriage, and run under a set of planer-knives, and the most beautiful covers you ever saw are made at the rate of one a minute, each one entirely out of wind, and true to a hair's breadth.

Of course, you will ask the reason for the shallow grooves near the edges. It is to prevent the water from flowing under by capillary attraction. I paint both sides of my cover—the under side one and the top two coats of oil and lead. I now have covers made thus thirty years ago, as straight and true as when new.

I have tried all kinds of costly covers of more than a dozen styles, and would have none of them as compared with these simple plain boards. They are always convenient in the yard or in winter quarters; they pack in small compass when not in use; are the cheapest of all to make, and will outlast any complicated cover of several pieces; shed water perfectly, if properly made, and deserve their title, "B. Taylor's Handy hive-cover."

Forestville, Minn., April 15.

[This question of grooving a cover-board to prevent warping has been brought up before. We never tried it in our yards.—Ed.]

THE DIVISIBLE BROOD-CHAMBER.

THE QUESTION OF INFRINGEMENT, AGAIN.

[I had hoped that this question might have been drawn to a close in our May 1st issue. But Mr. Williamson felt that, as he had been an unwilling participant in the discussion, and that, as he did not know his opinion, given on page 268, was to be used for print, he should be given space for further reply. After some correspondence with Mr. Danzenbaker it was granted, on condition that he would allow Mr. Heddon to have the "last say." The article came, and I assume that the condition was accepted. In order to have the whole matter appear in one issue, and to end there, I sent a proof to Mr. Heddon. Mr. Williamson's article is as follows:]

Editor of Gleanings:—It was with mingled feelings of amusement and disgust that I read Mr. Heddon's "Reply to Attorney Williamson," and it is probably foolish to dignify such "reply" by any notice whatever. In fact, were not Mr. Danzenbaker's interests involved in the matter I should pay no attention to it, since the intelligent reader will perceive that the alleged reply is not an answer to my statements respecting his right to hold the Danzenbaker hive to be an infringement of his patent, but, rather, a mixture of irrelevant citations from Walker on Patents, misstatements of the law of patents, and reflections upon my veracity.

It will be a sufficient answer to Mr. H.'s reference to "paid attorneys" to call attention to the fact that, however interested an attorney might be to present his client's case to the best advantage, his interest and consequent bias could hardly be as great as that of a party whose interests are at stake. It is to be remembered that Mr. Heddon is most vitally concerned in the matter in controversy, and that it is *barely* possible that, under the tremendous influence of interest (I understand he gets \$5 for individual rights), he is quite as apt to feel under compulsion to "say something" as would a "paid attorney." I think that, under the circumstances, my statements are fully as worthy of belief as those of Mr. Heddon.

Mr. Heddon says: "Allow me to call the reader's attention to the fact that Mr. Williamson makes no mention of patent law in equity." Permit me to call attention to the fact that the only reference he makes to "patent law in equity" is in his statement quoted above. He may know what he means by "patent law in equity," and its bearing upon his case; but so far as his article is concerned he keeps his knowledge strictly to himself. I rather suspect, however, that he uses this mysterious phrase as a sort of verbal bug-a-boo.

I am surprised, and yet at the same time flattered, that one so well versed in patent law as Mr. Heddon claims to be should admit himself insufficient to cope with me by asking that opportunity be given his attorney to reply to me. It would seem that the gentle reader will be justified in inferring from this admission of Mr. Heddon, that there is some force in what was said in my heretofore published opinion. I am also somewhat startled at the exhibition of inconsistency in Mr. Heddon in his expression of

an intention to fortify himself with the opinion of a "paid attorney," in view of the preceding and succeeding paragraphs of his article. Surely he will not insult the intelligence of the reader by offering the opinion of a paid attorney in support of his case!

Mr. Heddon charges me with misleading statements and mistakes, and not only fails to support his charges in a single instance, but in an effort to make out a case of error on my part he is himself guilty of what he imputes to me. He says, "If Mr. W. knew aught of the state of our art he never would have mentioned 'top covers.'" I challenge Mr. H. to point out the place where I used this expression. On the contrary, I used the phrase "top or cover," and as Mr. Heddon's patent specification uses this exact phrase, he will probably not insist that such phrase is an inappropriate one, and conclusive evidence that the user thereof is unacquainted with the nomenclature of the art. If Mr. H. could not read these three small words aright, it is little wonder that he falls into grievous error in endeavoring to understand and apply the principles of that branch of legal science which has been characterized as the "metaphysics of the law."

In stating in his fifth paragraph that the claim rejected by the Patent Office and dropped by his attorney is covered by the last eight words of his claim 5, "substantially as and for the purposes set forth," he displays gross ignorance of patent law, and shows that he has not read the "great authority Walker" as faithfully as one should, who assumes to instruct and criticise others in patent matters. This fifth claim of Heddon's patent contains a good deal more than the eight words referred to, and whether or not he can ignore or omit parts thereof to suit his fancy will be made apparent by the following extract from the "great authority Walker," section 549:

"A combination is an entirety. If one of its elements is omitted, the thing claimed disappears. Every part of the combination claimed is conclusively presumed to be material to the combination, and no evidence to the contrary is admissible in any case of alleged infringement."

If Mr. H.'s mode of construing claims by leaving out limitations to suit the exigencies of the case is sound, then, logically, he can cut out every thing but the words "a bee substantially as and for the purpose set forth," and thus be in a position to charge the bees themselves with infringement of his rights!

I also invite Mr. Heddon's attention to section 186 of Walker, which reads as follows: "It is well known that the terms of the claim in letters-patent are carefully scrutinized in the Patent Office. Over this part of the specification the chief contest generally arises. It defines what the Office, after a full examination of previous inventions and the state of the art, determines the applicant entitled to. The courts, therefore, should be careful not to enlarge by construction the claim which the Patent Office has admitted, and which the patentee has acquiesced in, beyond the fair interpretation of its terms."

C. J. WILLIAMSON.

Washington, D. C., May 8.

[Mr. Heddon replies as follows:]

INFRINGEMENT.

Editor Gleanings:—As a rejoinder to attorney Williamson's adjoining article, it may not be out of place for me to say that I have not and never have had any ill feeling toward the gentleman, nor is it casting any reflection upon his character, as he would make believe, to state that he, being a paid attorney, dealing with law rather than fact, uses fancy to carry the case of his client. Mr. Williamson must not forget that most bee-keepers have attended circuit court, and know that the spirit of legal work is to leave no kind of stone unturned to advance the interest of the client. I feel that I must compliment attorney Williamson upon his ingenuity in endeavoring to make a case without any material.

Does it not seem strange that my quotations from Walker should be called "irrelevant," and "mis-statements," by the learned attorney? I quoted them word for word; and if they are irrelevant, would not your readers know it, without the gentleman telling them? and if not, of what use is his bald assertion, without any explanation, in Mr. Danzenbaker's case?

Mr. W. thinks my interest is great because I sell

individual rights for \$5.00 each. Perhaps so. I have sold over 500 such rights, and perhaps a hundred counties at \$25.00 each; and after nine years Mr. Danzenbaker seems to have discovered the value of the products of my labor, and at once employed an attorney to see if there was not a flaw in my title by which he might jump my claim.

As to patent law in equity, attorney Williamson did say there was no such law; but now, having discovered his mistake, he seems to admit that there is. He says I do not explain of what use equity is to me. I will endeavor to explain: Equity will undo and set aside every citation from patent law that Mr. Williamson has brought up in all he has written. It will examine the state of the art ten years ago, and give to me all that is mine. In other words, if Mr. Danzenbaker, aided by his able attorney, should be able to find a weakness in the title to my property, equity, as the word indicates, at once comes to my protection. For positive proof of the foregoing, I refer you to Walker's text-book, edition of 1885, page 401. This shows that my former statement, denied by Mr. W., is absolutely correct, and that alone clinches my entire argument, because that court of equity in patent law, established in 1870, will give me what is mine; and I call the learned attorney's attention to the fact that the brightest and best-posted bee-keepers all over the country—men who know vastly more of the past and present state of the art than any patent-lawyer would know—pronounced my invention startlingly new, unique, and original. Talk all you may of the technicalities of my title, and yet bee-keepers know that the Danzenbaker hive is nothing more nor less than an infringement of my invention, and that, if he wants to use his sheet-tin rest, he should use it independently of my divisible brood-chamber, and frames closely fitting each other and the case. I am daily in receipt of letters from bee-keepers with whom Mr. Danzenbaker is corresponding, and in nearly all cases they send me his letters to them. These letters lay special stress upon the advantages of the special functions of my hive, but not one line have I yet seen concerning a single feature claimed in the Danzenbaker patent. I respect the Danzenbaker patent, although I consider it upon worthless devices; but, whether worthless or not, I should keep my hands off.

Attorney Williamson knows so little about our art that he misunderstood me regarding "top-covers." I had no reference to the way he used the words, but the significant fact that he said *any thing* about covers *at all*. Bee-keepers will understand me. Regarding his quotations from Walker, they are fully answered and annulled by those I previously quoted in this journal, and found in my circular to bee-keepers. But, laying this all aside, the patent court of equity, the existence of which Mr. Williamson undertook to deny, will set these all aside, and give to me what is mine. This, Mr. Williamson, can no longer deny. Nearly every well-read bee-keeper knows better than does Mr. Williamson, what belongs to me. The learned attorney excels the bee-keeper only in the matter of legal titles.

I hardly think that my opponent should be proud, and "feel flattered," because I admit that he knows more about the legality of patent deeds, and their fitness to the property they intend to cover, than should a bee-keeper who has made patent law only a side-issue study. However, when I received proof of his subjoined article I discovered at once that I needed no patent-attorney to wipe out his arguments as a July sun would melt a snowball. But let me again compliment Mr. Williamson by stating that he has no case, as he evidently knows, and that bee-keepers of intelligence are all against him and his client; knowing, first, that the Danzenbaker hive has no merit except as it incorporates my special features, and that, after so doing, his changes and additions nearly ruin the hive. But you may rest assured, Mr. Editor, it will not be long before this court of equity will be tried, and I will endeavor to substantiate every claim I have made.

Please allow me to refer to the Train, Terry, and Harris patents, as cited by you in a former issue. In these patents, as in all others, it is a divisible *hive* and not a divisible *brood-chamber*, for specified purposes, that is referred to. We have always used divisible *hives*, but not divisible brood-chambers, as specified in my patent. Mr. Danzenbaker said truly that father Langstroth was robbed, but that I had nothing to be robbed of. That is just what they said when they were robbing Langstroth. How perfectly history repeats itself!

JAMES HEDDON.

Dowagiac, Mich.

MRS. HARRISON'S RETURN.

Last autumn my attention was directed to the lateness of the season in which bees were working—carrying water, and pollen gathered from asters in the river bottom, into November. I was requested to make a note of this as bearing upon the winter problem. The colonies were left upon their summer stands, protected in the upper story with chaff cushions. On my return from Florida, April 15, all of the colonies responded to my "How do you do?" with the exception of four. Since then, in cleaning out these hives, I judged from appearances that they were queenless in the fall. The past four seasons had been poor for honey, and, having other duties more important, the bees were left to their own sweet will. I shall hereafter consider the rearing of young bees in the fall as one of the adjuncts to successful wintering.

SPRING FLOWERS.

My way from Florida north was through perpetual bloom, extending to Southern Illinois, Alabama taking the prize. Her woods were in fitting garb for the Eastertide. Some of the trees that I was told by residents were dogwoods, were entirely covered with white blossoms, without leaves; others had green leaves among the white bloom. Pink honeysuckles, so light and fairy, were a thing of beauty, and, when once viewed, will never be forgotten. North of Montgomery the yellow jessamine was very abundant, climbing to the tops of the small pines, and bending their heads with the weight of bloom. Passengers came into the train carrying bouquets and baskets of flowers, and boys offered them for sale at the stations.

The orchards of Tennessee were in full bloom, and a passenger from Nashville informed the writer that they had had no fruit there for three years, but had great promise for this. I was surprised, on reaching Southern Illinois, to find the peach-trees in pink, and still more so on reaching home to find the buds showing pink in our garden. Fruit-bloom has been very abundant in this locality.

Peoria, Ill.

HOW TO PREVENT THE FLAT COVER FROM WARPING.

I see there is some trouble from cleated flat covers warping, and, in consequence, you have devised a new cover to take its place. Now, I have nearly 100 of the old covers, which have been in use from one to four years, and they never warp or check, and are as true as if made of sandstone. The bottom-boards are the same. This is the way they were put up: Before putting the cleats on the ends, the ends of the cover were given a heavy coat of white-lead

paint. The groove in the cleat was given the same, and put on and nailed into the end of the cover-board while the paint was still wet. They were then painted two coats all over, and the crevices filled with paint, so that the cleats were as secure as if they had grown there. The bottom-boards were painted on all sides; but the covers, being covered with tin, were painted only on the parts not covered by the tin, except at the ends. My hives are exposed to the sun and weather the year round. They are of pine, and were made by you.

ALBERT WITTENMYER.

Emison, Ind., Feb. 25.

[We never had any trouble with the flat covers ourselves; but a few reported that they did. The painting of the ends of all boards for cleated covers, of the old-style flat, or the new Higginsville, will add greatly to the durability of the covers.—Ed.]

HIGGINSVILLE COVER WARPING.

Editor Gleanings:—On page 13 of GLEANINGS for Jan. 1 you say, in footnote to my letter, "The Higginsville model, besides the cleats and gable strip, is made up of two boards; and theory as well as practice shows that the warping tendency of the one will correct that of the other." I am not much on theories, but I have had five of these covers in use four weeks; and although it is not yet summer they are warped and twisted worse than any flat cover I have. My covers must act differently from those belonging to others; for, instead of the "warping tendency" of one "correcting" that in the other, it seems to aggravate it. Two of the covers fit fairly well, except that the groove is too wide at the ends; and the thin edges of the covers curl up. Two stand on three legs, and the thin edges bow up. One does not fit down square, and the cleats are warped so as to almost let the thin edges out of the grooves. The gable strips of all are warped. I have not a single flat cover in the yard but that is in better condition. They are lighter, and blow off easier, though no cover is safe here unless fastened on or weighted.

UNCAPPED FRAMES OF HONEY GIVEN TO BEES IN THE SPRING.

I find from careful tests, that, from each pound of capped honey, the cappings if saved will make on an average about $\frac{1}{4}$ oz. of beeswax. This is quite an item when beeswax is 30 cents, and extracted honey 4 or 5 cents. I have saved as much as 50 lbs. of wax from 30 colonies, run for extracted honey (spring count); just from cappings with scrapings of hives and frames.

CLARK A. MONTAGUE.

Sang Run, Md., April 15.

[This doesn't tally with the experience of others along the line of covers. You say the cleats are warped so as to almost let thin edges out of the grooves. There is actually more wood in a cross section of the Higginsville cleat than of the ordinary flat cover. Under the same conditions it should warp actually less. You say further that the grooves are too wide

and that the thin edges turn up. This is not a fault of the principle but of the workmanship, and if you got the covers of us you are entitled to a rebate. You do not say one word about the use of paint. Without it I should not expect any cover to stand true. Well, let's have the truth, at all events. I'd like to hear from others.—Ed.]

WHY THE HEDDON HIVE IS NOT APPRECIATED.

The reason some apiarists fail to appreciate the many advantages offered by the Heddon hive is that they do not understand the peculiar system of management which the successful manipulation of this hive requires. Mr. Heddon seems to think he is not called upon to promulgate this system till he gets ready; but I say he has no right to patent an article and then withhold from the interested part of the public any thing essential to its use; for by such patent he debars others from discovering the patented principle who would place it before the public in a shape that it could be used.

In the Heddon case, the hive is secondary to the system of manipulation which it admits of; for without such system the hive is no better than, if as good as, the Dovetail; but having a knowledge of the proper way to handle the hive, one can do from two to four times the amount of work in a given time that he can with any other hive.

Loss in this (Linn) county, 95 per cent for this winter. F. H. RICHARDSON.

Laclede, Mo.

MUD-FLINGING OR HOLLOW PRAISE.

Dr. Miller, in a recent *Stray Straw*, refers to a "good time" Editor Leahy had with J. T. Calvert, and proceeds to remark: "Now, you can fling all the mud you like at the mutual-admiration business; but that sort of talk makes a good bit nicer reading than mud-flinging." Has there been any "mud-flinging" in regard to this matter? Is it fair to use a term of this kind to characterize disapproval of a too liberal use of "taffy" in certain quarters? Honest criticism should include commendation when it is deserved, as well as the pointing out of faults; but there is such a thing as flattery, and it is most abominable and mischievous. Are there not often words of praise in the bee-journals that every one knows to be mere hollow compliments, intended to make and keep those to whom they refer good-humored, pleased with themselves and with others? Is it not plain that there is a virtual compact in some quarters, "you scratch me and I'll scratch you"? Is this manly, truthful, not to say Christian? One of the wise and good men of the olden time said, "Let me not, I pray you, accept any man's person; neither let me give flattering titles unto man; for I know not to give flattering titles; in so doing my Maker would soon take me away." We are taught on high authority that "a man who flattereth his neighbor spreadeth a net for his feet," wherein

he is likely to be tangled with vanity and pride. Again, "He that speaketh flattery to his friends, even the eyes of his children shall fall;" i. e., they shall lose the power of moral perception, and be unable to discriminate between truth and falsehood, good and evil. One of the grandest characters that ever lived in this world could appeal to those who knew him and say, "Neither at any time used we flattering words, *as ye know*." I wish every writer in the bee-journals could truthfully say this, and that there might be an end to all vain and fulsome flatteries. Flattery is lying, and a liar is despicable. The dictionary definition of "flattery" is, "To inflate with blandishments or exaggerated praises; to deceive with fair words; to cajole; to wheedle; to coax; to attempt to win by artful compliments; to soothe or gratify by praise or obsequiousness; to please a person by applause or favorable notice; to compliment." It is time the columns of the bee-journals were for ever closed to this kind of thing. WM. F. CLARKE.

Guelph, Ont.

[What Mr. Clarke has to say is very good—yes, excellent; but that bee-journals or bee-keepers are frequent offenders in the use of "words of praise . . . that every one knows to be hollow compliments," GLEANINGS is not prepared to admit. There has been no "mud-flinging" at the "mutual-admiration society" so called; but there is such a thing as mud-flinging at individuals that is ten times more "abominable and mischievous" than any flattery I ever heard or read.—Ed.]

PETITION.

Whereas, the Hon. Secretary of Agriculture, in his last report to the President, says, "The Entomologist strongly recommended as a part of the work of this fiscal year the attempt to introduce into the U. S. from Ceylon the 'Giant bee of India,' *Apis dorsata*," and

Whereas, it now remains with the bee-keepers and farmers to unite in petitioning the proper authorities to carry out the work recommended by the Entomologist, therefore,

Resolved, That we, the bee-keepers of Ontario Co., N. Y., in convention assembled, respectfully ask the publishers of the bee-papers to print and distribute with their paper a petition to be circulated by each subscriber, the extra expense to be shared pro rata by the various bee-keepers' societies throughout the United States.

CLOSE-FITTING FRAMES.

Close-fitting frames, as Mr. Heddon uses, won't do south. They will swell so at times, especially in winter and spring, that they can't be pried out. I knew from trial, and I had more play than he gives. A. F. AMES.

Claremont, Va.

DIXIE LAND; THE VERDICT OF A MAN WHO IS NOW IN CALIFORNIA.

I read A. I. Root's southern travels with the greatest interest. What he says is every word correct. When he says that Dixie is "just slick," he is right. I have been over Uncle Sam's domain, and know of what I speak. Taking it all in all, the South is hard to beat. If you look it up you will see where you shipped goods to me in the State of Washington. I lived five years in Florida, fourteen in Texas; was raised in Kentucky. I lived in Washington ten years, and this is my second year in California. I spent five months in San Diego Co., and have a tolerably fair idea of most places, and my choice is Southern Alabama.

Upper Lake, Cal.

G. P. SHIRES.

[If our readers will turn to page 355 they will see that Rambler mentions meeting friend Shires in California.—ED.]

BEE-STING POISON, ETC.

Bees are doing finely. I had 26, spring count, now 56. Last evening I transferred the Italian colony from the box hive to one you sent. Twice in my lifetime bees have thrown something into one of my eyes. It smarts and turns red immediately. I have never heard of any one else who is troubled in that way.

Box Elder, Va., May 18.

J. H. ALLEN.

[Friend A., I have many times, while near angry bees, felt the sensation you describe; but, as you mention, I do not know that I have ever before seen it in print. Sometimes when you open a hive during cool weather, cross hybrids will elevate their stings, and you may see a little drop of poison hanging to the sting. If you take the trouble to taste this you will find it a very pungent, acrid poison. Now, I have sometimes thought that an angry bee might, while on the wing, flit or throw this poison so it might go into a person's eye. Under similar circumstances we often smell what we call bee-poison. In preparing stings for medicine this is quite perceptible, and some people seem to be disagreeably affected by being around when this poison seems to be very much in the atmosphere. Very likely it is more or less volatile, and the odor of it in the air may affect the eyes, and perhaps other organs. Can somebody tell us more about it?—A. I. R.]

DESTROYING SWARMING-CELLS: LANGSTROTH VS. SECTIONAL BROOD-CHAMBER FOR THE PURPOSE.

In that valuable article by E. France, in GLEANINGS, Dec. 15, on out-apiary management, he puts the key to his plan of swarming-time management by periodic visits in a line or two of print, and it is a pity, seeing the amount of work and care involved in following his instructions, page 934, viz., "*Be sure no queen-cells are left in any colony,*" and, further down, "*Leave no queen-cell in the old colonies,*" to let it pass without comment. It is truly good sound advice; but with the L. frame and hive, how laborious! how risky! all hinges on *not one cell being missed* in the work of destruction. A mere cup with an egg in it, accident-

ally overlooked, means a swarm issuing before the 10th day comes round, and with it the apiarist. This plan of getting the swarming-date of a number of colonies on the same day, so dispensing with a watcher, is one I have carefully studied and followed in my out-apiaries for three seasons past. But I give them now but nine days between visits; and when there, instead of destroying cells one by one, I turn each of the brood-cases upside down, which effectually and positively destroys all embryo queens, and none can escape, and the colony is safe for nine days. This colony is swarmed on next visit; also all others like it previously inverted. The other colonies are inverted if strong, or likely to swarm; and if they have cells sealed next visit, they are swarmed in their turn; but if they have young cells, or none at all, they are inverted again and are safe till next visit, and so on with all hives as they advance to swarming strength every nine days for the two or three months of our swarming season.

This inverting has other advantages that have been set forth by other writers, including Mr. Heddon, whose hive, or a modification of it with hanging frames, I use in my out-apiaries; but I have not seen its superiority in this respect, and the rapidity and certainty which with it the cell destruction essential to such a system of periodic visits can be accomplished, set forth anywhere. Any easily inverted hive would have the same advantage over non-invertible as the Heddon type has. Inversion is not a mere fanciful and pretty idea; it is to me the key of out-apiary success, and does away with all need of swarm-catchers, and hivers and traps and appliances outside the hive itself.

T. BOLTON.

Dunkeld, Victoria, Aus.

I have had the same trouble John K. Goodrich had. Some thieves carried away three hives of bees at different times, and the arrangement spoken of in GLEANINGS seems to be just the thing. Would you please tell where such a battery could be bought? Others might be glad to know.

GUSTAVE GROSS.

Milford, Wis.

[A battery and an electric call-bell outfit can be purchased at any of the electrical-supply houses for about \$2.50. Write to Stanley & Patterson, New York City.—ED.]

THE STRENGTH OF BEES.

A French naturalist, Mr. Plateau, has tested various insects to ascertain their strength, and finds that the smallest ones are very often the strongest. According to his experiments, a bee can drag off 30 times as much as a horse can, according to its size. One bee dragged easily 20 others, and showed a power proportionate to a locomotive. What astounding muscular power the bees must have, we think, when we

remember that the weight of a whole swarm hangs from a limb, when but comparatively few bees touch the limb itself.

Medina, O., May 23.

K. R. MATHEY.

SOME UNSCIENTIFIC AND INACCURATE TEACHING CONCERNING BEES, IN A COLLEGE TEXT-BOOK.

Mr. Root:—In a book at present used in the State Normal College, in Albany, entitled "Comparative Zoology, Structural and Systematic, for use in Schools and Colleges, by James Orton, A. M., Ph. D." new edition, revised by Charles Wright Dodge, 1894, Harper Bros. publishers, I find the following statement in relation to the bee:

"They exhibit three castes—females, or queens; males, or drones, and neuters, or sexless workers. There is but one queen in a hive, and she is treated with the greatest distinction, even when dead. She dwells in a large pear-shaped cell, opening downward. She lays three kinds of eggs; from the first come forth workers; the second produce males, and the last females."

I send this as a bit of curiosity, showing how the colleges are advancing(?) in bee-knowledge.

Menards, N. Y.

JACOB KAUTZ.

[Such scientific (?) teaching is disgusting. If it is a fair sample of the accuracy of the other matter in the book I should be sorry to have my boy use it as a text-book. The authors evidently got their knowledge on bees, such as they do have, from a very careless reading. It is very unsafe for *any one* to write on the subject without a little practical experience to throw light on what he is reading. Prof. Comstock's book, notice of which appeared on page 409, last issue, is in marked contrast. Prof. C. went to the bees himself.—Ed.]

Eight extra pages as usual.

The *Apiculturist* for March, April, and May is here, bound in one cover, but not any farther for the consolidation. Is it a quarterly?

"REV." is the title in front of Emerson T. Abbott's name, as printed in the *A. B. J.* That may be a Rev-elation to some; but it belongs there, and deservedly.

THE new bee-paper, the *Southland Queen*, is out, issued by the Jennie Atchley Co. It contains 22 pages and a cover, and is edited by the Atchley family. Monthly, \$1.00 per year.

THE accurate and scholarly typography of the *British Bee Journal* is a pleasure to those who are pleased in that way. In this respect it presents a marked contrast to—some of us.

THE late frosts that have prevailed throughout the country have done a good deal of damage; but we hope they have not affected the nectar-bearing flora that will come on later.

AFTER a trial of 30 years, Dr. J. P. H. Brown, in the Southern Department of the *A. B. J.*, says, "I am satisfied it does not pay to cultivate plants exclusively for the amount of the nectar-secretion."

E. B. WEED, in the *Canadian Bee Journal*, claims that the bleaching of wax in sunlight gives a better result than by the use of acids. We believe that is the position taken by Mr. Mathey, whose articles on wax we are now printing.

WM. McEVOR, the foul-brood inspector of Ontario, reports bringing 109 colonies through the winter in good condition, not losing one. That's something on the Boardman style; and several others in Canada report wintering with little or no loss.

FOR the first time since *Stray Straws* were published, we have failed to receive our installment for the current issue. We have not learned the cause up to the time of going to press. Kind o' suspect the doctor prepared them, put them into an envelope, then into his pocket, and forgot to mail 'em.

DURING the preparation of a part of this number I have been somewhat under the weather, but I am now coming around all right. The consequence is, most of the editorials were written by W. P. He prefers to use the editorial *we*, because, he says, it rhymes with P. So you can designate his by the use of "we."

WHAT shall the harvest be? is a conundrum with bee-keepers all over the land. Indeed, it is a conundrum every year; but it seems to be more so this year than ever. Mr. Harry Lathrop, of Wisconsin, writes that the prospect is poor. Last year Wisconsin suffered terribly from the drouth, and many of the bee-keepers obtained little or no honey; but Mr. Lathrop did well.

WE copy the following from the *Newaygo Republican* of May 9. It fully accounts for the fact that Bro. Hilton has been missing for some time.

Hon. Geo. E. Hilton returned from a week's stay at his home yesterday. He is receiving many congratulations from his colleagues upon the fact that he is the proud father of a nice little girl. Time bears out the prediction made in the first of this series of letters that Mr. Hilton would prove to be one of the most popular as well as active and useful members of the House. No man is more highly respected than he, and no man in either House has more friends. He has much influence; and it is

needless to say to Newaygo County readers that it is never exerted in a bad cause.

IN the *Apicultural Review* (Spanish), published by Mr. Andreu, at Mahon, Balearic Islands, near Spain, we learn that indications for a good crop of honey are very favorable—plenty of rain, and an abundance of flowers. The editor says the price of wax is steadily going up, while that of honey is continually going down. He recommends the policy of keeping bees for wax only; and his article on the "Production of Virgin Wax" is so timely that we will translate it for a future number.

WOOD-BASE FOUNDATION, AGAIN.

SINCE our mention, in the last number, on p. 408, of Schmidt & Thiele's foundation, we have received another sample having a very much thinner wood base. S. & T. write concerning it:

We herewith send you another sample of our veneer foundation. The veneer we use now is only $\frac{1}{8}$ of an inch thick. This will not warp, or trouble in cutting queen-cells, and is still strong enough to keep the combs from melting, sagging, breaking, falling out of frames when handling or extracting.

This is a big improvement over the first sample received. Of course, it can not possibly sag, and would, I have no doubt, make good brood-combs; but I am still inclined to think it is more expensive than ordinary brood foundation such as is generally sold. A great many times old things that have been discarded and declared valueless in the past, have come up again and demonstrated that there is something of value in them after all. Possibly the wood-base foundation of Schmidt & Thiele may be one of the things of this kind. I have no doubt they would be glad to send samples to any one desiring to see it. Their address is New London, Wis.

THE STANDARD DICTIONARY—A GREAT WORK.

AFTER five years of labor on the part of 247 editors and a host of helpers, and the expenditure of a million of dollars, this superb dictionary is finished, and it is far ahead of what the publishers promised at the outset. It defines every English word and its derivatives, with every shade of meaning, in every branch of science and art, making a total of 301,865 words, or 55,000 more than Webster's International. The time has past when any one man might write a dictionary of our language; hence on the Standard a specialist was engaged on every line of human thought and work, such as astronomy, botany, chemistry, electricity, physiology, etc. In defining apicultural terms, for instance, Dr. C. C. Miller was engaged. When Webster's latest edition was published we were surprised at some of the apicultural definitions, especially under the word "Propolis," which is spoken of as forming the capping of honey-cells. Finding it was too late to have any corrections made in Webster's, we immediately wrote to

the publishers of the Standard, which was then completed only to the letter B, and urged them to secure the services of Dr. Miller on behalf of bee-keepers. They did so just in time, for the old errors were beginning to show again as the word "Bee" was reached. The publishers immediately corrected the type so as to correspond with the suggestions. So far as apicultural terms are concerned, we find no room for improvement nor ground for complaint in the Standard. This is not intended as an invidious comparison against the International, which, at the time of its publication, was the best dictionary ever printed, but to show the great advantage the last one has in profiting by the mistakes of others. The publishers of the Standard have had some of the most prominent editors of Webster's, The Century, Britannica, and other lexical works, on their own staff, and have left no means untried for securing information wherever it could be found. The English press as well as American pronounces the highest eulogies on the Standard.

The defining part of the book contains just 2100 pages, printed in very fine type, copiously illustrated with new cuts (about 5000). Birds, badges, colors, coins, flowers, precious stones, etc., are shown in their natural colors, and not all in dull black. The different parts of modern machinery, such as engines, type-writers, knitting-machines, looms, etc., are fully shown and numbered; also the bones, veins, muscles, etc., of man and animals. The locomotion of dogs and horses is shown by numerous pictures taken from snap-shot photographs that were taken at different stages of the step, run, amble, or leap. This feature is very unique. The book not only describes the word "apple," but describes fully every known kind—about 368; and when it comes to the weights and measures of the world, one feels lost as in a labyrinth. The principal words used in all the arts, such as architecture, carpentry, printing, etc., are grouped by themselves, besides being defined in their proper place. Some 218 pages are devoted to grammatical corrections, pronunciation, foreign phrases in several languages, disputed spellings, etc. The quotations used are on the side of morality, Christianity, and temperance.

The printing of the book is as good as human skill can make it—every page being like those found in our standard magazines, and the binding corresponds. But the best idea the reader can obtain of the book, without buying it, is to send 10 cts. for sample leaves of it, which will show more at a glance than we can say for it in a day. Address The Funk & Wagnalls Co., 30 Lafayette Place, New York.

This is not a paid "puff" or editorial in any sense of the word. It is written without any knowledge on the part of the publishers of the Standard, and simply because bee-keepers will find the book to be so reliable in defining apicultural terms.

HONEY FOR HORSES.

You may suggest it would be a rather expensive feed. Well, circumstances alter cases. It may not be so expensive after all. Listen. Friend McMillan wanted a pony to go to town with, and to run around the neighborhood. A neighbor offered him a mustang at a very low price, because the animal was vicious and unmanageable. Friend M. and his good wife, however, decided they could educate the pony to be useful, and the neighbor brought him over. It took two men to deliver the new purchase—one to drive and the other to lead the horse by the bits; and as it was, they came in sweating and puffing, and seemed very glad indeed of the privilege of turning over the property to its new owner. How did they make out? Well, it was my pleasure to have very many pleasant rides around the country with that same pony. Now for the secret. I have heard of \$50 secrets, and I do not know but this one would add \$50 to the value of very many a balky or vicious horse. I think the credit of the discovery belongs to the good kind-hearted Mrs. McMillan. I suppose you have heard it said that the shortest cut to a man's heart is down his throat. Everybody knows it is not true, but there may be a *grain of truth* in it. Well, Mrs. M. set out that very first day to win not only the affections but the good will of the mustang pony. She gave him bread and butter and honey to start with. Come to think of it, I do not know but the butter was left out, and so it was only bread and honey. The tempting morsel hit the spot exactly; and after the pony had had a good slice of bread, with a liberal allowance of honey, he would nod his head with satisfaction, and do almost any thing they wanted him to, for a *whole hour*.

We were late in starting out; but when we got hitched up, and I was in the buggy, the pony made a bee-line for the back door of the kitchen. His benefactress came out to give him an approving word; but friend McMillan said we were so late we shouldn't have time to wait for him to have his accustomed sweets. The pony looked terribly disappointed, and evidently had almost a mind to go back to his old life, and act badly. I plead for him; but friend M. said he was old enough to behave himself without being coaxed like a baby *every* morning, and made him go on. He went very well till we came to the store and postoffice; and I presume, as this was a frequent program, he expected us to turn back and go home, refreshing himself by the way, no doubt, in thinking how nice that bread and *honey* would taste when he got back. His master, however, had planned a long trip for him, before getting home; and when his head was turned in another direction we came so near having a circus performance right in the public street that I wanted to get out. My companion, however, assured me he would bring his horse around all right in a few minutes. When I questioned him as to how he *knew* he would, he said they two had had a good many rough-and-tumbles in the sand, and the pony knew that *he* knew who came out on top every time at the ending. So the pony, philosophizing, evidently, that "what could not be cured must be endured," took us all over the surrounding country before we got home. I want to stop right here long enough to tell Mrs. M. to go and give that pony an extra piece of bread, well sopped in good

honey, just the minute her eyes meet this in GLEANINGS.*

In the neighborhood of Fort Reed is a most beautiful country residence belonging to Rev. Lyman Phelps, whose writings perhaps many of you have seen in the religious papers. He has not only a magnificent orange-orchard, but peaches, pears, strawberries, and ever so many other fruits right along the margin of one of the prettiest little sheets of water (Silver Lake) to be found in Florida.

Sanford has something unique in the way of sanitary arrangements. The sewage is in a series of open ditches, covered only at street-crossings. Well, at the head of each street, away off at the back side of the town furthest from the lake, an artesian well has been put down. I think they have to go something less than 100 feet in order to meet an immense flow of water. These artesian wells send a sufficient current over and into the lake to wash all the filth and every thing else out of the open ditches as soon as it falls in. One feels like protesting against such a waste of water; but everybody says the supply is inexhaustible. No matter how many wells you put down, or how large, they just flow and keep flowing, year in and year out; and yet with all this abundance of water, that runs of itself up to almost any height desired, it is only here and there that it is as yet made any use of for irrigation.

I had arranged to meet Constance, who was stopping with relatives in Jacksonville, at Sanford; but there had been no very definite appointment; and hunting for strangers away down in the interior of Florida, when you didn't even know when they would be along, seemed a good deal like hunting for needles in a haystack. I inquired for Mr. Ming, a cousin of mine, connected with the Orange-belt Railroad; but although all the railroad men assured me he was a "mighty good fellow" nobody could just then put his finger on the man. I began to get somewhat homesick. I always do when I have time, therefore I usually manage when away from home to avoid having time for any such recreation. I was up very early in the morning, before any one else was stirring. I finally met a porter who was hustling up a drummer that he might not miss his train. I felt restless, and wanted to go somewhere, so I concluded to go on the same train with the drummer. It was on the Orange-belt; and just as soon as I stepped aboard I almost ran against my cousin, Mr. Ming. He said the women-folks, Constance included, would be in on the afternoon train from Jacksonville. It did not stop raining just that minute; but if you had looked into my face you might have thought there was very bright sunshine everywhere. Now, perhaps some of our readers do not enjoy having me tell about how an unseen presence often seems to guide my steps. When I arose that morning I prayed earnestly, and yet I am afraid with very little faith, that God would direct me on that rainy morning, so that I might find Constance and my relatives. As soon as I heard the porter say this man would be late for the train, without knowing *what* train, or on

*Every bee-keeper knows how passionately fond of honey bears are. Well, several circumstances seem to suggest to me that this strong love for this peculiar form of sweets is not confined to Bruin alone. Bruin, by the life he leads, has an opportunity for discovering honey, and to satisfy his craving for it, while other animals have not; and may we not take advantage of this strong liking and use it to put a horse on his good behavior? Will somebody test it on a balky horse, and report? After he has acquired the appetite, the honey would surely serve to divert his attention from his "sulks," if nothing more.

what road, I felt a strange longing to take that very train too. I had just been feeling that I must do something, or go *somewhere*, that dreary, rainy morning, and the way seemed to open almost of itself. Do you remember that old hymn,

He leadeth me ?

Mr. Ming said he was going down to Oakland, and would be back in the afternoon; and as I had nothing else to do he said I should come along and look at his road, and see the country. As we passed through Palm Springs I got just enough of a glimpse to feel sure I wanted to stop there. A little further on we passed, quite near Oakland, a solid hundred acres of oranges. Over the arched entrance to the grounds I read, "Forest City Orange-orchard." I was told by my companion that it belonged to some prominent merchants in Cleveland, O.

Constance was evidently as much delighted in the afternoon to find her father where she least expected him as I was to see her. Before leaving Oakland, however, I got a chance to run up to Palm Springs, and investigate. In a little shady nook were great palm-trees that threw their protecting branches all over and around, and a beautiful crystal spring boils up, sending out a volume sufficient to make a good-sized creek. The waters are just warm enough for nice bathing, and there are seats arranged on the mossy banks, making it a most inviting place for picnickers or pleasure-seekers. Learning of a bee-man only a mile and a half away, I walked out to see him, and met a generous welcome. He had suffered by the frost, but was very busy putting his ground in good shape again to put in another crop. The bee-hives, the fruit-trees, the different buildings for poultry, grain, domestic animals, etc., scattered through a large dooryard, made one think of the old-fashioned farmhouses. While others were complaining, and saying that farming does not pay, and that there was no use of planting any more orange-trees, nor in *fussing* with them any more, he and his good wife were bright, hopeful, and enthusiastic. "Why," said he, "Mr. Root, I sold over \$600 worth of oranges right out of this dooryard, in 1894. Why should I give up and get discouraged?"

The Orange-belt Railroad has packing warehouses along its whole length. Sometimes it seems as if there were an orange-house and station every mile; and, in fact, some of them are less than a mile apart. In consequence of the freeze, however, business was, as might be expected, dead, and things looked dull.

Our party left Oakland in the afternoon, catching me on the train, and went through to Tarpon Springs that Saturday night. On the way to Tarpon Springs we passed through the great tomato regions round about Claremont and the strawberry-farms near by. We passed the Sabbath at Tarpon Springs. Here, as in almost every town in Florida, were very pretty churches, filled with good audiences who listened to able and intelligent pastors. Tarpon Springs gets its name from another of these wonderful springs, connected, evidently, with the artesian water. This spring is so great that pleasure-boats of all kinds run out into the lake and gulf adjoining. This water, however, has a dark color, similar to that I have spoken of that gets its hue from the roots of the saw-palmetto. Iron pipes have been screwed together, and pushed down into the crater of this spring some 200 or 300 feet. They did not touch bottom even then; but the sides of the cavern presented so many shelves that the rod would strike on a projecting shelf and prevent going down any further. Well, this spring is intermittent, and it is supposed to have a subterranean connection with a lake several miles

away. The water in the lake is dark, like the waters of this spring; and during a severe drouth, when the lake is nearly dry the water stops running. Is it possible that the artesian wells of Florida are fed by the multitude of lakes standing on higher ground? Almost the entire soil of Florida is so sandy the water would readily get down through into the rocky strata composed of coral, and the phosphatic rocks that are opening up such a great industry just now.

We stopped at a hotel called the Ferns, and I for one came pretty near falling in love with the Ferns, the town, the spring, the people, and especially with the old white-haired pastor of the Congregational church. I called on him before services, and then had the pleasure of listening to his talk to the Bible-class before preaching.

At an early hour Monday morning we stepped off the train at St. Petersburg, at the southern termination of the Orange-belt Railroad. The first thing that enlisted my attention was seeing horses and wagons, away out in Tampa Gulf, not only half a mile, but a whole mile from shore. These wagons went out to get freight from the boats, and there was a regular traffic back and forth all day long, taking advantage of the rise and fall of the tide, as a matter of course. The bottom of the bay is hard firm sand, and level enough to be good wheeling. They say the horses have learned the trade so well that they go out in the water anywhere, providing they can keep their noses above the surface. But I tell you it looks funny to see a regular traffic going on all day long, sometimes with the horse, and wagon too, almost submerged with the exception of the box holding the merchandise. I suppose they have regular pathways, and know where they can go and where they can not. When the tide is out, people walk along the sandbars out into Tampa Bay for fully half a mile. The sand is clean, and furnishes nice firm walking. The Orange-belt Railway has a new pier which runs out from shore a *full mile*. They evidently expect to be ready for business when it comes again.

St. Petersburg is a great fishing-point. There are crowds of tourists fishing all day long, almost the whole length of the pier; and I am told there are parties who furnish tackle and bait; and not only that, they put the bait on and take off the fish. All the stranger has to do is to take the pole, throw out the line, and pull them in. All this is provided *free of charge*. You can fish to your heart's content without soiling your fingers, or investing a nickel in any thing. Why, this ought to be the fisherman's paradise. Even fine ladies can fish, and wear their kid gloves. Oh! by the way, perhaps it were well to mention that all the fish caught belong to the *owner* of the fish-poles, etc.

Our party took dinner at the big hotel—price 75 cts.; and the house was so full of guests that one sometimes had to wait *two hours* to get a place at the table. Now, you do not know A. I. Root very well if you think he is going to wait two hours for dinner. Just ask Mrs. Root how *she* thinks such a program would work. Well, I found a little humble restaurant called the Woman's Exchange. There was not very much style about it, but I found every thing neat and clean, and they gave me a great abundance of nicely cooked fish (such as they were catching all the while out on the pier), and the bill was only about 25 or 35 cts. This included coffee, potatoes, bread, and sauce. The Exchange is a branch of the W. C. T. U. work. They were nice friendly women, and they told me their principal reason for starting a res-

taurant was, there was no place where one could get a comfortable meal at a moderate price without going to the whisky and beer saloons. Of course, I do not give thanks out loud when I sit down in a public restaurant, but I several times gave loud thanks all to myself for the privilege of finding a place where I could get my dinner, supper, or breakfast, right away—well, say as quick as Mrs. Root would get it herself—and be waited on by good, pure, clean Christian women. When I contrast such a place with those I am sometimes obliged to put up with—say a meal of victuals served in a beer saloon—I should call the temperance restaurant a little heaven here on earth compared with the other place. You can call the other place what you choose. Now, when you go to St. Petersburg, just go into that Exchange and say an encouraging word to them. Constance thinks I am a little extravagant in my praise; but I am just giving you *A. I. Root's* opinion.

About six miles out from St. Petersburg I found our friend Charles Norman, whose articles have made him more or less acquainted with our readers. He is located away out in the wilderness, on the shores of the Gulf. His occupation is, bringing in garden-stuff, fish, and oysters to the town of St. Petersburg, especially to the large hotels. He too had suffered by the frost, and was, I fear, somewhat discouraged. The oyster-industry, however, was comparatively unharmed, and he and his boys take oysters to town two or three times a week. Right near his residence is a shell mound of pretty fair dimensions that was not made by the mound-builders of ancient time. The oysters are brought in by boat, and removed from the shells near the home I have mentioned. Now, that these shells may not be scattered all over his grounds, and occupy valuable land, the "shucking" is done on top of the heap. As the shells collect, the tools, etc., are pulled higher up; and finally they sit at their work on a heap of shells that bids fair, in a little time, to reach as high as the dwelling; and I was surprised to see how great an accumulation was made in just a few years as the result of the oyster-trade of just one person. Friend Norman has a very neatly arranged apiary under a great scuppernong grapevine, if I remember correctly. Most of the hives in Florida are shaded in this way during the great heat of summer.

About half way between friend Norman's and St. Petersburg I had my first glimpse of a good-sized wild alligator. I should have called it a log of wood on a pond of water; but the colored driver told me that this "gator" had been there for years. He has got a deep hole dug in the center of the pond; and when they try to capture him he buries himself down in the mud. He was lying partly out of the water, blinking his eyes in the sun as we passed by. It was near this spot, on our way home, that I met Thaddeus Smith—see page 219. Mar. 15. I need not tell you that friend Smith and myself had a "big visit;" and I, at least, am looking forward in anticipation of another visit some day up here in Ohio, where we both live. Friend S., like myself, was accompanied by a grown-up daughter. It seems a little funny that we bee-keepers must wait until we meet each other a thousand miles or more from home before we can become really acquainted.

Toward night I shook hands with Constance and the cousins, and they started back while I took passage on the steamer for Manatee. For quite a little while I felt homesick again, and consoled myself with studying the winds and the waves. Before reaching Manatee we passed through sea-water which looked almost like whitewash—I suppose owing to the exceedingly

white sand that was so fine the wind and the waves had mixed it mechanically with the water. At the pier I found my friend J. W. Bannehr, who lives about a mile and a half out in the country. The orange-trees here near the water, the most of them, held their leaves; and although the fruit was somewhat injured it was shipped almost every day to some extent. On account of so much sand I left my wheel at Sanford; but I greatly enjoyed my walk out in the country. For almost the first time I found green fields—yes, an acre or two of oats. You will remember grain is raised to a very small extent, and only in certain localities, in Florida. Finally I came on to a very pretty home with a neat fence around it, bee-hives stationed out among the orange-trees, and every thing so neat and tidy it reminded me of the English friends of my boyhood that I have spoken about in our book, "What to Do." Yes, friend Bannehr's people are English. They came from London. They first came to Florida some years ago, stayed two or three years, and got homesick, and finally returned to "Merrie England." But after they had stayed *there* a year or two they became more homesick than ever to go back to Florida. They came back here and located, evidently to stay the rest of their lives. Friend B. has good substantial fences all around his premises; then he has good substantial gates with corresponding fastenings. Why, it brought to mind vividly the gates and fastenings that Mrs. Root's father used to have down on the farm by the river. I was so much pleased with the gate-hinge that I am going to describe it right here. It is simply an iron rod driven in at each end of the stick forming one side of the gate. The bottom rod rests in a hole made in a stone set in the ground. The top pivot simply goes through an auger-hole in a piece of board nailed on the cap of the fence. Here you have a hinge that permits a gate to swing either way. It will never wear out; and if the gate ever sags, just pry out the stone a little that holds the bottom pivot. Right here I have in my notebook,—

"Five colonies increased to 28, and a big lot of honey."

I do not know whether friend B. did this or not; but I suspect he did. His hives are all set up on a little pedestal or stake. They are up about two feet from the ground; and in answer to my question he said it was to get them out of the way of the toads, and then he told me the following

TOAD-STORY.

When he first commenced keeping bees he noticed one colony so much depleted that he thought there must be some cause for it. Watching closely he discovered, just at night-fall, a big toad scratching on the entrance-board. You know the rest. Being of a humane disposition he picked Mr. Toad up and carried him away off down to the river, and carefully dropped him in. But there were more toads, and he kept carrying them away. Finally, after he had lugged off 30 different toads, by count, all at once the idea suggested itself that it was a little singular that there should be so many toads possessing such *marked family resemblance*. Thereupon he took No. 30, and marked him with white paint, for identification. He was consigned to the waters of the river as all his predecessors had been. What do you think? No. 31 was painted and decorated. I do not know what he did—at least I do not remember—with No. 31, but there were not any more toads around that particular beehive after that. You can figure out the moral yourself. Either put bee-hives up on posts, as friend B. has done, or else see that they (the toads) do not travel back during the night.

Almost every visit I made showed me not only model apiaries, but model appliances for poultry.

Friend B. has no boys, but quite a family of girls, and they and their mother look after their chickens. It is no strange thing in Florida to see hens with 15 chickens apiece of their own hatching; and where the *women-folks* have charge of them they generally raise the whole brood. But every thing in the poultry line has to be carefully shut up nights.

Away up north, when we heard people talk of Manatee we imagined it was a big city. I was somewhat surprised, therefore, to find it only a little village. Why, the great county of Manatee contains only about 3000 inhabitants, and so it is with many other counties of large area. You can readily understand, therefore, why they do not have graveled roads, expensive bridges, schools, churches, and other things. In our trips around the country we passed by a colored church, and I began making inquiries about the people and their religion. Poultry brings a high price in Florida—the colored people, a good many of them, paying as high as a dollar apiece for them. You know how naturally colored people take to chickens. Well, this colored church got in debt. In fact, a mortgage hung over it. To raise the mortgage they commenced having “chicken-festivals.” The church people would go to a chicken-festival, but they *wouldn't* put their hands into their pockets to lift the mortgage, and so they kept buying chickens of friend B. in order that the mortgage might be raised. Do you know how it turned out? They did not get the mortgage raised, but they did eat up the chickens, and had them, the chickens, to pay for besides the mortgage. Just now it occurs to me that I have heard of white people managing church debts something after that same fashion.

To this end was I born, and for this cause came I into the world, that I should bear witness unto the truth. Every one that is of the truth heareth my voice.—JOHN 18:37.

These words are quoted only by that beloved disciple, John, the faithful and intrepid follower—the one who kept nearest to Jesus during that terrible time that shook men's faith—the time of the mock trial and crucifixion of the Savior. Jesus spoke these words while alone with Pilate. The latter asked Jesus, you will remember, whether there was any truth in what these people were saying. “Art thou a king, then?” Then comes the wonderful answer: “To this end was I born.” The great purpose for which God gave his only begotten Son to humanity—the principal reason why he sent him down to earth to battle alone single-handed with the wickedness of humanity, was that he should bear witness unto the truth. Sometimes people say, when sorely provoked by the shortcomings of humanity, “There is not any *truth* anywhere.” And Pilate replied, perhaps in sarcasm, perhaps in sorrow, “What is *truth*?” My impression is, that Pilate had become so accustomed to *untruth*—he was so familiar with fraud, dishonesty, deceit, treachery, and *crime*, that it seemed almost a sarcastic joke, as we would say in common parlance, to talk about *truth*. I think Pilate was satisfied, however, that for once in his life he had met at least one human being—one individual

—who *was* honest and true. He goes back to the Jews and says to them, “I find in him no fault at all.” In the other gospels we are told also that Pilate seemed to recognize the whole thing as a farce, and a piece of Jewish spite and jealousy; for they had not succeeded in raising even a shadow of any reasonable excuse for fault-finding; yet they *hated* him all the more. Were there no good people in the world at that time? Oh, yes! but Judas and his band had planned to have this whole thing hatched up and carried out when the honest and true friends of the Savior were sleeping. The high-priests and their followers feared the multitudes, so they arranged their plan to have their mock trial when none of his friends were around—in fact, when no honest people were near. They hated the truth, and did not want it to come out. They were determined to crucify him *because* they knew he would speak the truth fearlessly and honestly. Their selfish, greedy schemes could not prosper while he was around; therefore the cry was, “Put him *down* and *crucify* him.” They did not want truth. They *feared* the truth. They loved darkness because their ways were evil, and *he* was the light of the world.

Oh dear me! if this were true only of the wicked and greedy high-priests of *olden* times, it would not be so bad; if only those who profess to be the chosen servants of God and of the Christian religion lived in olden time, and olden time *only*, we might console ourselves with the thought that the world is growing better, and we might take things easy, and not worry ourselves.

On page 276 of our issue for April 1, I mentioned, at the close of my talk, visiting the spiritualist camp-meeting at Lake Helen; and I mentioned that it seemed as if I were thrown there providentially. I did consider, at the time that Home Paper was written, mentioning some things that I heard rather than any thing that I *saw* that was not so pleasant; but I decided then to finish my chapter that day by speaking only of the *good* and not of the evil. A circumstance, however, has opened the way for me to say things that perhaps I *ought* to say.

I told you I employed a livery-team to take me five or six miles. The driver and I naturally discussed this camp-meeting. I can not at this late date remember exactly the words of this conversation, but it was something to the effect that he had attended one or two of the meetings. Once a week—Saturday night, if I remember correctly—they held a “seance,” if that is the right name for it, where the spirits not only wrote on slates, played on instruments, operated telegraphic machines, etc., but the faces of the dead appeared to the audience, and the departed ones conversed with their friends, shook hands, etc. The young man told me the admission fee was \$1.00.

“Why, my friend, are there people around here who can afford to pay a dollar to see things of this kind, especially after the terrible losses around here by the freeze, and the general widespread feeling of poverty, etc.?”

He assured me they did come in great numbers. In fact, he said it was a great place for *boys and girls* to visit. Somebody has told me since that they charged \$2.00 admission for each person. Never mind—it does not matter particularly. I asked him if the exhibition was made in the daytime.

“Oh, no! always in the night, and in a private tent.”

I turned, and looked him full in the face.

“Do you believe in the things that you saw? Were you convinced that these wonderful things were really miracles, and that they were the work of departed spirits?”

"Why, no; I do not believe there are any spirits about it, nor any thing miraculous, and I do not much believe the crowd did, although, of course, we could not explain things, nor understand how it could be done."

While I was at the meeting, a very bright and intelligent woman told me they were having wonderful miracles performed. If I remember correctly, she said she saw the face of her mother, who died years ago, as plainly as she saw my face, and talked with her. I could not well manage to stay quite an hour, and so, of course, there was no time for me to remonstrate or hold any argument. I did, however, object to the large admittance fee charged, but was told that "the laborer is worthy of his hire;" that they could not afford to travel about and give these exhibitions, which entailed considerable expense, without pay. How many times the little text has been quoted as an excuse for extortion and fraud! Again, I asked why those slates, instead of being screwed together, and put away until such a time as the spirits were willing, could not have been hung outside, on the side of the tent, in the broad daylight of noontime; and why not let as many gather around as could be collected from the surrounding country? and while thus exposed to full view, if the spirits were desirous of communicating with friends on earth, why not have this mysterious writing appear in the full light of day? If there were good reasons why their forms should be visible only at stated times, I could not see why the *writing* could not be done in sight as well as out of sight. I did not feel then that it was my province to criticise severely, or to find fault; but I threw out these remarks in a kindly, charitable spirit. They spoke of the miracles—wonderful miracles—that were being performed. Our Savior performed all of his miracles among crowds, and mostly in the open air, *free of charge*, and in broad daylight; and, in fact, he said to his accusers, "In secret have I done nothing." And there was not a single witness who could show where even for one brief minute he did *any thing* secretly. His life was *truth*, and there was no sort of reason for secrecy.

I had a few minutes to wait for the train. The conversation around the depot was, of course, in regard to the wonderful developments at the camp-grounds on the shores of beautiful Lake Helen. A boy in his teens said he had attended all their exhibitions. I do not know where he got his dollars, but he must have scraped them up in some way. He, too, said he could not understand how the things were done; but when I asked him if he believed it was the work of spirits he looked me over as if he thought I must be a stranger, or something more, and replied, "*Spir-its! not much!*"

When I sat in the tent I looked over the audience, the speakers, and the singers on the platform. The whole matter was of the deepest interest to me. Perhaps I never weighed individuals and studied faces as I did then. When I furnished the text for the speaker, "Thou has loved righteousness and hated iniquity," I was looking from one to the other, and wondering, "Does that fine-looking woman honestly believe she is helping the cause of righteousness? or can it be possible that she is one of the party who love iniquity? God forbid." I looked at the young girls who assisted in the music; surely *they* were honest and sincere; and then I looked at the men—gray-headed men—men of culture, experience, and possessed of a certain kind of power to move people by their eloquence. Are *they* parties to the iniquitous part of this work? I felt sure there was iniquity. It could not be otherwise. Not my own wisdom nor that of any other hu-

man being could draw the line through that congregation of people. But God himself knew. The great Judge of all the earth, who reads our hearts, knew just what part of that audience were scheming and planning and *loving iniquity*. Let us drop the curtain here, and let God decide.

Some little time after my return from Florida, friend Detwiler, known more or less to the readers of GLEANINGS, wrote me, inclosing a clipping from a Florida paper, exposing the party who drew the crowds at Lake Helen. He invited them to his home. They were furnished every convenience, and went through with the same program as at Lake Helen; thereupon friend D., with others present, conjointly and publicly advertised them as frauds and humbugs. A little later he sent me a full *expose* from another locality. As it seems wise to give these people some publicity to induce them to stop their work, we give the clipping in full:

OKLAHOMA CITY, O. T., Mar. 20, 1895.

EDITOR NEWS:—Yesterday a Mr. Goodrich, a former resident of Florida, handed me a copy of your paper bearing date of March 8, and called my attention to the "doings" of one Concannon, a pretended medium. That you might be informed of his escape here I hurriedly write your paper.

Mr. Concannon came to our city. He followed two women, who preceded him two or three weeks and quietly learned the "lay of the ground," and became acquainted with as many of our people as possible. The confederate learned who had lost children, how they died, and causes of death; also cases of deaths of grown people, especially those who left children behind them to mourn their loss. When Concannon appeared, quiet meetings were held among the element who desired most to see spirits. Gradually, as became known of his presence, his audiences increased, and the personnel of the meetings changed. The manifestations were good, and, to the credulous, unexplainable.

Knowing the "manifestations" to be "snides," and our people duped, a few of us set about to expose the fraud, and did so the first meeting we attended.

Concannon would put his feet into a pan of flour, take rice in his hand, and then have his coat-sleeves sewed to his pant-legs at the knees, and coat-collar sewed up. Once in this condition, the curtains concealing him from the audience would close, and singing and other music commenced to allay or entice the spirits.

Myself with one other attendant took matches along, and arranged that one should seize the "ghost" and the other strike a match and examine the "critter." Fortunately the medium wanted to converse with me about some matters, and I was called to the curtain. The lady with him took me by the hands and the spirit (?) appeared. When the position was favorable I seized hold of the "ghost," and, lo and behold it was Concannon—nude—mosquito-netting around him for "angel wings."

The exposure was complete. We had him, examined the pan of flour his clothing, the rice carefully laid away, and the clothes used to wipe the flour from his feet. Also some of the committee witnessed him as he donned his clothes and sewed up. He can slip into and out of his clothes in half a minute. The trick is easily exposed—is raw—and one of the greatest frauds ever perpetrated on a public. When Concannon was caught, the women fought like she-tigers. If they are still in your State, attend the meetings again; and when Concannon appears at the parting of the curtains, jump forward and seize the fellow.

A little paint would not hurt, for there is no more villainous occupation than trifling with the subject as he is.

D. C. LEWIS.

Along with the above, friend D. makes some comments of his own, and bids me make any extract I think proper. Want of space compels me to quote only half a dozen lines that make a most excellent summing-up of the whole matter.

The question arises, which horn of the dilemma the camp-meeting management will accept—that of being deceived for five weeks, or that of being a party to the deception—both very humiliating and annoying, no doubt.

J. Y. DETWILER.

New Smyrna, Fla., Apr. 11.

The great wonder to me is, that any intelligent audience should consent to sit still and see a man go through such absurdly ridiculous things as putting his feet into a pan of flour and filling his hands with rice, sewing up his pant-legs, etc. I know they did that at Lake Helen, because it was mentioned to me several times as proof that the medium could have had nothing to do with the manifestations. Are we to suppose that the spirits of the departed would indorse such proceedings in order that they might communicate with the present age? Why, it is a miserably wicked slur on our an-

cestors. What does *possess* people to shut their eyes and ears to sense and reason?

Well, friends, there seems to be a better day dawning. On every hand we see truth rising up out of the dust and ashes, and asserting itself. It is not only in our great cities that the confiding people have refused to be humbugged any longer by sneaks and traitors, but a general movement seems to be inaugurated to look *into* things and after *people*. Just now I find something in the *Practical Farmer*, right in line. Here it is:

Enos Harnden, seed-buyer for the Department of Agriculture, will soon make a report regarding sales of seeds by members of Congress. It will involve well-known men in a mess of petty crookedness. He has discovered that the seeds annually given members for free distribution among their constituents have been sold by many members. Harnden even bought some himself. For \$75 he bought of a member 14,950 packages of vegetable seeds 1365 packages of flower seeds, and 82 packages of field seeds. These seeds actually cost the government \$228, so that the member displayed a remarkable ignorance of their value. Mr. Harnden, while he was in the detective business for the Department, refused to buy more than 100,000 packages of seeds which had been paid for by the government, and given to members free, and were offered by them for sale. It is quite possible that, when this report is presented, it will put a stop to the free seed business altogether. The thing was started to enable farmers to secure new varieties of vegetables and grains, and thus enrich the agricultural products of the country. Last year \$160,000 was appropriated for the purchase of these seeds to be given to members of Congress, in quotas of 15,000 packages each, and in turn to be distributed by them among their constituents. But the custom has been so abused that it will probably be stopped altogether. No good has ever come of it that any one has seen.—*Chicago Times-Herald*, April 23.

It seems to me the thing to do is to come right out in print with the names of these members of Congress. If our American people, in their blind zeal for party, have put men into office who will steal packages of flower and vegetable seeds given them to distribute among the rural people, let them be shown up. Let them explain, of course, if there is any thing to explain. But has not this thing been going on about long enough? It kept coming to my mind, however, that our good friend Harnden might *also* have been swindled when he paid \$75 for over 16,000 packages of government seed, even if the government did actually pay \$228 for them.

We are greatly pleased to find in the *Rural New-Yorker* of May 4 an editorial which backs up with their characteristic energy all I have said about Electropoise. It is refreshing indeed to see a journal of such age, standing, and influence, lend a helping hand.

Now please bear with me, friends, while I make just one more application. The proprietors of Electropoise and Oxydonor are still running things with a high hand, with the aid of ministers of the gospel and our religious periodicals. They do not want truth. They have laid their plans on the assumption that investigation will not be made. It brings vividly to mind a part of a verse in the 28th chapter of Isaiah. "We have made lies our refuge, and under falsehood have we hid ourselves." They have humbugged a certain class of ministers and a few so-called professors, and they are becoming boastful, even while they laugh in their sleeves at the success of their treachery. Publishers of our religious newspapers do not want the truth, because the truth would stop their money-getting. This is hard and severe, friends, I know; but it is a terrible thing to be permitted to go on. One of our prominent religious newspapers—one that especially exhorts to *holiness* and *sanctification*, wrote me that it was not their business to in-

quire into the scientific claims of Electropoise. They do not want to inquire. The truth would cost them money. I asked permission to publish the letter they wrote to me defending their course. Permission has not yet been granted. They dare not grant it. They are obliged to shut their eyes to the scientific part of it, or else they could not consistently keep accepting the advertisement. Let the truth come out, just as it did under friend Detwiler's keen scrutiny at that spiritual seance. Let the truth come out, and be held up to the light of day as it is being brought out in the government seed business. Let the truth and the full facts in the case be held up to the public gaze as Parkhurst has been holding it up. And now let the truth come out and be held up with Electropoise and Oxydonor in the same way. If I am mistaken, and they have some truth somewhere on their side, it will do them good and not harm. "Ye shall know the truth, and the truth shall make you free."

LATEST FROM ELECTROPOISE.

It seems these people exhibit a tendency to abandon their fraudulent science, and come a little nearer telling the truth. We judge so from the following, which we take from one of their advertisements in the *Christian Herald* of May 8.

"It puts the body into such a condition as to be able to absorb oxygen more freely through the lungs and also through the pores as well. It is thermal electricity. These are our theories about it."

I would call attention to the closing—"These are our theories." This would seem to indicate that they do not exactly know *why* it cures folks. If a chemist or electrician should prove to them that there is no electricity about it whatever, I suppose they would be obliged to say they did not know *what* it was that performed the cures. I should like to ask them a few more questions. For instance: If you do not know what it is, why have you any reason to think it has any thing to do with oxygen? Secondly, what reason have you for putting sulphur and plumbago into that little metal case? What good does it do? To be honest, they would have to say again, "We don't know." Third, why do you demand \$25.00 for what costs you but little more than 25 cents? I do not think they will say they "don't know" this time, for they *do* know only too well. And now I submit the facts in the case to the people who claim to be cured. Do you believe that putting sulphur and plumbago into that little metal case, and dropping the case into a bowl of water, cured your ailments when even the men who make it must admit they have no reason for so doing? We once heard of a colored doctor who gave a patient, in case of an accident, some lead shot and some rosin. When the regular physician came, and demanded of the darkey why he had administered such a dose as that, the explanation was that he was pretty sure something "was broke inside." The lead was to solder up the break, and the rosin was to make the solder *stick*. Now, this poor unlettered friend had some reason and sense to back his proceedings. Can the Electropoise people give as much of a reason? And yet they talk about the human body being "polarized," "taking oxygen from the air," etc.

There are some testimonials that it seems do not get into print in the Electropoise advertisements. Here is one of them:

Mr. Root:—I have had the pleasure of receiving and reading a copy (April) of GLEANINGS. It is in regard to your article, "Our Religious Literature

and Electropoise," that I now address you. This subject is important to me, for two members of my family have been intense sufferers from chronic rheumatism; and when one sees his friends suffering he will make great sacrifices for them.

My uncle has rheumatism—can not walk a step. All winter he used the Electropoise, and received no benefit from it. It is true, we rented it; but if we had been more flush in money matters we would have bought it. Our physician brought it to us saying he had no faith in it, because it professed to cure too much. But another physician, Dr. Buck, of Leetown, W. Va., had been using it with varying success. One of the worst features about the whole thing is, they recommend it for the most dangerous and rapid diseases, and ask you to not take any sort of medicine while using it. I take the New York *Churchman*, M. H. Mallory & Co., 47 Lafayette Place, New York, and it has whole pages of advertisements, praising and recommending the Electropoise. I also take *Munsey's Magazine*, and the May number has two whole pages devoted to Electropoise. The address is Frank A. Munsey, 151 Fifth Ave., New York.

If you please, I should like three copies of GLEANINGS and a few slips to send to those two publications.

MRS. W. H. SEIBERT.

Kerneysville, W. Va., May 20.

If it is indeed true that our regular physicians are recommending, or even suggesting, to their patients that *charms* and *baubles* may cure disease, things are getting to a rather bad pass, especially when they recommend such a trap for chronic rheumatism. I would inform our good friend that both the *Churchman* and *Munsey* have been warned again and again of the fraud they are helping to push, and yet they keep on. By the way, our readers may not know that the instrument (?) is rented out at \$15 for three months. Just think of it—\$5 *per month* for a senseless trap that does not cost half a dollar in the first place! What are we coming to? I stated this plainly to the editor of a prominent religious paper; and his defense was, that people nowadays are getting great profits for almost every thing. Great profits indeed! How about the farmers, market-gardeners, fruit-growers, and other people? Besides, what would be the effect on the rising generation to let them see instances, right before their eyes, where people who stand high are getting \$25 for what costs them but little more than 25 cts.? Yes, I know I have been going over this thing a good deal; but it will surely be the ruin of our nation if this and other work of a similar kind is not put down and stopped.

THE RECENT FROST.

In our last issue we spoke of covering our tomatoes with pie-plant leaves. Well, we have been doing this for almost two weeks. The tomatoes were all saved, but they look pretty sick on account of being covered up so much; and, even though they did not get frosted, they are a good deal stunted from the continued cold weather. We saved all the plants under glass, except that the frost was so severe tomato-plants were frozen where they came up against the glass. On Monday night, May 20, the frost was so severe that cabbages and cabbage-plants were more or less injured. It made me think of the gardens in Florida after the frost of Feb. 7; and when I saw the mulberry-tree in front of our back door, with the leaves and half-grown berries all cooked, it made me think still more of Florida. We all have to take our turn

with disasters and disappointments, sooner or later; but if we are working right along in harmony with the plans of the great God above, we may feel sure that adversity as well as prosperity comes from a kind and loving Father.

It is interesting to note what varieties of vegetables and fruits stand the frost best. While all of our common raspberries have been more or less injured, even before the fruit-buds were open, the buds of the Gault raspberry, even those down on the creek-bottom ground, seem to be uninjured. They are a little later than some of the others, which may account for a part of it; but the plant is certainly exceedingly hardy. We shall have no more plants for sale until next season.

Among the strawberries I was much surprised to see our old friend the Haverland loaded with green berries as usual, while nearly all the rest, both green berries and open blossoms, are dead and black. The Warfield comes next to the Haverland in this ability to withstand frost—at least, so it has seemed during this last frost. Our wax beans are all ruined except some that were not yet up. And here is a good reason for putting your early plantings in to a pretty good depth, and for putting in, also, a great plenty of seed. If the frost injures the first to get up, you still have the last. In Florida I noticed that those who had beans *almost* up were the gainers. You see they would be several days ahead of those who had to plant after the frost was over. Our early corn had also to be replanted—at least, we thought best to replant it.

As usual, a good many people borrowed trouble more than they needed to do. For instance, our apples are almost uninjured; a great part of the cherries still hang on the trees, and are growing larger every day, even though they do look brown and blistered; the same with plums to a certain extent; and this morning I found a *peach-tree* that had, by some hook or crook, got through, and the peaches looked as fresh as if there had been no frost at all. The tree was close to a building. Our grapes are all destroyed except some vines tacked on to the brick walls of our house. The wall is a protection; and, besides, it holds the heat during the night.

We are gathering beautiful strawberries, that were in our plant-beds, protected by glass. With a very little protection you can have them two weeks earlier, and absolutely safe from frost. In fact, the cloth covering for beds will protect strawberries perfectly. I feel pretty sure it will pay to grow strawberries protected by glass, say in February and March; by cloth in April, and in May if it should be needed. They will bring a much bigger price than the berries shipped from the South; and after you get your beds, sashes, and cloth covers, it is not so very much expense to keep them perfectly safe; and if you sell plants you can in this way have runners and new plants for sale during June and July, when nobody else is prepared to fill orders; and early plants put out in the above months will do wonders in the way of getting a stand for the next season. Of course, water should be handy where one plans to put out plants during these hot summer months.

MICHEL'S EARLY STRAWBERRY.

This has again given us our first picking to-day, May 28, and they have stood the frost almost if not quite as well as the Haverland. The berries are of a good size for an extra early, splendid color and shape, and exquisite in taste, only perhaps a little tart. If they bore as many berries as the Haverland they would be an acquisition indeed. The Haverland, with its great handfuls of berries on a single stem, will

be perhaps a week later. We have a few plants of the Rio. This is, perhaps, almost or quite as early as the Michel's Early, and it seems to be larger, and rather better in shape. We have not plants enough to decide whether it is as prolific as the Michel's Early or not. Every strawberry-patch should have at least a few of these extra earlies. Both are perfect blossoms.

ONION-PLANTS.

We are just now getting ready to fill an order for 200,000. The purchaser is satisfied to plant them out almost as late as June 1, because he did the same thing last year, and had excellent success. He lost his first planting by frost; but rather than lose the use of his ground, which was nicely prepared and heavily manured, he is going to purchase this large number of plants. In consideration of the quantity ordered, and the lateness of the season, we let him have them for 50 cts. per 1000. There is a moral right here. After you have been to great pains to get your ground fitted and heavily manured or fertilized, do not let it go to waste. Try to make it grow something of market value.

SCARLET CLOVER ABOUT JUNE 1.

□What do you think? Our first sowing of scarlet clover was in among raspberries. It was put in some time during the latter part of September. It did not come up very well, however, and this spring there were so many weeds and so little clover that we cultivated it all up. Yes, it was pretty well cultivated twice, and then the whole raspberry-patch was thoroughly hoed out. Yesterday, however, while I was going through the premises with our friend Hugh Vankirk, of Washington, Pa., one of the visitors suddenly stopped and remarked: "Why, what new sort of clover is that in there among those raspberries?"

I was a little way off, and told him I did not know of any new clover; but come to get a little nearer there were great stalks here and there among the canes, from one to two feet high, bursting out in great blooms of these wonderful crimson strawberry-like heads. Why, notwithstanding all our cultivating and hoeing, there was in some places almost a fair stand of crimson clover. Now, you see I am going to try this thing again; and I do not know but there would have been quite a stand on the creek bottom, if I had not been in so much haste to decide it was all killed, and plow it under. This raspberry-patch was the only place where the clover could have made a show, for all the rest was plowed under fully ten inches deep.

WINTER OR EGYPTIAN ONIONS; SOME QUESTIONS.

How early in the spring can you gather them for market? How long do they remain tender and in good condition for the table? Suppose you plant the sets August 1st, in what condition are they the first of the following April? To what extent (in numbers) do they multiply? How many of those "long succulent stalks" you mention does it require to make 1 lb.? What do you mean by saying in your seed catalog, that you "plant them three to five inches apart, in a drill, about as you would peas"? Is not that a long distance apart for planting peas? How large is the average set that you plant in the fall? TIMOTHY HALLETT.

Galena, Ill., Apr. 25.

We gather the onions for market as soon as the frost is out in the spring; but they are pretty small at first, and it takes a good many of them to make a bunch weighing four ounces; but they commence rapid growth almost the

first thing that starts. In order to have them early, the rows should be well mulched with coarse stable manure. This will keep the tops from freezing, and it also serves to bleach the long stalk, and keep it white and tender. We use them right along every day until, say, strawberry time. When strawberries are ripe the Egyptian onions begin to send up seed-stalks, and become rather tough and strong. So we commence on the American Pearl onions, which are now getting to be of the size of hens' eggs or larger. The best onions (Egyptian) for spring use are from the sets put out in July, August, or September. They do not multiply until they have produced sets. After that, when the sets are gathered, and the big seed-stalk is cut off, the original onion splits up into a dozen or twenty little onions. In order to get the best quality and best size, the ground needs to be exceedingly rich. The number of stalks required to make a pound depends upon the season. If you plant large-sized sets as soon as they can be gathered, say in July, in very rich ground, along in May they may be so large that four or five would make a bunch weighing a pound. In saying that we simply sprinkle the sets in a drill, and cover them up as we do peas, I meant to show you how little trouble it is to plant them, and not that we put the peas as far apart as we do the onions. The sets from these onions vary from the size of a grain of corn to pretty nearly the size of a small hen's-egg. The large sets make the biggest onions in the spring; but it would be rather expensive for seed, to plant only large ones. The best onions for market are those from sets the season before; but if you do not use them all for bunching, and let them stand to produce seed, they will grow a crop of seed right straight along, year after year; and you need not touch a hoe or cultivator to them unless you choose. You can keep all weeds down by heavy mulching with coarse stable manure, on the plan Terry manages his currants, gooseberries, blackberries, and raspberries. The old stalks, one or more years old, may be used for bunching, but they are not nearly as tender, neither do they have as much of an onion at the bottom as those from sets planted only the summer before. They continue to split up each season, however, as soon as the seed-stalks are mature and pulled away, so that a single row ultimately becomes a great mass of onions, sometimes two feet across, the stalks being as close together as they can stand. In such a row you can get an enormous crop of sets, but it needs constant and heavy manuring to maintain the size of these sets each year. In fact, so easily are the sets raised that there is money in them at a dollar a bushel. Permit me to say again, that, to keep up the reputation of these onions, you should use only those for market which were planted the season before, and grow them on *strong rich soil*.

GRAPE JUICE AS A MEDICINE.

On page 475 of last year's volume, after speaking about the remedial qualities of pineapples, I said, "I am told that grape juice, when properly canned up, just as expressed from the ripe fruit, makes a most healthful and nourishing beverage." The above was called to mind by a *present*—I think it came in a box of wax—two quart bottles of Niagara-grape juice. It came from C. J. Baldrige, of Kendaia, N. Y., and I want to tell you that the juice is exactly the same as that from the Niagara grapes themselves. Its appearance in the bottle is a beautiful transparent amber or straw color; and it is about the most delicious thing in the way of a beverage I ever got hold

of. I afterward learned from one of the book-keepers in our office that they had some grape juice from Concord last year, when the fruit was so cheap, and she kindly brought me some samples. With such a test as I was able to make, I am quite certain these pure fruit juices will many times cure sick-headache caused by indigestion, in the same way that pineapple does. The juice is put up without any sugar, and the cans or bottles are sealed up while hot, just as we put up canned fruit. With the frosts we have just been having, I do not suppose grapes will be offered this year at the very low prices they were last; but when any kind of fruit becomes a drug in the market, I think this is one of the ways in which it may be utilized by canning up the fresh juices. Friend B. sells it at \$4.00 per dozen quart bottles, and the bottles are worth 50 cts. a dozen when empty. You may say this is rather expensive as a beverage; but it is not at all expensive if used as medicine; and if our various churches have not already inaugurated the custom of using unfermented grape juice, they had, in my opinion, better do so, using the pure juice of the grape as I have described. Friend B. does quite a business, I am informed, in furnishing this product for communion purposes.

A NEW PLAN OF RELIEF BY WORK.

The above is the title of a little pamphlet by the Sterling Pub. Co., 106 Fulton St., New York. It gives in detail the result of the experiment made last season in Detroit in letting the poor have the use, free of charge, of the unoccupied land in the city. The ground was plowed, harrowed, and marked, ready for planting, then divided up into little garden-patches, and the poor of the city who had no gardens of their own were given the privilege, and shown how, to raise potatoes and other similar crops. The result, which has been widely published, was astonishing. About 430 acres were thus fitted and divided off into quarter-acre lots. About 3000 applications were made for land; but they were able to provide for only about 945 families. Let me quote:

The result is, that about a thousand families were enabled to pass through the winter without having recourse to the poor-commission, and a large sum was thus saved to the tax-payers.

The estimated value of the crops produced was from \$12,000 to \$14,000; although many families, from dire want, were compelled to dig up for consumption certain portions of the potatoes before they had attained any size.

Poor people almost fought for a chance to get a piece of ground to till; and those who were successful used their best efforts to obtain a full crop. Applications for land for 1896 were made by a great many of them. The loss by theft was practically nothing—certainly not more than that of the average market-gardener.

Well, friends, I confess this is good news—to me at least. That little book of mine, "What to Do," you may recollect, is right along in this line; and as the area of ground is small for each family, the ultimate result—that is, where people have grace and persistence to follow it up—will be "high-pressure gardening." Other cities are rapidly taking up the project; and just think of the general effect on the appearance of things. Why, I have again and again, in passing different cities in our land, felt pained to see these vacant lots—may be almost right in the heart of the city, some of them—growing great useless weeds; and where land is so high-priced and valuable, the contrast is really painful between such a lot and one nicely improved, no matter whether it is occupied by a store, dwelling, or some sort of factory, or a greenhouse. May God be praised for this new un-

dertaking. The city furnishes the *land*, you see, and the deserving poor people furnish the *labor*, and have the crop.

TOBACCO IN COLLEGES.

The effects of tobacco are beginning to be recognized by our schools and colleges. See the following:

Quite a sensation has been stirred in college circles at Delaware by the announcement of Dr. James W. Bashford, president of the Ohio Wesleyan University, that the question of the use of tobacco by the students had been carefully considered by the officers of the college, and concerning it he said: "Our faculty, after making a careful study of the matter, have decided to ask all our students to discontinue the use of tobacco, beginning next fall; and if any tobacco users come we shall have to dissolve partnership." This is a very radical step, as it is said that nearly 30 per cent of the students use tobacco. This new rule may affect the attendance next year.—*Ashtand Times*.

It is five years to-day since I read your article in GLEANINGS on the tobacco habit, and resolved to try to give up the weed. I am glad to say five years is gone, and *no tobacco* used by me since. H. C. HEDGES.

Lumberport, W. Va., Mar. 6.

I agree to quit the use of tobacco, and hope to get my pay in the shape of a smoker; and I will pay for it if I allow myself to be dominated by this vice again. P. E. AVILO.

Peñoles, Mexico.

Kind Words From Our Customers.

Your paper is a grand help on spiritual life to me, and is worth far more, as bee culture here is an uncertain calling. S. S. FETHEROLF, Palestine, O.

Thanks for the exposition of Oxydonor, as we have an agent here getting in his work on the despairing sick and aged invalids.

Lampasas, Tex.

R. A. HARDY.

MIXED JOURNALISM.

I wish to thank you for your articles on high-pressure gardening in GLEANINGS. They have proved a great help to me. To the teachings of yourself and Mr. Terry I owe much of my success in combining apiculture and potato-farming.

River Sioux, Ia., Mar. 11.

F. M. CRANE.

My wife says if GLEANINGS cost twice as much, and contained only A. I. Root's talks, she would take it. She, as well as myself, is somewhat partial to Rambler, as we have relatives and friends in and around Colton and San Bernardino. Somehow we both have "leanings" toward the Medina people, and can not get along and keep house and bees without GLEANINGS. The more men of A. I. Root's stamp there are in the world, the better. I wish every one could read his Talks. I can extract more solid comfort from one of his Talks than from any spread-eagle sermon I ever heard.

St. Joseph, Mich., Feb. 11.

E. A. MALLORY.

The raspberry-plant came to hand promptly, and such a nice plant—twice as large as I expected! It is a pleasure to send to you for any thing. I am sure to get as much as or more than I expect. Thanks for past favors.

N. A. E. ELLIS.

Rail, Mo., May 7.

[Now, friend E., don't be too sanguine. We happened to hit you just right on the raspberry-plant, and, in fact, that is the way we like to do business. But a great many times it is impossible to find the plants and other things to give our customers these happy surprises. Rich ground and plenty of care, however, go a great way toward doing it. Many thanks.—A. I. R.]

Still in the Lead!

BEGINNERS.

Beginners should have a copy of the Amateur Bee-keeper, a 70-page book by Prof. J. W. Rouse. Price 25 cents; if sent by mail, 28c. The little book and the Progressive Bee-keeper (a live progressive 28-page monthly journal) one year, 65c. Address any first-class dealer, or

LEAHY MFG. CO., HIGGINSVILLE, Mo.

In responding to this advertisement mention GLEANINGS.

CARLOAD SHIPMENTS.

Since our last report we have shipped a carload to Rocky Ford, Colo.; another to Joseph Nysewander, Des Moines, Ia.; a third car to F. A. Salisbury, Syracuse, N. Y.; and as we go to press we are loading the third car for Barteldes & Co., Denver, Colo.

LAWN-MOWERS.

It is not too late yet to invest in a lawn-mower to use in slicking up your front yard, and making the home grounds look neat and tidy. We call your attention to our line, and the unusually low prices, in our ad. on the third cover page of this number.

JAPANESE BUCKWHEAT.

We have a good stock of choice seed of Japanese buckwheat, and know where we can obtain more. Price, free on board cars here, bags included, 40 cts. per peck; 70c per $\frac{1}{2}$ bush.; \$1.20 per bush.; 2 bush., \$2.20; 10 bush., \$10.00; 40 bushels, f. o. b. Farragut, Pa., at 75 cts. per bush., bags included.

TYPE-WRITERS AT A BARGAIN.

Desiring to replace several of our Smith Premier type-writers by new ones of the same make, we offer for sale those now in use. They are all of the same age, and have been used here for only a little over two years, and work practically as well as when new. We will fit them all with new tympanis before sending them out, after which they will give the same impression as when new. The letters are not worn a particle. We will sell them for \$65.00 each, which is two-thirds of the first cost. Even with the constant use to which we subject them, we should expect them to work well for at least five years more; and for ordinary correspondence, nearly twice that. A new ribbon will be furnished with each. Sample work furnished on application, to intending buyers.

SPECIAL SECTIONS AT SPECIAL PRICES.

Our supply of old-stock sections is very nearly closed out. As there seemed to be no call for closed-top 7 to foot and $1\frac{1}{2}$, we have passed these under the cutter-head and made them open top and bottom, and we still have:

77,000	$4\frac{1}{2} \times 14 \times 1\frac{1}{2}$	open top and bottom, polished.
7,000	"	" x; to ft., open top and bottom.
3,000	"	" $x1\frac{1}{2}$ open top and bottom.
8,000	"	" $x1\frac{1}{2}$ open four sides.
12,000	"	" $x1\frac{1}{2}$ open four sides.
40,000	"	" $1\frac{1}{2}$ open top and bot'm, new cream.
20,000	"	" 2 open top and bottom, new cream.
20,000	"	" 2 open four sides, new cream.

Price, to close out, \$2.20 per 1000; 3000 for \$6.00; 5000 for \$9.00, or 10,000 for \$16.00. Special reduction in larger quantities, or to those who buy to sell again. We shall be glad to hear from any one who can use any of this stock. We desire to close it out before the season closes.

THE NEW BUSH LIMA BEANS.

We have made our bean-poles into kindling-wood, and never expect to want or use any more. The bush lima beans last season filled the bill so completely that the poles are ruled out, on our ranch at least. I believe the Burpee bush lima has given the best yield, as a rule; but the Kumerle is certainly the richest and most toothsome bean—in fact, I should place it at the head of all the bean family in delicacy and richness of flavor. We find we are likely to have quite a stock of these left over, and therefore we reduce the price as follows: $\frac{1}{2}$ pint, 10 cts.; pint, 18 cts.; quart, 30 cts.; $\frac{1}{2}$ peck, \$1.00. If wanted by mail, add 8 cts. per pint or 15 cts. per quart for postage. Remember, this is the bean for which I paid its weight in gold for a handful to plant, only a few years ago—\$75, in fact, for a small handful of beans. Now you can have half a peck for a dollar.

STOWELL'S EVERGREEN SWEET CORN.

Although this is not in our catalog, we are having so much demand for it we have placed it in stock, and can furnish it till further notice at 10 cts. per

quart, 75 cts. per peck, or \$2.75 per bushel. If wanted by mail, add 12 cts. per quart for postage. Our corn and beans have all been tested on our own grounds, and are now up and growing.

FIELD-PUMPKIN SEEDS, ETC.

There seems to be a general complaint that pumpkin seeds raised last year do not grow well. We can furnish you a good article for 25 cts. per lb.; small sugar pumpkins, especially for pies, 40 cts. If wanted by mail, add 9 cts. extra for postage and packing. Either kind can be pushed in among other crops that come off early, giving the vines the entire ground as soon as the early crop is out of the way. Give them good rich ground and plenty of sunshine, and you will have pumpkins in such plenty that the children can run all over the field, skipping from one great yellow fruit to the other, without touching the ground at all. Now is the time to put in the seed; and if you are too busy to attend to it, have the children push in the seed with their fingers, say every ten or twelve feet. Tell them to read this, and may be they will have more enthusiasm in doing the work good.

The month of June is the very best time to plant all kinds of beans. We have planted two acres of the Best of All green snap bean, and still have some seed left for any one who may want to help us provide seed beans for the friends down in Florida. For prices, see our last issue.

The first of June is also the best time to sow the seed for late cabbage. We can furnish Excelsior Flat Dutch, 15 cts. per oz.; \$1.50 per lb.

Our best cauliflowers are the very early or the very late. We seldom get nice heads in hot weather. Now is the time to sow the seed for the late crop, and we have nothing better than the Snowball.

Finally, the first of June is time enough to plant almost any thing in the whole seed-catalog, and still get a good crop if the weather is favorable. At the high prices that seed peas have been quoted for the last two or three years, there is money in raising them. If your seed has been treated with bisulphide of carbon, so that it contains no live bugs, you can grow a crop free of bugs, as a rule, in almost any locality. After sowing the seed, however, you want to keep watch of your peas; and just as soon as a single buggy pea is to be seen, treat your whole lot of seed until every bug, inside and outside, is as dead as a doornail. Just look at what seed peas are quoted in the seed-catalogs, our own among the rest—four or five dollars a bushel; and by taking pains you can raise just as good peas as anybody. Why in the world should we pay such prices for either American Wonder, Alaska, Premium Gem, or Stratagem?

FOUNTAIN SPRAYERS.

The time for applying poison to potato-vines and other small plants and shrubs is at hand, and you can use nothing more convenient for the purpose than a fountain knapsack sprayer. We can furnish the Myers, shown above, at \$3.25; 5 for \$13.00. We have also the Lenox, which works on the same principle, at \$3.00 each; 5 for \$12.00. We still have a good supply of barrel and bucket spray-pumps, ready to ship on short notice. See previous numbers for description and prices, or send for circular.

BEESWAX DECLINING.

The slips sent out in our catalogs this spring, headed "Beeswax Wanted," seem to have started the flood-tide our way, for it is simply a caution the way the wax has been coming to us the past two months. Although we use from 3 to 5 tons a month, it has been coming about as fast as we have used it, and we still have most of the stock bought in March, which we expected to have used up the past month. We don't mind having a good stock of wax, but dislike to lay in so much on a falling market. We decline the price we will pay, to 25c cash, 28c trade, with prospect of further decline in the near future.

SEND ON YOUR ORDERS.

As we go to press we have all orders filled, and are able to take a vacation Memorial Day with a clear conscience. There are, of course, a few received too late to get off on the last trains leaving, and no freight trains run on legal holidays. If you want any thing in a hurry which we can supply, let us hear from you and we will show you how promptly we can get the goods started. The crowd, when orders were delayed a few days, lasted only a short time; and it is doubtless due to the recent cold weather and frosts, and the consequent dropping-off of orders, as well as to our extra efforts, that we were able to catch up again.

WIRE NETTING; SHORT ROLLS AT FULL-ROLL PRICES OR LESS.

We have the following lot of wire netting of various sizes and widths in short or odd-length rolls. Very often a person wants a piece and can not buy it cut from a full roll without paying double price. You may be able to find in this list just what you need, or very near it. Even if you want more than a full roll you will find the prices at which we offer these to be in most cases less than full-roll price.

Of 2-inch mesh No. 19 wire, we have the following remnants and short rolls at $\frac{1}{2}$ c per square foot. The figures at the left give the width in inches, and the other figures give length of each piece in feet. Multiply this by the width in feet, then take one-half of the result to find the price of each piece.

18 | 138.
30 | 140, 144, 146, 148.
36 | 49 83, 83, 86, 90, 90, 92, 96, 96, 99, 100, 102, 116, 116, 118, 122, 124, 125,
129, 142.
48 | 83, 119, 122, 124, 125, 131, 134, 138, 138, 138, 140, 140, 143, 144, 144, 145,
145, 146.
54 | 52, 72, 88, 143.
60 | 120, 123, 127.
72 | 85, 85, 87, 100, 119, 123, 130, 138, 142, 144, 144.

Of 2-inch No. 20 we have the following pieces at one-half of a cent per square foot, less 10 per cent. Arrive at the price in precisely the same way as above, and take 10 per cent off.

30 | 129.
36 | 81, 88, 91, 102, 102, 103, 103, 109, 122, 126, 126, 128, 128, 136, 140, 141.
48 | 128, 144.
54 | 145.
60 | 139, 144.
72 | 139.

In the following list we give first the size of mesh; next, the number of wire; next, the width in inches; then the length in feet, and, finally, the price of the whole piece, so you will have no figuring to do.

2 in., No. 15, 18 in. x 75 ft., at 1.60; 18 in. x 74 ft. at \$1.55.
2 in., No. 15, 18 in. x 55 ft., at 1.20; 54 in. x 122 ft. at \$8.00.

1½ in., No. 19, 3½ ft. x 85 ft., at 2.00; 4 x 55 ft. a \$1.50.
4½ x 20 ft. at .60; 5 x 19 ft. at .65; 6 x 46 ft. at \$1.90.
1½ in., No. 18, 3 x 64 ft. at \$1.75.
1½ in., No. 16, 3 x 64 ft. at .35; 2½ x 70 ft. at \$3.00.
4 x 24 ft. at \$1.65; 6 x 102 ft. at \$6.10.

In lots of 5 pieces, any one or assorted kinds, deduct 5%; 10 pieces, 10%; 25 pieces or more, 15%. Better name a second or third choice, in case your first be gone. **The A. I. Root Co., Medina, O.**

MONEY-MAKERS

Are a strain of business Italians that winter in the cold North, and are ready for business, with a bushel of bees, when the flowers bloom. They are gentle and industrious. Queens warranted purely in June. Each, \$1.00; six, \$5.00; doz., \$9.00. Safe arrival and satisfaction guaranteed. Never had any disease.

Address **E. F. QUIGLEY, UNIONVILLE, MO.**

Best ~ Goods

At lowest prices are what we are all after. The *quality* of Cary's goods has never been questioned. His X X white thin foundation and polished one-piece sections are the finest on the market. His bees and queens are from the best strains, and reared and shipped in the way that long years of experience have shown to be the best.

He has the largest stock of **BEE-KEEPERS' SUPPLIES** in New England; and as to prices you have only to send for a catalog and compare them with those of other dealers.

To those living in the East, there is the still further consideration of low freight rates. Address

W. W. CARY,
COLRAIN, MASS.

In responding to this advertisement mention GLEANINGS.

If Tons of Honey,

Pleased Customers, and Increasing Trade is a criterion, then my queens are satisfactory. **Warranted** purely mated queens from 5-banded strain, 75c; six for \$4.00; dozen, \$7.50. Safe arrival and satisfaction guaranteed. Send for free circular.

J. B. CASE, Port Orange, Vol. Co., Fla.

Order your supplies early before the rush gets you. Send for our price list of Bee supplies and Fruit packages. Address

BERLIN FRUIT BOX CO.,
Berlin Heights,
Erie Co.,
Ohio.

NOTICE.

We have proven to our satisfaction that queens bred in the North produce bees that are **hardier** and **winter better** than those bred in the South. We make queen-rearing a specialty. We never saw foul brood or bee-paralysis. Send for our free descriptive price list of our Gray Carniolans and Golden Italians. Prices to suit the times.

F. A. LOCKHART & CO., Lake George, N. Y.

Crane Smoker 1895 Pattern.

This excellent smoker was introduced some two years ago, since which time it has worked itself rapidly into popular favor.

Patented March 12, 1895.

Its Distinctive Feature is the Crane Valve, by which the full force of the bellows is secured without waste, and by which also smoke is prevented absolutely from going into the bellows.

The Legs are of Skeleton Malleable Iron, contracted at the feet so as to be out of the way of the fingers in handling, and are secured to the bellows by bolts instead of screws.

The Shield is of Light Corrugated Tin, and bags next to the bellows, thus giving ample protection from heat.

The Cone Top easily tilts back for replenishing the smoker, and is secured by a malleable-iron hinge, the working parts of which are milled so as to insure accurate adjustment to the stove or cup.

As to Fuel, it will burn any thing, including Soft Coal, Stovewood, Planer-shavings; and it makes no difference how much the latter may be crammed down in the cup, there will be the same strong blast as before.

Price, 3½-inch barrel, \$1.85, post-paid; or \$1.50 by fgt. or exp.

The A. I. Root Company,
Medina, Ohio.

H·O·N·E·Y!

If we would be successful in the production of honey it is of vital importance that our queens be first class. After an extended experience with the different races of bees brought to this country, I am led to believe, all things considered, that these direct from Italy have never been improved upon. Large yellow prolific queens from imported mothers, mated to drones of imported stock from a different source, securing a direct cross. Untested, ready May 25, 75c; 6, \$4.25; 12 for \$8.00. Select untested, \$1.00. No disease.

L. H. ROBEY, Worthington, W. Va.

STEEL TANKS
We furnish steel tanks with covers, all galvanized after completion, in nests of ten, 8 to 12 feet high and 30 to 36 inches in diameter, at 2½c. per gallon. They do not rust, shrink, leak, give taste to water, nor allow foreign substances to get in. They can be put in garret or barn and thus are protected from freezing. They take no setting up, are cheaper than wood. Tank substructures of all sizes made to order. Send for price list and designs for substructure and ornamental water supply.
**AERMOTOR CO.
CHICAGO.**
2½ CTS PER GAL

Did you ever stop to think how completely the Aermotor Co. made the modern windmill business? How it has monopolized this entire line of manufacture because of its ideas, inventions, designs, qualities and prices, or forced others to be literal and servile imitators? Witness the steel wheel, the back geared pump, the high geared power mill, the steel towers, fixed and tilting, the galvanizing of work after completion, the grinder centrifugal feed, the improved irrigating and other pumps, the all steel pole saw—one of the most popular things we ever put out—the steel storage and storage tanks. Everything we have touched we have bettered and cheapened. It is the thing we have delighted in and it has paid. We have established a score of branch houses, so as to have all these goods near those who want them. The Aermotor Co. has but one more ambition. It wants to build and fill one more new building. It has 2 acres of land at its present location unoccupied by buildings. It expects to commence in June to cover that 2 acres with a single building, 7 stories high. This will give it 14 more acres of floor space. Then when the public demand requires more goods than can be produced with this added space, it will refuse to extend further, or make any effort. It will have done its share to supply that demand. It will then turn away all new comers. UNTIL THAT TIME IT EXPECTS TO CONTINUE TO SUPPLY THE WORLD WITH THE GREATER PART OF ITS WIND WHEELS, TOWERS, GRINDERS, FEED CUTTERS, PUMPS, STEEL FRAME BUZZ SAWS, STEEL STORAGE AND STOCK TANKS, STEEL SUBSTRUCTURES, ETC., ETC., GALVANIZED AFTER COMPLETION. IT WILL CONTINUE TO DEAL MOST LIBERALLY WITH THE PUBLIC, FURNISH REPAIRS AT A LOW PRICE, AND BE THE GREAT MODEL SQUARE-DEALING WIND POWER AND WATER SUPPLY HOUSE OF THE WORLD. **AERMOTOR CO., CHICAGO.**

HONEY COLUMN.

CITY MARKETS.

CLEVELAND.—*Honey.*—The honey market is not very brisk. No. 1 white 1-lb. sections are selling at 12; No. 2, 10. Extracted, amber, 5@6; white, 7@8. Beeswax, 26. Present stock cleaning up; no receipts to speak of.
June 8. WILLIAMS BROS.,
80 & 82 Broadway, Cleveland, O.

CINCINNATI.—*Honey.*—Demand is slow for comb honey at 12@16 for best white. There is a fair demand for extracted honey at 4@7. Beeswax is in good demand at 25@31 for good to choice yellow.
June 8. CHAS. F. MUTH & SON,
Cincinnati, O.

KANSAS CITY.—*Honey.*—Demand light, supply light. We quote No. 1 white comb, 13@14; No. 2, 12@13; No. 1 amber, 11@12; No. 2, 8@10. Extracted, white, 7; amber, 5@6. Beeswax, 22.
June 10. C. C. CLEMONS & Co.,
Kansas City, Mo.

BUFFALO.—*Honey.*—The honey market is exceedingly quiet. Fancy moves slowly at 12@13; choice, 10@11; buckwheat and commoner grades are moving at 7@8. Beeswax in light supply, and firm at 28@30. Extracted dull, and very little doing in honey at present.
June 8. BATTERSON & Co.,
Buffalo, N. Y.

DETROIT.—*Honey.*—Best white honey held at 13@14; few sales and little in stock. Dark grades dull at 10@11; Extracted, 6@7. Beeswax, 27@28; supply good.
June 9. M. H. HUNT,
Bell Branch, Mich.

CHICAGO.—*Honey.*—There is very little honey selling now, and prices are nominal. Best grades of white comb, 14; dark, 8@10; extracted, 5@7, according to quality, flavor, and package. Beeswax finds ready sale at 28@31.
June 8. R. A. BURNETT & Co.,
163 So. Water St., Chicago, Ill.

KANSAS CITY.—*Honey.*—The stock of comb honey is about all sold; very little on the market. One-lb. comb, white, 12@13; amber, 10@11; extracted, 6@6½; dark, 4½@5. Beeswax, 25.
June 10. HAMBLIN & BEARSS,
Kansas City, Mo.

MILWAUKEE.—*Honey.*—This market at present is very dull on all kinds and qualities, and values are almost nominal. The stock of section honey is fair for the season, and generally of good quality. Extracted stock small. We can quote choice 1-lb. sections, 14@15; good, 12@13; dark, 10@12. Extracted, white, in kegs and barrels, 7@7½; in pails, 7¼@8½; dark, in kegs and barrels, 4@5. Beeswax, 26@28.
June 4. A. V. BISHOP & Co.,
Milwaukee, Wis.

MINNEAPOLIS.—*Honey.*—Honey is ranging about as follows: Fancy white, 18; No. 1 white, 16; fancy amber, 15; No. 1 amber, 13; fancy dark, 12; No. 1 dark, 11. Extracted, white, 7@8; amber, 6@6½; dark, 5. Can you advise us where we can buy some strictly fancy white honey? We are about cleaned up on that grade of goods. Dark honey is very slow sale.
June 5. J. A. SHEA & Co.,
Minneapolis, Minn.

DENVER.—*Honey.*—Our market is well cleaned up in fancy comb honey in 1-lb. sections, still the prices remain about the same, as the market is supplied with old and granulated stock. No. 1 comb in 1-lb. sections, 10@11; No. 2 has no demand. Extracted, No. 1 white, in 6-lb. cans, 2 in a box, 6c. There is a better demand for extracted honey at this season, as the comb honey is nearly all granulated. Our dry climate is the cause of so much granulated honey in our market.
June 11. R. K. & J. C. FRISBEE,
Denver, Col.

PHILADELPHIA.—*Honey.*—New crop of honey has commenced to arrive in the market, but there is very little call for it as yet. Some few sales of fine white-clover comb at 13@14. Extracted is selling at 5½@6. Beeswax is declining; selling at 27@29, according to quality.
June 11. WM. A. SELSER,
No. 10 Vine St., Philadelphia, Pa.

BOSTON.—*Honey.*—Our market on honey remains the same, with very light demand. Prices for comb, 14; extracted, 5@6.
June 10. E. E. BLAKE & Co.,
Boston, Mass.

FOR SALE.—600 lbs. of comb honey, in 1-lb. sections, in 24-lb. shipping-cases, at 12c per lb.
EDW. SMITH, Carpenter, Madison Co., Ill.

BEE-KEEPERS.—We buy quantities best quality of comb and extracted honey. Let sample accompany price. We guarantee prompt pay, and give The A. I. Root Co. as reference.

J. A. BUCHANAN & SONS, Holliday's Cove, W. Va.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty.
J. P. IVY,
Secretary Bee-keepers' Association,
Phoenix, Maricopa Co., Arizona.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c.
OLIVER FOSTER, Las Animas, Col.

No. 1 extracted honey in 50-lb. pails at 7c per lb.—\$3.50.
J. B. MURRAY, Ada, O.

Black and Hybrid Queens For Sale.

I have 25 mismatched Italian queens for sale at 30 cts. each, or 4 for \$1.00. A good share of their bees are yellow.

ALBERT HINES,
Box 532, Independence, Ia.

Tested Queens by Return Mail at \$1.00.

I am devoting my apiary largely to the rearing of queens, making a specialty of tested Italian queens at \$1.00 each or six for \$5.00. These queens are of this year's rearing, and have been kept just long enough to know that they are good layers and purely mated. For several weeks I have been filling orders *by return mail*, and I am keeping a large number of queens in nuclei for the express purpose of enabling me to fill orders promptly. More than six queens (tested) will be sold at 75 cts. each, but such orders must be sent with the understanding that, while they will be filled as promptly as possible, it may not be by return mail, which will be the case with six or a less number of queens. The *Review* and one queen for \$1.50.

Vol. XXIII.

JUNE 15, 1895.

No. 12.

STRAY STRAWS

FROM DR. C. C. MILLER.

IS FAILURE to be our doom another year? June 4 white clover is in full bloom, but bees are doing nothing.

PLEASE KEEP WATCH, and tell us whether a queen prefers to lay in new or old comb; also, which the bees prefer to store in.

"GLEANER" gathers items "Among the Bee-papers" for *A. B. J.*, and, as might be expected, he gleans a good many gleanings from GLEANINGS.

"DO DUCKS eat bees?" is a question asked in *British B. J.* I don't know; but at one time in this country the bees were charged with eating ducks.

ADULTERATION of foundation is so bad that Prof. Foucart complains in *Le Progres Apicole* that nowadays he finds foundation that sags at 77° to 88° F.

EX-PRES. ABBOTT "roasts" ex-Secretary F. Benton, in *A. B. J.*, for not publishing report of St. Joe convention, after accepting \$25 in payment for his services.

THE THERMOMETER did not vary from 58° all winter in the cellar of O. E. Douglass, and his bees came out in splendid condition. But the cellar was well ventilated.

IN CUBA, according to H. G. Osborn, in *American Bee-keeper*, there are places where the honey is squeezed out and thrown away, the wax only being worth saving.

A NUMBER of cases, carefully observed by F. Goecken, showed young queens to be fecundated at from 8 to 10 days old, the first egg being laid 3 days later.—*Centralblatt*.

IN EAST AFRICA, says R. Ludwig, in Gravenhorst's *Illustrierte Bienenzeitung*, bees are kept chiefly for the sake of making out of the honey an intoxicating drink of disgusting taste.

I DON'T FEEL left out in the cold with my cellar stove so much as I did, since I know so good a man as H. R. Boardman is with me. Artifi-

cial heat may be a bad thing, but natural cold is worse.

TO MARK A HIVE temporarily, green grass or weeds will do nicely. It practically takes itself away, for next day it is withered, but a stone or block might be taken for a fresh mark the next day.

QUEENLESS COLONIES are often the result of a bee-keeper's handling. A queen is sometimes taken off with the cover, and once I found a queen on the hat of my assistant—a clipped queen too.

REV. E. T. ABBOTT, in *A. B. J.*, quotes Herbert Smith as saying that "particular parts of the body may become temporarily inoculated against insect stings." I wonder whether the inoculation is only local.

WOOD-BASE FOUNDATION reminds me of the foundation with tin-foil base that came out with a flourish years ago. It was a nice thing, only the bees would none of it. What have they said about the wood base?

"BUCKWHEAT, north of the latitude of North Carolina, may be a good forage-plant; but south it is perfectly unreliable. It will secrete an abundance of nectar only when the atmosphere is cool and moist. This is a condition we can not well have in the South."—Dr. J. P. H. Brown, in *A. B. J.*

DR. BROWN relates in *A. B. J.* that he gave goldenrod credit for being a good honey-plant, as bees worked on it more or less all day long, but afterward found that the honey stored came from aster that commenced yielding each day toward noon, and he concludes that goldenrod is a poor yielder with him.

I WAS SCARED a little when I got before such a big lot of railroad men in Chicago, but I found them a pretty nice lot. They seem to have hearts as well as other people. If a bee-keeper can be allowed to judge, I should put down J. T. Ripley, Chairman of Western Classification Committee, as a real gentleman.

LYSOL may prove to be the drug for foul brood, in Gravenhorst's opinion. It is cheap, and is more like crude than refined carbolic acid, and in his experience crude carbolic acid

has proved good as preventive and cure, while the refined article has been unsatisfactory. He thinks perhaps the coal tar that is in the crude, and also in lysol, may be important.

APIFUGE. In *Le Progres Apicole*, E. J. Roland recommends cantharides, or Spanish flies, and carbolic acid. Dissolve the powder in the acid, apply it to the skin, greatly diluted, and the bees won't sting there. Put the mixture full strength on a sponge and use it in a smoker if you want to drive bees out of a hive.

THE GREATEST GOOD to the greatest number would make a law that owners of cider-mills and such things should screen them against the intrusion of bees. If I am prevented by law from putting poisoned honey on my own ground to kill my neighbor's bees, equally I should be prevented from killing them with a cider-mill.

IF I HAD KNOWN Ernest was going to be under the weather I'd have tried hard to knock him out on the T-super question before he recovered his usual vigor. Guess I must try to fire off the few shots I have left, anyhow. [I am getting a little out from "under the weather," so you had better look a "leedle oud."—Ed.]

WHO CAN TELL what makes combs turn black as they grow old? It doesn't seem reasonable to believe the bees' feet do the coloring. [We know that bees go into the hive with dirty feet; and we know, too, that the cocoons and the deposits left from brood-rearing seem to have a darkening effect upon newly built combs along the line where the brood was. Is it not probable that both causes contribute toward the darkening you speak of?—Ed.]

"THE NORTH AMERICAN convention this year has received a special grant of \$100 from the Ontario Legislature, to defray the expenses at Toronto," says the *A. B. J.* Say; do you Canucks mean to own the convention? and will you reincorporate it? Joking aside, that's a grand stroke. [Yes, indeed that was a grand stroke; but our country is so large I am afraid we could not get similar favors at its hands—at least, not at present. I anticipate that the next North American will be the best in the history of the association. Those Canucks—beg pardon, Canadians—are hustlers in convention matters.—Ed.]

YOU'RE 'WAY OFF in thinking Stray Straws for June 1 are reposing in my coat-tails. My wife has searched my pockets thoroughly; and when a woman can't find anything in a man's pockets you may be sure there isn't any thing there. "Where are they, then?" I don't know. [I knew that you *once* carried Stray Straws in your pocket, and it was only when we punched you up just in time that we discovered their whereabouts. But you were then able to get them to us in time for the journal, so as not to break the chain. Yes, you are right. When a

woman can't find a thing in a man's pocket, no one can—not even the user of said pockets himself.—Ed.]

WILL AS MUCH BROOD be produced in a two-story hive as if the combs are all in one story? is one of the conundrums in *A. B. J.* Opinions are pretty well divided, with some preponderance in favor of the single story; but most of the repliers seem not to answer from experience. [I have noticed sometimes that the repliers, when we had a similar department in our own journal, frequently gave an off-hand opinion, and not one based on experience. At the risk of doing something nearly as bad myself, I will say that, from what little experience I have had, bees breed better all in one story than in two separate ones.—Ed].

FEEDERS.

PROPERLY AND IMPROPERLY CONSTRUCTED;
THE LOSS INCURRED FROM POOR FEEDERS.

By H. R. Boardman.

Would bee-keepers be benefited by my experience with feeders if I should give it, or would they go all over the ground for themselves? is a question I have asked myself more than once. Although I am satisfied that not all will be disposed to accept my notions, some seed may fall on good ground.

Success in feeding depends almost wholly upon the feeders used. A large amount of the feeding done, even by quite practical bee-men, results only in injury to the bees, instead of benefit, leaving out of the account the cost. This is not a very encouraging compliment, I will admit; but it is too true. Feeders must be so constructed that the bees can not possibly get daubed with the feed. You may say this is easy enough. I once thought so too; but it is not so easy a thing to accomplish.

The most common kinds of feeders are those with floats or slots. Take any of this class of feeders, or even combs filled with feed, which would seem, certainly in the latter case at least, to meet the requirements of the bees, and watch them in their mad scramble to get each a share. At first, when only a few are feeding, they poise themselves daintily and sip leisurely and carefully as though their own fine plumes and feathers were their sole care. Soon they gather faster; and as their numbers increase they begin to hurry and jostle against and run over each other. Still they gather until they are piled up on each other in a wild, struggling, excited mass, which is not truly represented by any thing except the board of trade of some great city.

Now, those at the bottom, which were at first

so careful and dainty of themselves, are pressed and crushed down into the feed; and as each bee makes its escape up through the struggling mass with its well-earned load of sweets, it wipes its feet and wings and body off upon its neighbor's fine clothes, and they in turn rub it off upon others, and this process is kept up until the whole mass becomes smeared and dauby.

What then? As if ashamed to be seen by their friends at home in this deplorable plight, they go out and alight on a twig or leaf, or on the grass or fence, and commence scraping off the precious sweet they were so eager to get into a few moments before, and wipe it upon any thing and every thing at hand. The loss of the feed thus wasted by being scattered around in almost imperceptible particles is a very serious loss to the bee-keeper when considered in the aggregate.

Nor is this the only serious part of the business. The whole apiary is thrown into a bedlam of commotion by the feed that has been so recklessly and profusely exposed by the daubed bees, and this is the explanation of how bees are so commonly excited to robbing and pilfering by feeding.

In my search after a feeder I have tried many—very many—of this class, and I could furnish now a rare collection of samples that have been consigned to the rubbish-gallery and to oblivion, that once were objects of great expectation. I had high hopes at one time in regard to open-air feeding, and I constructed an atmospheric feeder by inverting a can of feed on a slotted board. This worked admirably; but after feeding a few barrels of sugar in this way I abandoned the idea of open-air feeding, and used the feeders only for water in the dry part of the season. The objection to open-air feeding, according to my experience, was, the excitement caused too much waste of energy to make it profitable. The strong colonies, that had the least need of feed, got the lion's share. But the principle of this feeder I did not abandon. It became the stepping-stone and led to the atmospheric entrance-feeder, which has been already described and illustrated in this journal by the editor, and which is the only one I have ever been entirely satisfied with. In regard to it I will add to the brief description already given a few more words in detail.

I use a special wide-mouthed can holding two quarts, and not a common fruit-can, as described. I would not recommend any thing smaller. It would involve more labor in feeding. I have found these small enough. In using these feeders no feed need be exposed, either by the bees or the bee-keeper, to attract robbers. The feed is in sight, and the bee-keeper can see at a glance just what each colony is doing, and know just when the feed is out, without any examination. The feed is perfectly protected, and no harm can come to it from storms, even if it remains unused indefinitely. They are as near

being robber-proof as any feeder can be made. They are always in working order, but will not work without the assistance of the bees, even if left on all summer. Last summer I was feeding at one time 145 colonies in my home yard, and 60 more at my out-apiary.

HOW IT WAS DONE.

The cans were filled in the bee-house, from a tank, by a faucet, the caps adjusted, and placed in crates holding 12 to 14 cans. These were placed on a wheelbarrow, when ready to feed, two crates at a load, and wheeled out into the yard, and distributed by placing one on top of each hive. When all are thus distributed I pass rapidly along and invert each can in the feed-chamber, which has been previously adjusted to the hive. The bees are protected from injury in this chamber by an ample bee-space below the can when adjusted. I have filled these cans at all times, whenever they became empty, but prefer feeding at evening.

In feeding my out-apiary I took a sufficient number of these cases of filled feeders into my spring bee-wagon and drove to the apiary, with no stopping or spilling; thus the work of filling was all done at the bee-house at home, where the feed was prepared.

I prepare the feed by dissolving granulated sugar in water, nearly equal parts of each. I use hot water, but cold water will do, I am sure. Sugar syrup needs no doctoring for feed, excepting what the bees do themselves.

East Townsend, O.

[There are many things in favor of an entrance feeder, and such feeders would have been used more largely in the past but for the fact that none have been constructed hitherto but that would more or less invite the attention of robbers. But from what I saw in Mr. Boardman's yard during the robbing season last year, I am firmly of the opinion that he has solved the problem. Furthermore, his feeder may be used as a percolator, if desired, I think. Indeed, he almost admits as much when he says the sugar and water may be mixed half and half, the water cold; and even if the sugar did not all dissolve, more water could be put in at the next feed, and the bees would thus take care of the whole.—ED.]

WAX.

ADULTERATION, AND HOW TO DETECT IT.

By Karl Rudolph Matthey.

The adulteration of wax is due mostly to its high price; and this is done as well with the natural yellow wax as with the bleached product. This adulteration is effected either by means of other fats such as tallow and stearine, and sebatic acid, or with vegetable fats and various kinds of vegetable wax; and lately with refined ozokerite (mineral wax, earth wax, or ceresin), and then rendered hard with certain solid substances. One may therefore safely conclude that adulteration of less than 30 or 40 per cent is seldom or never met, and some with

40 or 50 per cent, and some even very much more. In buying wax, therefore, it is necessary to be on one's guard; and it is always to be recommended that the specific gravity and the melting-point of wax be carefully determined when testing the quality of it.

The following is a test to determine whether foundation is made of pure wax. When, in making foundation, a mixture of beeswax and ceresin is encountered, the detection of the adulteration is a very simple matter—namely, by bleaching. As ceresin can not be bleached by the sun's rays, but must be bleached by the use of chemicals, foundation to which ceresin has been added will remain more or less of a yellow color when exposed to the light of the sun; while cells made of pure beeswax, if hung in the full light of the sun for a few days, and occasionally sprinkled with water, will become perfectly white.

ANOTHER TEST.

Melt a small piece of foundation in a vessel, being very careful not to burn it. At the same time, take a few tablespoonfuls of water and add thereto a little soda. Pour the melted wax into the soda water. After the mixture has been stirred for a while the wax will become perfectly soapy; if, however, ceresin was in the wax, the mixture does not become soapy, but swims on the surface like an oily mass.

It has been proven that many makers of foundation do not use the required amount of pure wax, but adulterate it with one-half or even two-thirds of ceresin*.

Material and shape must have especial attention in making foundation. In making it, only absolutely pure wax should be used. Any admixture of foreign substances debases the product. For the bee-keeper it is also of the greatest moment to be able to test the purity of his foundation before putting it into the hives. The most satisfactory conclusions in this matter give the specific gravity of pure beeswax as .966, and the melting-point at 143 to 146°. All adulterants, such as stearine, suet, ceresin, paraffine, mineral wax, spermaceti, etc., differ from each other in these two respects. Make a mixture of water and alcohol, of such density as will permit pure beeswax to float—that is, so it will not touch the bottom of the vessel nor yet come to the surface. Into this drop a piece of the foundation to be tested. This must maintain itself in the mixture at the same height the wax does.

Wax is found varying in color from white to black; and to the same degree the odor varies also, according to the plant from which the honey was mostly derived; hence when a bee-keeper compares the color and odor of Turkish, Indian, African, and other kinds of wax, with his own, he will nearly always make a mistake.

That foundation made of pure wax can be

stretched but slightly (if any) is entirely false. Pure wax expands in a warm temperature very noticeably. The resistance which wax offers to a direct pull, at the same temperature, varies within very narrow limits; hence it does not depend altogether on the country the wax came from, but on the season of the year, and even on the source from which it comes. It would take too long for one to examine all of its peculiarities. There are different kinds of entirely pure wax which would be quite unfit for foundation, as they lack the necessary toughness. Certain it is, that foundation of pure wax, whatever the color and smell may be, is always worked out by the bees willingly and rapidly.

WHAT IS CERESIN?

I take my answer from a pamphlet written by Fried. Thalmann, entitled "Fats and Oils."

"Under the name of earth wax, or ceresin, there has been put on the market within a short time, in large quantities, a product which has received the name of wax on account of certain physical peculiarities which it has in common with other kinds of wax. Earth wax is, however, a mineral substance, and is related to petroleum. Good clean mineral wax is easily mistaken for beeswax, and actually forms a large part of the 'wax' of which candles are made, and sometimes the entire part. When the price of beeswax is much higher than that of mineral wax, it is a gross deception to call a mixture of the two by the name of 'wax;' and this fraud can be detected only by careful experiment, determination of the melting-point, the specific gravity, and other peculiarities."

CERESIN FOUNDATION.

I reproduce the following, simply to show that foundation made from ceresin is publicly sold in Germany:

The undersigned firm offer ceresin foundation in their price list, together with that made from pure wax, on the following grounds:

1. The amount of beeswax produced, when compared with that of honey, is very insignificant, being scarcely 5 per cent of the latter.

2. The cheaper foundation made of ceresin, whether the extractor be used or not, and be the honey harvest never so good, is decidedly conducive to an increase in the net amount of honey produced as compared with the use of foundation made of pure beeswax.

3. The price of beeswax must fall more and more—that is, come nearer to that of ceresin, and that is only a question of time—or else the use of ceresin and other kinds of wax will become more and more common. But if it does become cheaper, then the use of ceresin for foundation will be discontinued.

4. No man, either officer of the law or a private citizen, can control or hinder any one of the thousands of bee-keepers of Austro-Hungary in the use of ceresin foundation, whenever and wherever he pleases, whether it be made by means of a plaster-Paris or wax mold.

BARON ROTHSCHUETZ.

Weixelburg, Austria.

[This article is interesting and valuable; but I feel sure no American manufacturer would think of making adulterated foundation.—Ed.]

* This certainly does not apply to this country.—Ed.

RAMBLE NO. 134.

BLOCKSBURGH.

By Rambler.

We divided our deer meat with our friend the blacksmith who had so kindly allowed us the use of his corral. He did not enthuse much, however, over deer meat. He said his boy could shoot one almost any day. Our blacksmith wielded his hammer, chewed plug tobacco, and discussed the tariff on wool, in his shop in Harris. When we passed through Harris we found the blacksmith's shop the only place of business there, and, of course, our smith was an important personage. We lifted our hats to him as we passed, and he returned our salutation by coming to the door and expectorating a quantity of tobacco-juice. He wiped his mustache with the back of his hand, and returned to the duty of pounding his anvil.

We rushed down some long steep grades, and made good time. Eel River, a fine mountain stream, we crossed here. Bro. Pryal wanted to stop and fish again. It was truly wonderful how the sight of a stream of water would stir up all of the piscatorial elements of his composition. We hastened across the long bridge; and Susan B., losing sight of us, set the whole valley vibrating with her neighing; and the series of bites Bro. Pryal wished so fondly to indulge in were lost. Our dog Jack was an object of sympathy these days. The hot sands of the road made him footsore; and on the long stretches of mountain travel, where we could find no water, he learned to look up to us for a drink from our canteen, and he became quite expert in the exercise of drinking from it.

We made another forced drive after crossing Eel River, and after dark entered the little town of Blocksburgh. This time the shoemaker came to our rescue and provided a camp in the suburbs of the town, near a pure, sweet, cold-water spring, which fountain of water was the making of the town. Blocksburgh is a town of about 200 population. The residences are somewhat scattering, and located upon the spurs of several hills which converge here; and to get a view of the whole town one must needs get directly overhead. It was founded in this unique place by Mr. Blocksburgher, and all on account of being near that excellent spring. Mr. Block, as they all called him, for short, was a hale and hearty old man of about 75 summers, and occupied one of the leading stores of the place. For five years after the first establishment of the settlement, the only communication with the outside world was over a trail where every thing was packed in on the backs of mules. Another prime factor in the building of Blocksburgh, besides the spring, was its being the center of the wool industry. Over these mountains, and in the valleys, thousands

of sheep found succulent pasturage; and when wool was 40 cts. per lb., dollars were brought to the pockets of the sheep-herder; and the owner of a few thousand sheep in a few years realized a fortune. But of late, dull times had invaded these wilds, and the price of wool had subsided to less than 10 cts. per lb., and the industry was rapidly waning. Our visit to this wool country was just before the State election, and the politicians were much heated over the tariff problem; and tariff or no tariff on wool was their song, and the question is not settled even unto this day.

"There was a time," said Mr. Block, "when this store of mine was completely surrounded and nearly hidden from view with piles of sacked wool. It was brought in from the surrounding mountains, on mules, and the annual handling of wool amounted to the hundreds of thousands of dollars; and even now, when the price of wool is so depressed, the street presents a lively scene when a cavalcade of mules arrives with their immense burdens of wool," as will be seen by the photo. A large number of sheep-men came here in the earlier California days, and isolated themselves from civilization to a far greater extent than did ever a bee-keeper. These sheep-ranchers had much trouble with Indians, and Mr. B. said that, at one time, he could count up a hundred men who had been killed by the red man. Then there were saloon-rows that killed off a few more; "but," said he, "I believe there has not been a man killed here in a year."

The sheep-men finally sort o' compromised matters with the Indians by marrying their squaws, or, rather, taking them. Such were called squaw-men. Not a few were called men of the squaws, for they had taken a plurality; and the worst feature of this amalgamation of the races was that the squaw-men, many times without the least appearance of a troubled conscience, would leave their squaws and offspring to shift for themselves. The dusky wife had perhaps been a potent factor in making his fortune; but in his bettered worldly possessions he would move to town, build a new house, and marry a white woman.

We spent ten days in this town, and nearly every day some quaint character from the surrounding country would turn up. Here is an old man in from some branch of the Eel River, with a few boxes of fruit for sale. His apparel was ragged blue jeans; his toes protruded from an old pair of shoes; his hat was minus one half of its brim; his gray unkempt locks dangled over his shoulders; still this man could quote you scripture, Shakespeare, and Milton. He had been a man of books, and at one time had thoughts of the ministry. Even now it was said that he would make religious harangues to a crowd when opportunity offered. His hair he allowed to grow long, because in that he could imitate the lonely Nazarene;

"THE WOOL MARKET IN THE STREETS OF BLOCKSBURGH."

but I noticed he did not imitate that personage in his clothing; for through several rents in his blouse I could see the bare hide of the man, showing the total absence of a shirt.

In him was fulfilled the idea of the poet when he exclaimed:

Sad is a man without a wife;
Sad is a ship without a sail;
But the saddest thing to me in life
Is a shirt without—its proper length.

What could be more sad in this case than the absence of the entire shirt, the sail, and the wife?

The shoemaker's boy said his housekeeping was off the same piece with his general make-

the hot sun in their then exposed position melted a few of them to destruction, and the rest were moved into the dense shade of the redwoods, and here in various places the hives were mounted upon platforms attached to the trees, six feet from the ground. Hogs and cattle roamed the forest; and to keep them from their depredations, the hives were this elevated. The bees were not prospering in the shade, and they were to be moved out again. Of all trees to make a dense and cool shade, the redwood is the chief. Mr. Hope said that many bee-trees were found in these forests, and they were always well supplied with honey. His bees produced a good but dark honey. I pre-

CLIMAX ENG.
CLEVID, O.

MR. HOPE'S APIARY.

up; that his cat would lick out the frying pan, and then curl up in it for a nap; and his bed—here the boy's mother cuffed his ears, and he went away disconsolate.

Now, a bee-keeper would never degenerate into such a state of bachelorhood as that.

As a relief to the above picture, and in sharp contrast, I will show you the home of the only bee-keeper of Blocksburgh. Mr. Hope. Mrs. Hope is a hale and stout English woman, and Mr. Hope and Mrs. Hope's son are the blacksmiths of Blocksburgh.

The smith, a mighty man is he,
With strong and sinewy hands;
And the muscles of his brawny arms
Are strong as iron bands.

With these brawny arms Mr. Hope had cleared away the crown of the hill, and upon it planted a pleasant home. The vine and the fruit-tree were growing with a vigor such as can be induced only by a virgin soil. In the rear, and toward the east, the noble redwoods formed a fitting background, while the mountains shade off into the distance. Mr. Hope had at one time about 20 colonies of bees; but

dict that it will be a long time before bee-keeping as a paying industry will be practiced in these backwoods.

THE BEST FORM OF HIVE.

FOOTNOTES: WHY THE LANGSTROTH FORM OF HIVE IS BETTER THAN THE CUBICAL; A REPLY TO FRIEND BOARDMAN'S ARTICLE ON PAGE 251.

By J. H. Markley.

Mr. Editor:—I see, on pp. 251, 252, you allow friend Boardman to go on in his comparison of the square and long form of hives, showing the advantages of the former over the latter, without so much as using your footnote on him. He admits, in the very beginning of his comparison, that "bees adjust themselves to a wide range of circumstances, and even to serious inconveniences, in the hive they sometimes occupy, without seeming to materially affect the result." Now, "I am sure that this furnishes proof" that we should subject them to these little "inconveniences" by an "economical form of hive" that will give the best results in the production of either of the forms

of our finished product. I am well satisfied (by actual observation) that many bee-keepers stumble on to some form of hive "by accident rather than the careful consideration" of *practical* results, and whimsically conform to its inconveniences so long that the greatest amount of success with another and more "economical" form will not induce them to shake off the spell.

Of course, the square hive "furnishes more nearly the natural requirements" than the long shallow form; but doesn't the straw hive, as he says, or, for that matter, the hollow tree, furnish that quality to a still greater extent over the cubical? It isn't the "natural requirements" we're after, as much as subjecting the bees to these little inconveniences on their part, for the sake of the greatest financial results?

ADVANTAGES OF THE SQUARE HIVE.

In regard to the holding capacity of the eight-frame hive not being large enough, why not use a ten-frame L. hive, which affords the same "economical form in construction," and which affords no more "surface exposure," that I can see, if we consider both the ends as well as the sides of combs; and it seems to me that end exposure is more objectionable than side. If a square hive is desired in order to obtain a more desirable height for manipulation, why not elevate the long shallow hive to suit the fancies of the operator—a position, by the way, that many desire on account of the ravages of vermin.

SQUARE VS. LONG HIVES FOR WINTERING.

In the square hive, "at the beginning of cold weather the brood will all be hatched." Just so in the long hive. "This will leave the lower part of the combs empty, upon which the bees will be clustered." That's the way they do it in the long hive. "The stores," he says, "will be above the bees, in the most favorable position to be protected and preserved by the heat ascending from the cluster." I don't know about that. I will see you later. Again, "As winter advances, the consumption of stores enlarges the brood-nest of empty combs, and the cluster advances slowly upon the stores above them." Say! hold on! Isn't it a fact that, but for the short warm spells during winter, that permit the bees to carry stores from any direction in the brood-nest to the center of the cluster, they would starve, the shape of the hive notwithstanding? Again, isn't it a fact that brood-rearing invariably commences in the center of the cluster where the outside honey is being carried? Speaking about dormant clusters moving on to the stores—why! dormant clusters are dormant—they don't move. If cold weather compels them to stay dormant long enough, the bees will "go up" while the temperature goes down. He says, "Stores of honey exposed for any considerable length of time to the cold become candied,"

etc. Now, the past winter I had honey granulate all around some clusters, I believe, by the heat generated by the bees evaporating the watery portion of the stores.

As space forbids a more minute criticism of friend B.'s article, I shall be content if allowed to enumerate a few of the many advantages of the long shallow hive, from my point of view.

ADVANTAGES OF THE LONG HIVE.

It is more shallow, hence less liable to blow over. It takes narrower boards in construction, and consequently is less apt to season-crack. Combs are less liable to break down by high temperature. I have seen dozens of hives with American frames, where every comb in some cases would collapse at a high temperature, but never one with shallow combs. Combs being shallow, they are easily removed from the hive—you don't need one side of the hive knocked out. Combs being shallower than in square hives, the bees enter the supers more readily. We all know that bees will work above quicker if a one-tier super is used instead of a double-tier, and still a shallow hive with *two* tiers of sections is but very little taller than friend B.'s; consequently it stands to reason that better results may be expected from a long shallow hive than a square one which, in consequence, is taller.

Carbondale, Kan.

[It is true, I made no answer to the article on page 251. Inasmuch as I knew our friend Boardman had more to say on the same subject, I decided to reserve my footnote until that time. Well, if you will turn to page 296, April 15, you will find my answer. But I do not like, as a rule, to "footnote" an article so hard as to spoil its force; indeed, I would never do it unless I thought the teachings were liable to do harm, or were founded on error. Mr. Boardman produces good arguments for his side, and to a great extent I should prefer to let them stand, so far as I am concerned. But suppose I had "footnoted" it so hard as to knock his arguments into smithereens, then there would have been no occasion for your writing the above valuable communication. If the editor tried to make every article lean his way, and break down the force of every article leaning the other way, his journal would be narrow, biased, and teach nothing but one-sided truth.—Ed.]

LARGE HIVES.

THE LONG-IDEA HIVES.

By W. S. Hart.

Mr. Root:—I have just read Mr. J. A. Nash's article, on page 348, on "The Large or the Small Hive;" also the two that follow it, favoring the large hive, and I fully indorse the three in nearly every point on which they treat. As I have not followed this discussion of "Large vs. Small Hives" from the beginning, I will not attempt to enter it farther than to give my choice and a few facts and conclusions bearing on the matter, for fear of merely giv-

ing a repetition of what has already been published.

After many years of successful honey production I am fully convinced that, for the most profitable results, a large hive must be used, and this is especially true in the case of the production of extracted honey. Nor do I believe that this necessity is a local one to the extreme South, though possibly more marked here than further North.

In 1877 the writer was using a small hive of one cubic foot capacity, with (during the honey-flow) a half story top section over it. The outcome was a moderate yield of honey and a very large yield of swarms. As I then desired increase more than honey, the hive served my purpose exactly. Later, as my wish for a goodly number of colonies was being satisfied, my desire for a larger number of bees to the colony increased. I plainly saw that, in this direction, lay the accomplishment of my ultimate object, that of getting the greatest amount of honey with the least expense of money, time, and labor.

I made a lot of eight-frame L. hives, but found they did not give room enough for brood-rearing in the spring, so I left the top sections (the same size as the bottom sections, but supplied with but seven frames) on the year round, and put on extra ones during the honey-flow. This arrangement curtailed the swarming impulse to some extent, but there was a good deal of unnecessary work to be done, and the second-story combs had about as much brood and pollen in them as those of the body of the hive. I would occasionally find brood in every frame, except the outside ones, and, sometimes, some even in them in both stories. This left me no clean bright combs in the two-story hive for surplus honey, and no room for storing without a third story—a hand-to-mouth condition that I do not want in my apiary at any time. I concluded that there was little danger of getting hives too large, so I made ten frame hives for L. frame, and with top sections on the year round, and used them side by side with the eight-frame hives for some years. Through what seemed to me indisputable proofs of their superiority, I was led to increase the number of the ten frame hives while the eight-frame hives have gradually found their way to the attic of my honey-house, where now all but one are nicely tiered up awaiting a purchaser in some one who prefers a small hive.

The reason I did not adopt a twelve-frame hive is, that they are too heavy for one man to handle. When Mr. Olaf Olson came to this country he asked my opinion as to the best size of hive, and I told him that, except for the awkwardness in handling, I preferred the twelve-frame. He made a few of that size, to test my conclusions, and from them secured some astonishing yields. I saw one of these

hives, three stories high, at his apiary, full from top to bottom of brood and honey. He told me that it had been extracted from but a few days before, and that it had been refilled as quickly as the smaller hives beside it. By actual weight this colony brought in 24 lbs. of mangrove honey in one day. There was no shenanigan about this colony. It was the progeny of one queen only, and had no special care over and above the others about it. One only, I believe, of our most successful apiarists of this section uses the eight-frame hive, and he tiers them up high to get the necessary room. If bee-keeping were my specialty, and my ambition required that I make an astounding record of a great honey-yield with least labor, a "Long Idea" hive, taking 16 frames, and a division-board, with a regular ten-frame top section, supplied with 9 L. frames to put over it during the summer honey-flow, would fit my wants nearer than any thing else that I now think of. Other matters claiming my attention, however, and the proposed change being an expensive one, I manage to be reasonably content with last season's record of 554¼ lbs. from one colony, and an average, on 116 colonies, of 354 lbs. per colony from two-story ten-frame Langstroth hives with nine frames in the top section.

The freezes of last winter have so changed the conditions here that it will be two or three years before we can reasonably hope for another large yield of mangrove honey.

Hawks Park, Fla., May 25.

EIGHT FRAMES NOT ENOUGH FOR SOME QUEENS.

HOW EXTRA ROOM IS SUPPLIED AT DR. MILLER'S.

By Emma Wilson.

We have decided most emphatically that eight frames are not enough for some of our queens, as some of our strongest colonies have ten and eleven frames of brood. In the spring, as soon as a colony gets pretty strong, say with about five frames of brood, we put an extra story of brood combs under the colony. We have two objects in view in doing this. First, if the queen feels crowded and wants more room, she can enlarge the brood-nest at her pleasure. Second, the combs are nicely taken care of by the bees, and, if not needed, no harm is done.

Last year the weather was delightfully warm; and in some cases, where the colonies needed more room, we placed the extra story on top, as that was less work than putting it under, and in a few cases put a frame of brood in the upper story to induce the queen to go up sooner. Shortly afterward we had a cold snap; and the consequence was, the bees had a bigger contract on hand than they could care for. It makes a big difference whether the empty space

is above or below the brood-chamber. In every case where the empty story had been put under the cold snap had not seemed to affect them much, while those that had the empty story put on top had not increased in brood, and in some cases had less brood than when the extra story was given.

This year we profited by our former experience, and all extra stories were placed under the brood-nest, although up to May 12 it was the warmest spring on record. After that we had some extremely hard freezes, with about two weeks of cold weather.

I spoke of giving extra stories, but it is not the intention to leave them on during the honey-harvest. They will be taken away when we put on supers, with the exception of a few which may be left on for experiment. We have also put a few colonies in 11-frame hives for experiment.

We hoped that, by giving our strong colonies that extra story of combs under, it would do away with the swarming fever; but I am sorry to say I can not see that it makes much difference. Nearly always we find queen-cells in these colonies first, not because of the extra stories, but because they are the strongest colonies. Now, we know that the Dadants have little or no swarming because they use large hives and give the queen plenty of room. What's the trouble with our colonies? Are not 16 frames enough for the queen? That's more room than the Dadants give. Is it because they are in two stories? The queen seems to go readily from one story to another, and we find five and six frames of brood in each story, and queen-cells started. What's the trouble?

Why do our queens behave so differently from Mr. Hatch's? He finds difficulty in getting his queens to return to the lower story after going up, although the lower story is filled with bees and brood, while our queens go down of their own accord into a story of dry empty brood-combs.

As I said in last number, our feeding this spring has not been a very great success so far, as the bees have been so slow about taking it. In two or three cases the feed turned to vinegar on the hives. If that feed had been placed a distance from the hive, and those same bees had had a chance to get at it, I think they would have taken it eagerly, as they were promptly on hand in any case of outside leakage. I wonder what makes the difference. Do they think it's all right as long as it's in the feeder over the brood-nest, and theirs to be taken at their leisure, and they must hustle if they get their share when it's away from the hive? It looks like it, if we may judge from their actions.

They are doing better about taking it, now that fruit-bloom is gone, and dandelions nearly so.

Marengo, Ill.

TWO QUEENS WITH A SWARM.

Question.—Does a colony of bees ever have two queens? I hived a swarm of bees the other day that had two queens, I am pretty sure. My neighbor tells me it was two swarms, as he says there is never more than one queen in a colony.

Answer.—Probably both you and your neighbor may be right in this case, but you have got things a little mixed. I think such a thing was never known as a prime swarm of bees coming from a colony in a normal condition, having two queens with it. To be sure, we do sometimes have two laying queens in a hive at the same time, although such is a rare exception; but no colony was ever known to swarm at such a time, and both of these laying queens go with the swarm. With a prime swarm, or what is often erroneously called a first swarm, there always accompanies it a laying queen. All swarms having a young or virgin queen should be classed as after-swarms. When a prime swarm issues it generally leaves maturing queen-cells in the old hive, from which, when hatched, the young queens lead out all after-swarms. The only exception to this is that hinted at above, where, from some cause, the old queen dies near the swarming-season, when several queen-cells will be formed on the brood left, so that young queens may lead out what appears to be a prime swarm, the same as they do after-swarms. For convenience, all swarms except the one having the old or laying queen are called after-swarms by bee-keepers, so the readers may know what the term "after-swarms" means. Some days after the prime swarm has issued, the first young queen emerges from the cell; and if after-swarming is considered to be best, in the economy of the hive, the other young queens are kept in their cells by a little knot of bees clustering on them at all times, so the lid of the cell can not be removed to let the queen out, her majesty being fed all the time through an aperture in the royal cell. If further swarming is not considered "economy" by the bees, then all the other queen-cells are torn down and the young queens destroyed, so that the first hatched is the only queen in the hive. If the cells are protected as above, the first-hatched queen seems to get into a rage, and utters shrill notes at intervals, called the "piping of the queen," which is kept up for about two days, when the second swarm, or first of the after-swarms, issues. This piping of the queen is always heard, if listened for, before all after-swarms, or in any case of a plurality of queens in a hive intending to send out a swarm. The queens kept back in their cells by the bees are growing in age and strength, the same as is the one which is out, they telling of this by their trying to pipe the

same as the one does that has her liberty, which noise is termed "quahking;" and so it happens that, during the hurry and bustle of the second swarming, one or two of these queens hastily finishes biting the cover off the cell and gets out with the swarm, in which case two or more are found with the swarm, as in the case of our querist, although it is a rare thing to see more than two or three queens with a second swarm. If a third swarm is to issue, the bees now cluster about the remaining unhatched queen-cells as before, keeping all queens prisoners except one, which queen scolds or pipes away, as did the one before, the others in the cells showing their anger back again by a chorus of quahkings immediately after the first ceases piping, when, after the lapse of two days or such a matter, the third swarm issues. As there are fewer bees at this issue than there were before, and more mature queens held as prisoners, the queen-cells are quite generally vacated by the guard-bees; and queens, bees, and all rush out, and in such cases I have counted as many as from 12 to 20 queens with one such swarm, though from one to five is the usual number. In the above I have tried to give a short insight into the mysteries of the swarming of bees, many points of which do not seem to be fully understood, even by those who have kept bees for ten years.

WHICH WAY SHOULD HIVES FACE?

Question.—Should a hive face north or south? Would east or west be preferable to either?

Answer.—Nearly all bee-keepers agree that a hive should never face north of an east-and-west line, the majority favoring a southerly direction. The reason given for this is, that the morning sun entices the bees out to work earlier in the day, while a northern exposure keeps them in later, and in winter is almost sure to result in the loss of the colony in northern latitudes, from our rigorous north winds blowing in at the entrance, and the confinement of the bees, caused by the entrance being in the shade on mild, sunshiny days, when the bees in hives facing south fly freely. In southern latitudes it might not make much difference which way hives face; still, I have the impression that even in Florida and Texas the most of the hives are faced as above.

SHADE FOR HIVES.

Question.—Is it best to have a roof over the hives proper, or have them under trees for the purpose of shade?

Answer.—Some of our best bee-keepers use a shade-board made of lath or light lumber to shade the hive during the hot summer months; but if the locality is at all windy, a weight of some kind must be used to keep the wind from blowing them away. This weight is generally a 15 to 25 lb. stone, which adds very much to the labors of the bee-keeper, as it must be lifted off and on every time the hive is manipulated. Shade-trees (not very dense) are always good, not only for the bees, but they add much to the

comfort of the bee-keeper; but it often so happens that not every desirable spot for locating an apiary has such trees upon it. After having tried all kinds of shade I now prefer to paint the hives white and let them stand in the sun, where there is no danger of the cover leaking. White has a tendency to reflect the heat rather than absorb it; hence any thing painted white does not become nearly as hot as do the dark colors, so the bees in white hives remain comfortable at times when those in dark hives are driven out by the heat.

DEATH OF MRS. O. O. POPPLETON.

The following letter tells us the particulars of this sad event:

Friend Root:—I have just received very sad news from friend Poppleton. His dear wife Mattie died, after a short illness of less than a week. He writes me that they did not have any idea the sickness would be fatal until three hours before she passed away. She was taken down with a complication of diseases, but the final cause of death was heart failure.

Mrs. Poppleton was a native of Indiana, having been born in Maysville about 41 years ago. She will no doubt be remembered by a number of bee-keepers, having attended the national convention at Cincinnati in 1882, and Toronto in 1883, besides other State conventions. She was a well-posted and enthusiastic bee-keeper; and ever since her marriage to friend Poppleton she has been his first assistant in the practical care of the apiary.

Mrs. Poppleton has been a consistent and prominent church-member for thirty-one years, having joined the Methodist Church when ten years old. Cheerful, kind-hearted, and a lady in every sense of the word, to know her was to value her highly; and in her death, the community in which she lived sustains a heavy loss. While the few who were privileged to class themselves among her intimate friends will feel their loss deeply, I know how much friend Poppleton needs their sympathy in his great bereavement. H. W. MITCHELL.

Hawks Park, Fla., June 4.

[Our readers will recollect that Constance and myself spent several days at the home of friend Poppleton. Very soon after my arrival I was deeply impressed with the bright Christian faith and hope that continually shone forth from every look, word, and action of our departed sister. The Bible was her constant companion and friend; and when writing some of my notes for GLEANINGS, if I wanted a scripture text she gave it with remarkable readiness, showing herself almost a living commentary on the sacred pages. It was especially at that Sunday-school I have told you about that I was impressed with the thought that Mrs. P. was a spiritual guide and sheet-anchor in that little community. Our friend Harry Mitchell has got it right, where he says the little flock there has sustained a heavy loss. I often think of that little new Congregational church, and of the little flock that gathers there each Sabbath. I believe they have preaching service only every other week, and this throws an additional responsibility on the little Sunday-school that is kept up on the Sundays when there is no preaching. May the great Father above sustain and cheer up our afflicted brother in his great bereavement. The dear wife was to a most remarkable extent his companion and helpmeet—not only in joy and sorrow, but through all his daily tasks. She went with him on his pleasure-trips, helped to manage the boat, and seemed to be in reality a part of his very self. May God give him grace to feel that she is his friend and companion still, even though she has stepped on, for the time being, a little before him.—A. I. R.]

TRADE NOTES.

THE ASPINWALL HIVE.

By F. L. Thompson.

One logical inference from the large and small hive discussion is, that any hive which can not be contracted or expanded frame by frame up to the maximum, without fussing with division-boards or dummies, is imperfect.

Two sizes of the Aspinwall hive are made—one holding 1 to 11 standard frames, the other 1 to 11 deeper ($17\frac{5}{8} \times 11\frac{3}{4}$) frames, or a $1\frac{1}{4}$ to nearly 14 L. frame capacity. I prefer the latter, as it fulfills the condition of perfect elasticity, while preserving the standard length. I see by the *Review*, however, that Mr. Aspinwall is not a supporter of large capacity *per se*. The original reason for the expansiveness of the hive seems to have been to make room for the introduction, between eight brood-combs, of non-swarming wooden dummy combs, half an inch in thickness, with cells open at both ends. These are still on trial, but promise much.

The left side (on the right in the figure) is a cleated $\frac{3}{8}$ -inch board, which, besides forming

keeping, under "Shade for Bees," "A colony of bees is a living, heat-producing body, and can be kept cool in the same manner that we keep our bodies cool; viz., let its clothing (hive) be thin, with a free circulation of air." This unpainted $\frac{3}{8}$ -inch front doubtless also facilitates the insensible evaporation of moisture. The rear of the frames also forms a $\frac{3}{8}$ -inch wall, separated by a bee-space from the back, which is a $\frac{5}{16}$ -inch board, bolted on with iron cleats. The permanent side, and the bottom-board, are of $\frac{3}{8}$ -inch lumber. A further aid to coolness is afforded by a space left under the removable side, closed by a strip when not in use. This accomplishes the same result as wedging up the hive, in a much easier manner. It is also handy in hiving swarms.

The bottom-board is fixed. If other things were equal, I would choose a loose one. But I prefer this hive with a fixed bottom to the next best with a loose one, especially as the fixed bottom has some undeniable advantages of its own. This bottom is easily cleaned, the front and side being open. I doubt, however, whether the fixed bottom may be regarded as an essential characteristic of the Aspinwall hive, unless so desired by the powers that be.

Simple castings, fastened by a screw near each end of the top-bars, complete the circuit of a bee-space elevation of the top edge above the frames; secure correct longitudinal spacing, and, in connection with the closed ends, prevent the bees from contact with the frame-shoulders, which thus remain unpropolized. These shoulders rest on a beveled railing which forms part of the framework, making an ideal method of getting at the frames, without introducing the fingers among crawling bees or dauby propolis. This feature also removes the most serious objection to the use of wide top-bars, which are usually hard to get hold of. The frames being spaced $1\frac{1}{4}$ inches, the top-bars are $1\frac{1}{4}$ inches wide and $\frac{5}{8}$ inch deep, which dimensions are best to avoid burr-combs.

The frames are held firmly together by a blunt screw turning in the side piece of the framework. Two blocks, the three dimensions of which are respectively equal to the width of one, two, and three frames, make the ordinary adjustment by their different positions between the screw and the movable side.

Closed-end frames, accurately made and held together so as to present a smooth surface to the bees, are easy to handle, and have several advantages of their own, of which, perhaps, the most important is that, in wintering and breeding up in the spring, the heat of the cluster is confined to the comb-spaces which it occupies.

The Aspinwall frames have two advantages

THE ASPINWALL HIVE.

one wall of the hive, also performs the functions of a follower. Being perfectly free from the hive, it is as easily handled as a frame, and is suspended in the same way. This freedom is secured by making the essential and fixed part of the hive-body consist of a framework, mainly of oak, bolted together. The remainder of the hive, except the frames, is poplar.

The front is open. The closed-end frames take up the whole space. The advantage of this arrangement will be seen by the following quotation from Hutchinson's *Advanced Bee-*

of hanging frames which ordinary closed end frames do not—no bees can be crushed under or back of the frame-ends, and the lateral play is considerable, amounting to about $1\frac{3}{8}$ inches.

Every one has noticed, in brood-chambers which are not extracted from, that a hillock of honey on one comb sometimes collides with

fore and behind, and the hive-stand below, made provision for a nearly continuous envelope of packing on all six sides, between two and three inches in thickness. The results were satisfactory. In the spring, frames were as easily got at for inspection as in summer, without disturbing the packing.

I did not have an Aspinwall super last summer, but have just filled one with sections to see how it works. I find it can be filled as fast as or faster than a T super. The cut shows the principle. Two sides, the rods connecting them, and the separators, are all there is of the super. The separators are turned to a right angle at the bottom, and have insets corresponding to those in the sections. The distinctive feature, which makes possible this simplicity, is the four round sticks which are used when the super is being filled, and afterward withdrawn. These pass through holes in the ends of the side-boards, and keep the sections to their proper place lengthwise until screwed up by the thumb-screws on the rods, while giving ample play for inserting the fourth section in each row. When the sections are all in, they can be temporarily wedged at the ends with a strip of the proper thickness, to keep them square until fastened. A flat board is then laid on top, to which a

little pressure is applied, and the thumbscrews are tightened. On removing the board, sticks, and wedge, the result is a homogeneous and smooth block of sections, which is conducive to cleanliness, as I can testify from having used another super in which the same result is achieved in a different manner. The sections can be scraped in a body, before being removed from the super. This super admits of contraction or expansion just as much as the hive.

The flat or the Higginville cover may be used on this hive as on any other, and it will

another on the next one, if the frame is drawn directly out or replaced without stopping to move the other frames aside. A closed-end frame is replaced by sliding its edges down past the edges of the next one, so as to avoid catching bees between. The figure shows how this is done in the Aspinwall hive, without any collision. The offsets on the sides of the hive, against which the last frames impinge, slant a little from the perpendicular, so that, when the hive is leveled and the frames screwed up, each frame slants; consequently the septum of the comb is a little nearer one side at the top, and a little nearer the other side at the bottom (the top and bottom bars being placed to correspond). Hence when one frame commences to slide past another, the parts of the combs which are then opposite are farther apart than when down, and the normal distance between them is attained only when the frame is completely down.

In manipulating the frames of an Aspinwall hive last summer I was always able to hold each frame close up against the next one when sliding it down, though occupied by a strong swarm, which put plenty of honey in the tops.

For wintering and spring protection I have had experience with but one of their devices. I believe there are several. In this, external attachments on the front and rear, internal ones on the sides, a tray above projecting be-

take any style of super. But if the Aspinwall super is used, a deep cover is necessary; and, after all is said and done, nothing is more thoroughly satisfactory than the old reliable cap, covered with tin. Rain and snow can never beat under it; and when, as in this case, it is deep enough to accommodate two section-

supers, thereby keeping the sections warm in cool nights by adding an internal arrangement to suit the taste of the individual, and has plenty of play, and does not need a stone to weight it down, and is never propolized, it can hardly be called "impractical."

I have no interest in the sale of this hive, but have written the above to call the attention of bee-keepers to new and practical ideas.

Arvada, Colo.

[Some time ago an enthusiastic admirer of the Aspinwall hive (advertised in these columns for a number of issues back) wanted to know why we did not have that hive illustrated in our department of Trade Notes. I had intended previously to have this done, but somehow I had not got around to it until my attention was called to it. I wrote to the Aspinwall Manufacturing Co., asking them, if they saw fit, to send a description, accompanied by engravings, or request one of the users of their hives to do so. As will be seen by the above, they acted on the latter suggestion. There are some features about the hive I admire; and although not having tried the same I am of the opinion that it will work very nicely. Not every bee-keeper will be pleased with the same kind of hive; and I am very glad that we can give our readers a fair and impartial view of several good hives.

Perhaps it would be well to say that hives that are made up in part of the end-bars of the frames have never been very popular. Most bee-keepers seem to prefer some sort of box or shell in which to put the frames. However, two of the largest bee-keepers in the world (Elwood and Hetherington) use closed-end frames without the protecting case during the summer, each side being closed up by a panel, something as shown in the Aspinwall hive above. The Aspinwall system employs the plan used by Quinby and Hetherington; but instead of using standing closed-end frames it used closed-end hanging. — Ed.]

J. P., Mass.—You can put bees into a newly painted hive as soon as the paint is dry. Paint is not offensive to bees; in fact, about every two years we paint all our hives while the bees are in them.

H. F. S., Pa.—The Dovetailed hive—in fact, all hives of modern construction—have plain, square edges. There is no danger of supers and covers blowing off, because the bees will fasten them on with propolis. Neither will the rain beat in and rot the edges that come in contact, as would at first appear. Beveled edges between parts of hives and telescopic joints have been largely abandoned.

F. C., Mich.—Noticing our advice in the A B C, to have hives face toward the east, says the hives he has facing that way have not done nearly as well as those facing in other directions. The directions we gave in the A B C book are general, and apply to most localities. If your prevailing winds are from the east,

then, of course, it is not advisable to have your hives point that way.

With the exception of the small trees, basswood seems to be profusely loaded with buds that will soon burst into blossoms. If these blossoms shall, later on, burst forth with dead loads of honey, the hearts of bee-keepers will be glad, in view of the fact that clover promises but little.

ALTHOUGH there has been very little honey coming in, our bees have swarmed earlier than usual. They swarmed out, notwithstanding there is plenty of room for the queens, and for the bees to store honey. The only reason the apiarist and I can assign for this is the extremely hot weather that made the bees think other quarters might be more desirable.

In the *Am. Bee Journal* Mr. G. W. McGuire, of Dark Ridge, N. C., comes out vigorously in favor of large brood-chambers, he having used them from 600 square inches up to 2172. The colony in that hive filled it in 16 days, and gave a surplus of 63 one-pound sections. The next spring he bought four colonies in small hives, and they did nothing but swarm, while this big colony gave 110 lbs. of surplus. He claims that so much honey in the brood-chamber is of priceless value to the bees. June 2, 1893, one of these colonies gathered 22 lbs., from poplar. Mr. M. claims to have one of the best honey localities in the world—poplar and basswood. It seems likely that Western North Carolina will not much longer remain the *terra incognita* it has always been, as it is doubtless one of the richest and most healthful parts of the United States.

BRO. HUTCHINSON has reason to be proud of the two articles in the *Cosmopolitan*, especially over the very fine photos from which the engravings were made. The two articles are written for the general public, and I hope that some time they may be incorporated in book form for general distribution. One very pleasant thing about it is, that the treatment of the subject is fair and impartial. It does not boom any particular hive, but simply talks *standard* fixtures and *accepted* opinions, leaving all the latest ideas and theories out. Mr. Hutchinson deserves a vote of thanks from the bee-keeping world for the masterly way he has given the general public *correct* information. I think there will be less talk about manufactured honey because it has been shown that hundreds of tons of pure honey can be produced right from the hive—all of it gathered by the bee.

BEES ON STRAWBERRIES.

IN the *Amer. Bee Journal* is an article from Hon. Eugene Secor, relative to the value of the strawberry as a honey-plant. It seems that, in a previous number of that journal, Mr. E. T. Abbott had claimed that bees visit strawberry-plants, in considerable numbers; but in the present number Mr. Secor quotes from a letter written by Wm. Kimble, of DeWitt, Ia., a man who raises berries by the acre and honey by the ton. He says, "It is a fact that bees never work on strawberries. I wish they did." Among others who write in the same way as to the utter uselessness of strawberry-blossoms for honey are W. S. Fultz, Muscatine, Ia.; G. M. Doolittle, and Dr. C. C. Miller. But when we consider what they do produce, we can easily excuse them for not giving honey too.

DO WE WANT THE APIS DORSATA?

IN our previous issue appears a petition having in view the importation of the *Apis dorsata*, from India. The editor of the *American Bee Journal* does not seem to "tumble" to the idea, believing that, if the government has any money to expend in that way, it would be better if applied in developing the known good races we have. Another writer thinks such bees could not be domesticated in a cold climate, and that they would not take kindly to hives, and they would not breed with our common kinds. He fears, furthermore, that, even if successfully introduced, they might increase so as to utterly run out the smaller bees, just as the miserable English sparrow has encroached so much on our useful birds—giving us in his own person nothing pretty, good to eat, nor pleasant to listen to. If my own enthusiasm for the *Apis dorsata* is not up to the boiling-point it is because I do not think it would pay for the trouble, even though they might not prove to be a nuisance.

SHALL WE MERGE THE BEE-KEEPERS' UNION
AND THE NORTH AMERICAN INTO ONE
SOCIETY?

IN the last number of the *Review*, Bro. Hutchinson hits a big nail square on the head in regard to the necessity and desirability of bringing about better organization among bee-keepers in this country and Canada. The plan is, at least in the rough, to have all the smaller local organizations auxiliary to the State society, and then in turn have all the State societies auxiliary to the (or a) national organization—or better, perhaps, a continental union. In an able editorial on this subject the editor says:

For these reasons I think it would be better if the North American and the Bee-keepers' Union were merged into one society. As it now is, the members and officers of the Union never hold any meetings. All discussions are made either in the journals or by mail, and all voting is done by mail. To the plan of voting by mail, I see no objections; but I do think it would be an advantage if the officers and leading members, or as many as wish to attend, could meet

in convention once a year and discuss ways and means face to face. When there was a change made in its constitution three years ago, the subject was first discussed in the journals, then continued in a meeting of the North American where certain changes were recommended and finally adopted by the Union, a decision being arrived at by means of a vote made by mail.

And again:

There are many things, aside from those already done by the Union and North American, that might be done by such an organization with an efficient executive officer at its head and money in its treasury. The feature mentioned by Mr. Case is a case in point; viz., that of looking after and reporting swindlers. I don't know that the constitution of the present Union would need any change to allow of such work being done. Two or three times the *Review* has exposed some swindler; but this was not done until numerous complaints had been received, and considerable time had elapsed. To call a man a swindeler because one man *said* so would often lead to unjust accusations. When an apparently just complaint is made, the Union could make a thorough investigation—more thorough than one man could afford to make.

I have long thought it would be a good idea to merge the Union and the North American into one society; and I am glad that Brother Hutchinson has set the ball a rolling. Then the North American could offer substantial advantages for becoming members of the same. While it would have its annual meetings as before, the fraternal handshakes, etc., the members would be entitled to protection from unjust legislation, and perhaps from swindles of all kinds. I do not know that I am prepared to say just yet that such a merging of the two societies would be wise; but I think the matter should have the earnest and careful consideration of bee-keepers. It is a good time now to discuss it, preparatory to the meeting that is to be held in Toronto.

THE CLOVER-MIDGE; ITS WORK UPON THE RED
CLOVERS.

THE clover-midge seems to be making serious havoc in this locality, at least on red clover. As I go out on my trips in the fields for pleasure and health, I find that fields of red clover look as if they had been literally riddled with shot. The leaves are perforated with holes anywhere from a sixteenth to a quarter of an inch in size. In every field this clover seems to be similarly affected. On top of this is the drouth; and the consequence is, the usual rank-growing pea-vine clovers look poor and feeble compared to what they ought to appear at this time of year. But I have not yet so far noticed that the midge has attacked the white or alk-sike clovers. Why they appear to be proof against this pest I do not know. This surely is fortunate for bee-keepers, because the large bulk of clover honey comes from these white varieties. I believe it is generally admitted by writers on agricultural subjects that the white clover seems to be proof against the midge. I

should like to hear from our readers, especially Prof. Cook, who may be able to give us more definite information on the subject.

THE HIVE DISCUSSION.

ALTHOUGH the hive discussion that has been going on in our columns may be a little confusing, from the fact that one side very able defends the eight-frame side, and the other just as ably shows advantages in favor of 10, 12, or even 16 frames, I think light is surely coming if not already here. Perhaps this discussion may be tiresome to some; but it seems to me it ought not to be stopped yet, although we have prolonged it longer than at first anticipated. The proper solution of the question for each individual means dollars and dollars. I see no way but that each one must weigh the arguments advanced by both sides, and then consider his own *locality*. I will say this much, that the defenders of large hives have shown a stronger following than any of us had any idea of; and it is evident, too, that there is a tendency toward the large sizes in some places. As for ourselves—that is, we here at the Home of the Honey-bees—we shall have to see stronger proof yet to induce us to change to a larger hive, although we shall be experimenting, and shall hold ourselves open to intelligent conviction. I think that, in the majority of the localities, the eight-frame hive is still the best. We shall have something pertinent on the subject in our next issue by J. E. Hand.

FIVE-BANDERS; THE TIDE TURNED AGAINST THEM; PROMINENT QUEEN-BREEDERS ARE GIVING UP THE BREEDING OF THEM.

We have several letters from prominent queen-breeders all over the country, condemning the five-banded bees on the grounds that they are short-lived, not good at wintering, are bad stingers, excessive breeders, etc. I am sorry I am not at liberty to give you their names; but one or two of them will probably have something to say about what they think of them, over their own signatures, in an early issue of GLEANINGS. I noticed in the last *Progressive Bee keeper* an article by E. T. Flanagan, with the headline reading, "The Five-banders are no good as Honey-gatherers." Mr. F. says:

If the advocates of the so-called five-banded bees could have been with me when I overhauled my bees this spring and noted the condition they were in as compared with the leather-colored Italians and first cross hybrids, they would never advocate their dissemination or propagation again. With exactly the same conditions as to hives, locality, treatment, amount of stores, and condition throughout the season, all were as like as possible; but in every case this spring the dark Italians and hybrids were found in good, fair condition, with no loss, scarcely, whatever, while the five-banders were reduced to mere nuclei, or were entirely dead, leaving plenty of honey (sometimes as much as twenty-five pounds) in the hives. Friend Alley, in his denunciation of them, has been fully vindicated if others' experi-

ence tallies with mine, and I judge it does from the reports in the bee-journals that have come to hand.

At the end of the last season we introduced a good many five-banders into our yard. Of the four or five colonies that we lost in wintering, three of them were of the yellow sort. They were such bad stingers all through the summer that I made a firm resolve that, unless they improved very greatly, we would go back to the leather-colored Italians, and now we have hardly anything else in the yard. Last season it was hardly safe to work among the bees, without a veil. This year the situation is materially modified.

I am well aware that GLEANINGS has, in the past, said some unpleasant things of the five-banders. It was one of the first to raise its voice against them; and now I am not surprised that the whole bee-keeping world is going back on them. The whole trouble is, that queen-breeders, rushed with orders, did not take sufficient pains to breed for their bread-and-butter qualities as well as for color; and the consequence was, they sent out any thing that had more yellow than the average stock, irrespective of other qualities. Now, mind you, I do not say this is true of *every* queen-breeder who raised these bees; but the tendency on the part of most of them, I fear, was largely so. There are other queen-breeders I might mention, but I believe Mr. Doolittle is among those who are careful and conscientious in breeding these bees. In the *Progressive Bee-keeper* of June 1 he says:

I can not be accused of pushing this yellow craze to the front; but seeing it was coming, I went about breeding the yellow bee up to the standard of perfection as honey-gatherers, to the best of my ability, the same as I had been and am still breeding the three-banders. I have both three and five banded bees in my home apiary, and these and hybrids in my out-apiary, five miles away, but mostly hybrids at the out-apiary. Thus it will be seen that I was in a position to tell which did the best at honey-gathering. With a buckwheat yield, the hybrids would come in ahead; while with a basswood yield, the average would not be greatly in favor of either kind till last year, when, from some reason that is not sufficiently clear to me to decide upon, the five-banders were ahead by some fifteen pounds per colony on an average.

As I have intimated above, I have never claimed any superiority for the five-banded bees; and while I believe there is a great difference in bees, yet I believe that the result in honey is more largely due to management than it is to the race of bees used; and those bees which are the most pliable under the hand of the apiarist's manipulation are the *best* bees, no matter what their color or where they came from. If any queen can not be manipulated or coaxed to give the great bulk of her bees so they will be on the stage of action in the right time to take advantage of the honey-harvest, she should be replaced by something that can. That the five-banded bees, the three-banded-bees of Italian origin, and a good grade of hybrids, can be so manipulated, is why I hold on to them.

FLORIDA TRAVELS.

I told you I was somewhat disappointed to find Manatee only a little village. Well, in going out into the country, unless you happen to go into the neighborhood of some of the nice improved places like friend Bannehr's and others, you would be likely to decide the country was not very much of a place either. I can readily understand how people going to Florida for the first time, especially if they get a little homesick, might declare it was for the most part a barren wilderness of sand and stunted pines; and some of these folks who are not careful about what they say might declare it was a swindle all round. Some years ago a railroad was built from Manatee to Sarasota; but the rusted rails now lie unused, unless it is when they have a picnic or excursion, or something of that sort. There is not travel or business enough to run one train a day, and, if I am correct, not even one a week. We accordingly started out with horse and buggy, to visit friend Corwin, of Sarasota. After we had got out a few miles, however, it began to rain, and we changed our course a little so as to strike Oneco, where the Reasoner Brothers have located their nursery. I could not help thinking on the way that it was a wrong place for a nursery away out in those desert wilds. There were hardly any people, no railroads, not even a well-traveled highway. Imagine my surprise under the circumstances, to find myself abruptly ushered in to beautiful grounds with tropical plants and foliage everywhere. Of course, the recent frost had left its mark; but the Reasoner Brothers have learned by experience that it pays to have some protection, even in Florida. They have several greenhouses covered with cloth, and steam-pipes going about in almost every direction in case the cloth is not quite sufficient. They issue a catalog of over 60 pages; and some of their rare and valuable plants are worth large sums of money. It does not pay, they have found, to take risks with such things. Just before the December freeze they had been putting in a boiler, and had got up a good many of the pipes. When admonished of the danger, all hands were set at work; and by doing their best, toward midnight they got the apparatus in shape so they could get a fire under the boiler. Not an hour too soon was the steam sent coursing through the lengths of iron pipe. Only those who have been in similar trying circumstances can imagine what a breath of relief they drew when their apartments began to warm up in spite of the frosty wind outside. Several hours were passed very pleasantly and profitably to myself in looking over the wonderful plants and fruit-bearing trees and shrubs. For the first time I here got a taste of that queer little orange, kumquat (*Citrus Japonica*). They are oval in shape, and a little larger than a gooseberry. You can eat them peel and all, just as you would a gooseberry or cherry, and yet it is really a most beautiful and delicious little orange. Trees five feet high have given a yield of over 2000 fruits. Last season in Jacksonville they were so very much called for that commission men advertised to pay a large price for all that could be furnished. The lime-tree produces a little lemon, but it makes more delicious lemonade than any lemon ever produced, in my opinion. The giant bamboo was also seen here, but it had been killed by the frost. I shall have

more of this later on. The display of pines, palms, palmettoes, and sago-palms, etc., was just wonderful. We nowhere found such an assortment of cacti in Florida as we saw in Arizona and California, but some of them were very beautiful at the Reasoner brothers' nursery. Of course, we had much to talk about in the way of plants and machinery for irrigation as well as for preserving the requisite temperature for tropical shrubbery. Finally we took a look at the private residence of Reasoner Brothers, nestled down and almost concealed beneath the beautiful forms of trees and shrubbery. Notwithstanding the thousands of dollars' worth that was saved by their steam-pipes and cloth-covered greenhouses, their losses were quite heavy in valuable plants that could not well be protected. Florida, left to itself, presents many features that are rather discouraging; but under the influence of care and cultivation, no one seems to know as yet what Florida may not do. More of this anon.

Before leaving the establishment we looked into a room kept warm and damp, made especially for propagating from slips. For this purpose a certain amount of heat and moisture must be maintained with very little variation. But the skillful florist, with the right sort of bed, will take not only slips from a growing plant, but even a leaf, or *piece* of a leaf, and make it put out roots, and grow. Now, the Reasoners make use of this propagating-bed to bring to life plants that seem determined to die. Sometimes valuable plants are shipped in from long distances, that would be entirely useless without the reviving influences of this propagating-bed and a skilled man to manipulate it.

On the trip from St. Petersburg to Manatee, I noticed, when rounding the point near Palma Sola, a child dextrously managing a little canoe. The winds and waves were boisterous, and I, with the rest of the passengers, was looking anxiously toward the child in the skiff, as it seemed to be. We were a little surprised to see the skiff make straight for the steamer; and as it came nearer we saw it was a little girl in the boat; and, without deigning to notice the rough waves or the wind, she pulled her little craft right up beside the steamer, which slackened up and caught hold of her little boat long enough to give her the mail and take hers in return, for she proved to be, in fact,

ANOTHER GIRL POSTMISTRESS.

Before starting out again, however, we noticed she picked up a lot of fish, evidently just caught, and piled up a heaping pailful, which the mate of the steamer drew up, throwing her some silver coins in return. I was almost ready to protest against letting a child take such risks. But when she picked up her oars and showed herself more at home in a boat than I am on my wheel, I ceased being anxious. One of the passengers explained that she received quite a little salary for acting as postmistress, and fetching the mail from the daily steamer; and besides this she caught fish enough to supply the dining-room on our boat, both sources of income being sufficient to supply the needs of a widowed mother, and perhaps lay up something for a rainy day, or for her own education.

I believe I was snubbed only once during all my trip in Florida, and this once it was my own fault, or, perhaps, the result of my own carelessness. In fact, when I look back and think of it I feel a little surprised that I received such unvarying courtesy from man, woman, and child, even including railroad officials, everywhere and at every turn. But now for this one exception. On my return trip from Manatee I was glad to get another glimpse of the little girl who managed the boat with such

wonderful grace and skill. This time the waves were still higher, and it seemed as if she were really in danger as she threw up her bag of mail, caught the other in return, and pitched her fish into the pail that was let down to receive them. She evidently seemed to think she had better finish business as speedily as possible and get hold of her oars. When a bicyclist gets even one foot on his pedal he is master of the situation; and it is so with a boatman, only he wants to get his hands on the oars, to be able to defy the winds and waves that seem ready to work his destruction. Our little post-mistress made things fly right lively. She tossed the money into the bottom of the boat, catching with the other hand her hat, which the wind seemed determined to take away, then grasped an oar, settled herself back, and when the wild winds made sport with her brown curly hair, she by sheer strength and skill made her boat spring almost as if it were a thing of life, and had wings. I was thinking about making mention of her wonderful ability, here in these pages, and inquired of the passengers how old she was. No one could tell. I did not dare disturb her with questions until she had her boat well under control, and then I ventured:

"Please, sis, how old are you?"

As the boat prepared to shoot off across the foamy crest of the waves, she threw her head back, looked in the direction whence the inquiry came, and for one brief moment I caught a full glance of her dark lustrous eyes. She wore a jaunty sailors' cap; and for convenience (probably more than any other reason) the sleeves of her dress were such as to show her beautifully rounded arms that handled the oars with such strength and skill. Her complexion was, of course, brown, from the sun and wind, and there was not a bit of paint used to make her whiter than God had seen fit. Oh, yes! I have quite an eye for feminine beauty, even if I am toward sixty; but, dear friends, there never was a *painted* woman, old or young, who could, in my estimation, approach this girl, grown up, as it were, with the winds and waves. Before she opened her mouth to make a reply I saw that for once in the world I had blundered. I called her "sis," thinking she was perhaps twelve or may be a little more. Instead of a "sis" she was a miss of sixteen or perhaps eighteen. She looked me full in the face, with a saucy twinkle in her dark eyes, and with a little bit, perhaps, of natural pride (and, by the way, she has about as much to be proud of as any woman I know of), she replied—well, what do you think she did say, any way? Only this: "It isn't any of your *business*, sir, how old I am."

It was now my turn to feel hurt, and I colored up a little. But as she disappeared—or, perhaps I should say, as the distance between us widened—she vouchsafed to me a bewitching smile that allayed any slight wound I may have felt in the words she used. The smile said to me, "Oh! you need not feel hurt, my good friend; I feel pleasant and neighborly toward you all the same, even if I do not choose just now to tell you that I am not quite so much of a little girl, after all, as some people think."

The passengers bantered me some, good-naturedly, and one of them told me that he felt sure she had no thought of being uncourteous. She naturally attracted considerable attention, and was used to banter with the passengers, and had gradually fallen into a way of being perhaps a trifle saucy, or into a way of speaking that might appear so. May God be praised that women are at this stage and *age* of the world making themselves useful and independent in honest and praiseworthy callings, even

if their calling does sometimes bring them not only out into the open air, before the curious gaze of mankind; and may God help *mankind* at large to regard all such women as they would their own sisters and their own daughters; and may we rejoice that it is our privilege to stand before them to protect them, and to *defend* them, if need be, from every thing that is evil or unholy.

My next visit was at Thonototassa. Unless you have had a little practice in pronouncing this name you will have a good deal of difficulty in speaking it as the Florida people do. But our good friend Mrs. W. H. Stacey helped me to learn it by suggesting that I pronounce the first two syllables—*tho-no*—as one syllable; then pronounce the rest of the word as it is spelled, and then you have it—*Th'no-to-tas-sa*.

To introduce friend Stacey and his wife I shall have to tell you that, when O. O. Poppleton first spent a winter in Florida, he made his stopping place with these good people. Now, friend P. could not be anywhere very long without talking bees; and he not only *talked* bees, but he *made* a bee-hive, then a honey-extractor, and finally a foot-power buzz saw, without even a carpenter shop or tinshop to aid him; and the very extractor and buzz-saw were shown to me.

The Staceys are great poultry-keepers. Before I had hardly set foot in the dooryard I was charmed by beautiful flocks of White Leghorns. Each flock has its appropriate yard. Before I left I was permitted to assist in gathering the eggs. I have had all my life visions of a model poultry-establishment, with every thing so neat and tidy that it would be an unmixed pleasure to tend the "biddies" and gather the eggs. And here I found my dream almost realized. Mrs. Stacey suggested that, before I said too much about *their* poultry-establishment, I should pay a visit to their neighbor, Rev. J. H. Waddell. When we arrived, the pastor himself was absent; but his good wife very soon enlisted not only my whole attention but my enthusiasm by their beautiful home and their poultry-appliances. Why, the *whole establishment* looked as if it had been swept and dusted that very morning. The nests and the roosts, and every thing pertaining to Mrs. W.'s White Leghorns, was so unique and tidy that I turned to her and inquired whether she had really taught her fowls to wipe their feet on the doormat before they got into the nests. Now, there is *not* a very large amount of money laid out around the Waddell establishment. When I made some inquiries as to how many men they employed, our hostess replied she believed the pastor himself was the only *hired man* they had about the premises at that time. Pretty soon we found him coming along with a cartload of old brush and rubbish that he had been gathering up. Do you know, dear readers, that some people have a knack of keeping things neat and tidy, without paying out any money of any account? Others will keep a lot of help, and even then seem often worried with many cares and anxieties. I am afraid I belong to the latter class.

Now, ever since that pleasant visit I have been afraid that, in writing up this pastor's home away back in the Florida wilderness, I should make too long a story of it; so I am going to stop right here by simply saying that it was the pleasantest home I ever saw, either in California, Arizona, down south, up north, and I will not except even any thing I saw away down east in *Boston*. I have never seen any thing *anywhere* that so satisfied and refreshed my longings for a model home as this one of which I have been telling. Perhaps one secret of it is, the clean white sand that nature

THE GRAPE-FRUIT TREE THAT BORE \$30 WORTH OF FRUIT IN A SINGLE SEASON.

has spread so lavishly around this little home. But beautiful shrubs, plants, and grassy lawns were to be seen almost everywhere. And then a little gem of a drive went down through the wild tangled woods, and led along by a tiny lake, where the wavelets of pure crystal water rippled up against the soft clean sandy beach.

Two or three times I have been inclined to say that, so far as producing great crops is concerned, Florida is away behind the North; and I have heard others say that, without vast quantities of manure or expensive fertilizer, you can not raise a thing. Now, wait a bit. Friend Stacey pointed to a large grape-fruit tree standing at one corner of the porch, and incidentally remarked that he received \$90 for one single crop from that tree. I sprang to my feet in surprise. Said I:

"Now, friend Stacey, I have been greatly puzzled about this matter of fertilizing orange-trees, grape-fruit, limes, etc. What fertilizer, and how much, did you put around this tree?"

"Didn't put a bit of fertilizer of any kind around it, neither that year nor any other year."

"But, my dear friend, you certainly did give it some extra cultivation of some kind."

"Didn't give it any sort of cultivation, neither that year nor any other year. It just stood there and 'grew itself.'"

I walked around the tree, looked it over, asked how old it was, etc. Now, friends, when you hear people talk about Florida soil, and that there won't any thing grow down there, and that you can't get any money for your crop, just remember what I have told you, and take a look at the preceding picture.

Please remember, also, there were not any freights nor commissions to be taken out of the \$90. Our friend got the \$90 in cash for the fruit, right in his own dooryard. There is a part of this conversation that I once decided I would not tell anybody; but since several have complained about my extravagant stories in regard to Florida, I think I will tell it after all. Friend Stacey said that a neighbor of his got \$150 for the crop of fruit from *one single tree*. You get a few glimpses of the house where our good friends live. Now, right near by friend Stacey's is a cypress swamp, and the most beautiful cypress-trees are now being cut and taken to a sawmill near by. This straight fine cypress lumber is the kind used for greenhouse timbers, you know—rafters, etc. Well, friend S. actually "whittled out" his dwellinghouse from this cypress timber. He split out the boards and the shingles, and built a pretty home before sawmills were ever brought into that region. He is also quite a gardener. He is testing lathyrus and many of the other new plants. Almost everywhere in Florida they say they can not raise peas; but friend Stacey tells me he had a fine crop of Alaska peas, and they were picked before Christmas. The principal fertilizers used in his vicinity are cottonseed meal and sulphate of potash. This was all that was needed to get crops of almost every thing in that locality. Of course, they are beekeepers, but the locality has not ever given any very great crops of honey.

A Northerner is often greatly puzzled, and sometimes smiles right out loud, at the queer names and expressions used in Florida. For instance, a piece of light-wood means a blackened knot of pitch pine, almost as heavy as cast iron. A beautiful plump-looking bird is called a "poor Joe;" and the live-oaks that flourish in Florida are about the same as those I have several times described in California. Now you can understand the following which Florida folks sometimes repeat, to the perplexity of their northern visitors: "You take a chunk of heavy light-wood and throw it at a

fat poor Joe sitting on the limb of a dead live-oak." This is almost as bad as the expression, "Blackberries are always green when they are red."

Friend Stacey and his wife have some wonderful collections of minerals. In the vicinity of Tampa, along the shores of Tampa Bay, they find queer minerals called geodes, and chalcedony. The geode is a peculiar flinty quartz-like stone that is hollow inside, and filled with water. The crystallization, both on the outside and inside, reminds one of beautiful frostwork. How did the hollow come inside of the flinty stone? and, finally, how did this hollow come to be partially filled with water? The quartz is so transparent that, by holding it up to the light, you can see the water and the bubble of air that partly fills the cavity.

Thou shalt not covet.—Ex. 20 : 17.

On page 416, May 15, I spoke of a shell mound near friend King's. As we approached the excavation made by the railroad company in digging out the shells, friend K. was explaining to me that the excavating and throwing the shells on to the cars was generally all done by colored men. As we neared the scene of operations we noticed the men were not at work. Friend King asked a colored man the reason, and he replied that "yesterday was pay-day." After he was out of hearing I inquired why they could not work, even if yesterday was pay-day. The answer was:

"Why, after these people get their pay they will not work any more until they get rid of their money. In a few minutes we shall probably see the sad way in which they manage to get relieved of their funds before they can go to work again."

Right there was being enacted the sad scene right before our eyes: A sort of table or work-bench was placed in the shade of a tree. The men were all gathered around it; and so intent were they on their gambling that they hardly noticed that strangers were looking on at all. There was one rude hut or building in the camp, and a forlorn-looking woman was there to cook and prepare their meals.

"But how long does this gambling last, friend King? I suppose the dull ones, of course, in the game, or perhaps the most conscientious of the lot, will lose their money first, and drop out. In this way the circle draws down narrower and narrower until there are finally only two contestants, and in the end *one man*, the worst *villain* in the lot, probably, pockets all the money the rest have earned during the days and weeks that are past."

My companion turned around and looked at me, perhaps in a little surprise that I should know how these people managed when I was so little acquainted with them. I went on:

"But doesn't the final ending-up of the game result in quarrels and fights?"

"That is just the way it does end, Mr. Root; and the one who gets the money from all the rest has to run off, a good many times, to escape their anger. Of course, there is more or less cheating and sharp practicing, as there always is in this work, and bloodshed is not unusual at the winding-up."

Now, dear reader, this kind of work goes on and on in this land of ours so full of Sunday-

schools and churches. I could not discover that any minister, missionary, or pastor, either black or white, was making any protest against it. The railroad company probably did not interfere so long as the darkies kept the cars loaded as fast as they were wanted. If they spent so much time in gambling they could not do this, then I suppose more men or different men were put on. These colored laborers were mostly without families. They were a sort of adventurous, irresponsible set. Some of them were accustomed to change their locality as soon as they got into some trouble; and the vast extent of wilderness and swamps all about them made it an easy matter to evade the law.

Not long before, one of this same class of fellows shot a white man in a quarrel. He ran for the woods, but nobody put after him; and the locality was so far from towns or cities that it was almost out of the question to think of sending an officer of the law after him. Now, I do not mean to say that nothing is being done in Florida for the colored people. Again and again I was obliged to admire, reverence, and respect the efforts that are being made for the education and Christianizing of the race. Several times I walked through a part of different towns and cities allotted to the colored people. I saw the mothers and children. I saw the colored pastors making their calls, taking down the names of the people, number of children, ages, etc., and asking what church they attended. I believe these colored pastors are, for the most part, good men; and while I felt sad to see these men spending their money in gambling, I could not but reflect that they were by no means the only transgressors in breaking that last and important commandment. Let us look at it. These men worked side by side day after day, through the hot sun, and most of them did good honest day's work. One would suppose they might have a kindly feeling, one toward another; and that each one might feel happy, when payday came, in seeing his comrade get the reward of his toil. What sort of disposition or heart must a man have when he would voluntarily appropriate the wages of a fellow-workman? If he took it while this brother was asleep, it would be robbery. I do not know just what the laws of our land are in regard to gambling; but I do know that laws have been framed, time and again, in the endeavor to put it down. We respect in theory if not in practice the command, "Thou shalt not covet thy neighbor's house," etc. Is it not a fact that almost all the wrong-doing and wickedness in this world come about because men covet that which does not belong to them? Why, how can any man, woman, or child deliberately plan to appropriate that for which a neighbor or companion has worked hard? Why should we not have as much interest in seeing that our neighbor has his just rights as that we have our own rights and just dues? Well, it is because we are imperfect and sinful. It is because of the inborn depravity of humanity. I say *we*, because I am every day and almost every hour conscious that this sin of covetousness lurks in my own heart as well as in the hearts of others. I have worked and prayed industriously for years and years, and yet I am selfish still. God have mercy on *me* a sinner! In one sense, however, I am not covetous. I despise and abhor the man who would take from his neighbor without just and fair equivalent. I loathe and abhor the sight of a pack of cards, just because they have been the recognized tools of this kind of genteel highway robbery for ages and ages past. A certain class of people seem to be continually striving to make card-playing respectable. They bring it into

their homes, and they engage in games of cards with their own children. Sometimes they succeed, *apparently*, in proving that this terrible work is harmless and innocent. A man well to do once put a billiard-table in his barn, and told his boys that, when they wished to play billiards, to play at home. "Don't go off to doggeries; don't go in company with the evil and vicious. Play at home." Somebody, in telling of the above, claimed that the father had succeeded. His boys played billiards in the barn, and grew up to be straight, square men.

"Hold on, my friend," remarked a bystander. "May be what you have just said is all true—at least, we will let it pass for truth just now. But I happen to know a neighbor's boy—a child of Christian parents—one who started in church and Sunday-school, and who, I verily believe, might have been a good man this day had it not been for that billiard-table in the neighbor's barn. The boy started *there*. He started there because it was made respectable. He got his taste for gambling *then* and *there*; but now he is nearing a gambler's and a drunkard's grave. That billiard-table in the neighbor's barn spoiled him for every thing good and useful."

We pity, censure, and despise the poor colored laborers who have lost their money in gambling year after year as fast as they can earn it. But, dear friends, is it not true that they are only a little more bold and reckless in their manner of transgressing and breaking this tenth commandment?

The daily papers of this whole land of ours are just now teeming with accounts of hundreds and thousands that have been stolen on the sly. A good deal of the time the money is taken from the government by some sharp management. Men get into office by bribery, and then they seem to think it is expected as a matter of course they will get their money back that they have expended, by some hook or crook. Officers of the law agree to let offenders go on in their transgression providing they *pay* them enough, etc. Are there no people left who do not want and can not be hired to touch that which justly belongs to some fellow-man? or that which justly belongs to the United States and our public institutions? Oh, yes! there are a good many people; but there are so many things to be seen to and looked after, with all the machinery and multiplication of modern industries, that good people have not time to look after every thing; and a good many of them have such a dislike for going down into the filth and wickedness to straighten things up that they leave it for somebody else to do. Here and there a wicked man is converted to Christ Jesus, and loves his Savior more than he loves any thing Satan has to offer. Even should the prince of darkness say, "Here, I will give you the *whole world* if you will fall down and worship me," we have instances of men who stand firm and steadfast at their lives, who never yield to Satan one inch;* but as

* Yes, I have met quite a good many men who value a clear conscience, as they go to bed at night, more than they value the money they may have received during the day. Why, a good many times people have come to me, saying, "Mr. Root, you paid me a little more than you ought, in that deal yesterday."

When I look up and laugh at them (I always feel like laughing in real good nature and joy when that unselfish feature of humanity comes out), and tell them I guess it is all right as it is, sometimes they will say, "Well, did you get rid of the stuff so as to come out whole?"

If I hesitate a little, down goes the hand of my neighbor into his pocket, and out comes a handful of silver.

time goes on it seems almost as if the dens of wickedness furnish *bad* men faster than all the churches and missionaries can furnish *good* men; and the saints are, to use a slang phrase, "snowed under." But they need not be. God's promises are to the effect that one who is consistent and faithful shall be more than a match for a hundred of the vicious and covetous.

But you will notice that this text of ours does not end up by saying, "Thou shalt not covet thy neighbor's money." It does not say any thing about money. It commences by saying you shall not want his house. It is a sin to be envious because your neighbor has a better house than you have. And then after mentioning the house it speaks next of the neighbor's wife. I can remember that it used to seem singular and strange that this enumeration should come in just this order. But Satan knows his business. He knows that many a man might stand firm and immovable so long as money or property only was concerned. The man who wrongs his neighbor out of money, or even out of his house and home, can, if he repents, give back the money with interest. He can give back his house and home, or a better one; but one who steals from his neighbor the wife and mother, can never restore that home as it was before. He has not only taken the path that leads down to hell, as the scriptures tell us, but he has led another human being down to hell along with him. And who shall tell of the wreck and ruin that follow on for generation after generation?

It is a terrible thing to want any thing that belongs to your neighbor—of course, I mean in the sense of wanting it without giving for it any proper equivalent; and it is the sin and shame of our nation to-day that our children are permitted to grow up without more careful training in regard to this one matter of respecting the rights of others. If everybody loved and enjoyed the privilege of sacredly and solemnly living up to this tenth commandment this world of ours would be a heaven here below. But, on the other hand, if mankind continue to grow up, not only wanting but greedily appropriating all they can get hold of, it will make this world of ours—nay, to come nearer home, this United States of America—a veritable hell on earth. If we continue to look up to men, to respect them, and to treat them with courtesy—men who would, without doubt, do just as the poor darkies are doing down in that shell mound, pocketing the earnings of the *whole crowd* if they can get it—then our nation is surely doomed.

A few days ago, when it was first announced that one of the great political parties of Ohio had nominated a man as candidate for govern-

or, the first comments I heard were disapproval; and the principal reasons for the disapproval were, that the politicians had nominated a *millionaire* for the office. It seemed as if the people of Ohio—at least a considerable part of them—took it for granted we did not want a millionaire. I do not know but they thought a man ought to be *ashamed* of being a millionaire. Why? Well, many good people have got into a way of thinking that a man has no business in being a millionaire—at least, a certain class are taking it for granted that he became a millionaire a good deal in the same way the boss gambler in that crowd of darkies succeeds in taking the entire earnings of all the rest of the crowd; and I do not know but they think (like this same boss darkey) after he has got it all, to be consistent he should run away and hide himself, or get among a new crowd that does not know any thing about his past record. I hope you know, dear friends, I do not wish to find fault with honest industry; neither do I wish to complain of those who seem to have ability to manage great numbers of men and hundreds and thousands of dollars, and also to manage large capital. But I am *hungering and thirsting and praying* that our nation of people, before they go a step further, may stop and consider this last commandment; that they may, on bended knee, ask God to take away all disposition or longing for their neighbor's house, or his wife, his maid-servant, his ox, his ass, or any thing that *belongs* to the neighbor.

A VISIT TO MATTHEW CRAWFORD'S.

During one of those exceedingly hot days that ushered in this month (in fact, it was on the very first day of the month) I took a notion to pay a visit to Matthew Crawford, the strawberry-grower. I knew it was a very hot day for a wheel-ride. Hot days have never very seriously interfered with my enjoyment on the wheel so far, and I thought I would take the chances. During the fore part of the route I enjoyed it as usual; but I stopped and sat down and rested by the numerous soft-water springs along the way, and sometimes stretched myself out full length on the green grass in the shade of the beautiful trees. But before the 20 miles were up I had become pretty tired. On the very summit of one of the great hills near Northampton, Summit Co., I sat down in a pretty dooryard to rest. Looking up I was surprised to see red (the red kind, you know) cherries, black cherries, plums, peaches, and almost all kinds of fruit, apparently unharmed by frost. This was clearly the result of the elevation. The cold air could run down on all sides into the valleys, away down below, and this gave that fruit-orchard on the hill almost perfect protection from the ravages of the frost. Here is a hint to owners of hilltops. And what is more beautiful than to see the summit of these great mounds made by nature covered with fruit-trees, and loaded with fruit, when the valleys and plains are destitute on account of the frost?

The day before I took my trip, Ernest took hold of the chain of my wheel and said, "Father, look here; you had better take that wheel right in to Henry now, and have him take up the slack in that chain. If you neglect it, the chain will be thrown off in going down

"Look here, Mr. Root, we know you are generous and liberal; but we don't want to take advantage of your good nature. Let me pay you back enough so you will come out whole in the transaction, any way."

How much good it does me to meet a man like that! We say to ourselves, "Well, there is one man at least that we can remember never needs watching." Pretty soon we find another, then another; and by and by we discover there is quite a little band of honest, unselfish neighbors around us—people who will not overreach and take more than their share, no matter how good a chance may fall in their way. We can leave our tools and produce out in the fields in such a neighborhood. We need not waste our time in fussing with padlocks on the tool-house, poultry-house, and granary, for such a spirit in the hearts of mankind is more secure and lasting than all the padlocks and iron safes that were ever devised by the art of man. While I write, it seems to me that somebody, years ago, said what I am trying to say, better than I can ever say it myself. "Behold, how good and how pleasant it is for brethren to dwell together in unity!"—PSALM 133:1.

a hill, and you may find yourself in a worse predicament than you have ever yet been in all your wheeling adventures."

Now, I intended to do exactly as Ernest suggested, but it was overlooked. In going down a hill near Ghent—sure enough, off went the chain. At first I felt a good deal distressed to find the cranks of my wheel turn loose, and give me no control whatever over its motions or speed. The chain, however, seemed to keep out of the machinery until I almost touched the bottom, then it caught; but as it was soft sand, the rear wheel slid like a sled-runner until the machine slacked up so I could get off. I felt like calling myself a good many names for my stupidity and neglect. I hunted a shady place, then began feeling in my pockets for my wrench. The pump and oil-can were all right, but "nary a wrench." I rarely carry my tool-bag, because I try to dispense with every ounce in weight, especially during a very hot day. Then I remembered laying the wrench down on the window-sill at the factory, 15 miles away. I put the chain back in its place, however, and concluded it would probably go all right if I walked down steep hills. I went down several hills of moderate decline, and every thing seemed to be safe and sound until I ventured on one that I felt on the start was a little bit risky. When half way down, off went the chain again. With no back pedaling, of course the wheel began to go faster and faster. I dodged innumerable rocks, set my teeth, and held the handle-bars with a grip of iron. All this time the chain was clattering; but finally it caught in the sprocket-wheel, and there was a zip, and a rattling of steel, then I heard the chain fall to the ground. It was broken. It made me think of a fractious colt that had succeeded in kicking loose from sulky, whiffletree, and even the traces. I felt like yelling to somebody to "stop us." But there was no one in sight. My 18-lb. Rambler seemed to be a "rambler" indeed; and even when it got on level ground it would not stop. It went up another hill and down on the other side. I began to think of Darius Green and his flying-machine. Finally the wheel gradually slacked up, and I got off. I had been thinking that morning that I needed a good sweat; and I got it that time. It was not the sweat of physical exertion, however, as much as it was *mental anxiety*; and then I found I should have to walk the rest of the way during that terribly hot sultry noontime. I could not ride up hill without a chain; and I could not ride down hill—at least if it was very *much* down—because I was afraid. But I did sail along nicely down all gentle inclines, and even on a rather level road; and with a brisk wind behind me I made pretty fair speed. At one point I came down a long gradual hill. At the bottom was a bridge, but the way was blocked by a peddler's wagon and a farmer. As I could not slow up I yelled at them all the way down hill to "clear the track." They evidently, however, could not see any reason why I should not slack up. But when I got near to them I explained to them that my wheel was broken, and that I had no control over it. Doubtless it seemed to them a little strange that I should be coming up hill at such speed as that without doing any pedaling. They moved, however, just in time to let me squeeze between the two vehicles by the pretty sharp guiding of my steed.

Beyond the hill I found a blacksmith shop, and we two—the blacksmith and I—managed to mend the Rambler chain by taking out one link. He was a little slow on deciding just what price he ought to charge. Finally he said he guessed the use of his tools and his time might be worth a *dime*. I gave him a quarter,

and thanked him besides, and went away with the pleasant reflection that there were at least a *few* people in this world who do not want all they can get in every little deal. Yes, I was cheered by another pleasant reflection too: An 18-lb. Rambler wheel, without any chain or crank, would help me quite a little on my journey. But after you have ridden a mile or two without them, then you can realize as never before what a *superb* luxury it is to make the little light machine fly up hill and down, either slow or fast as you choose.

Friend Crawford was fixing a posy-bed in the shade of a tree, for Mrs. C. He is just about my age, and he said he had lately been deciding that he wanted to take life a little easier than he had been doing during the years past. I told him that was my sentiment exactly. Then we went out where three bright muscular young men were taking care of the strawberries. Two of them were his sons. My eyes soon caught a glimpse of the new Zephaniah Breed weeder. With this machine one of the boys had actually gone over two acres of strawberries newly set, firmed up the earth in the most beautiful manner, and had not, so far as I could see, torn up a single plant. Why, if a couple of men with cultivators and hoes—yes, and rakes too—had worked two or three days on that two acres of strawberries they could not have fixed them any better than young Crawford did in perhaps two hours. And then the boys had got hold of some new-fashioned hoes which I greatly admired. You can make one by taking a common hoe and cutting off a portion of the steel in a line from one of the corners back toward the shank. It leaves an acute angle of steel at the corner that will go in between the plants, and mellow up the soil, or yank out a little weed. The hoe is just as good for all ordinary purposes as ever, has a sharp corner like a trowel, to get in where a common hoe could not. The frost had spoiled the greater part of their crop of berries; but they are going ahead with new plantations all the same.

§A RUNNERLESS STRAWBERRY

attracted my attention. The plant just keeps growing in great clumps or crowns; and if you make the ground rich enough, and have the plants far enough apart, you can, no doubt, get a quart or two from each plant. To get new settings you dig up the old plant and divide it up. I saw a row of nine young ones just made by splitting up one old plant. Another thing, you can put your strawberries of this variety in rows so as to cultivate both ways. I think this variety has never yet been offered for sale.

Friend Crawford finds it quite convenient to combine onions and strawberries. I don't mean that he mixes them up on the table, but just in growing them out in the fields; and, strange to tell, he has sort o' settled down on White Multipliers and White Top onions, just exactly as I have, and here he is only about 20 miles away, and we were sold out and seeking everywhere, while he was selling his crop for less than half what it was worth because he did not know where to dispose of it. Don't you see, friends, that it pays to be neighborly? Go around and see what others are doing in your line of business, and talk matters over.

THE ONION-MIDGE OF NORTHERN OHIO, OR NORTHERN THRIP OF THE WEST.

□ Mr. A. I. Root:—I wish to say that your talks on gardening, etc., are very interesting to me. It was through your note on the onion-midge that I learned what ailed my crop last year. My onions began to die during the drouth early in the season, that I thought were all right. I

could not tell what was the matter with my late planting, for the weather seemed favorable. I looked, and found the onions covered with the midge. I did not make over a third of a crop. In August we planted two patches of winter onions—No. 1 where the spring crop was grown; No. 2, 200 yards from where onions had been grown for several years. Patch No. 1 died nearly to the ground before winter, after they were knee high. Patch No. 2 was injured about half as much as No. 1. I sowed 8 oz. of Pearl seed the last of August; another 8 oz. Sept. 15th, in adjoining beds, 175 yards away from where onions had ever grown. The first lot of plants were killed nearly to the ground before winter, and the others were practically uninjured. A part of each lot were transplanted in December. Three-fourths of the first lot, both transplanted and in the bed, were killed by the winter. The second lot was uninjured. This spring the first lot was the first to be injured by the midge, except some of lot two that were planted beside the winter onions above mentioned, and began to show the effects of their work as early as any. These pests are in the ground in old onion-patches, also in the onions, sets, and buttons. But in the case of the seed-beds, where did they come from?

I sprayed a few onions with kerosene emulsion. That seemed to do some good; but thousands of insects came from the adjoining rows and covered them again. I will try acid on some of my later onions. Our druggist charges 45 cts. per lb. for carbolic acid. I fear that is too expensive to be used extensively. Then I fear the applications will have to be repeated frequently to kill those that come from the ground; or are they all on the plants while they are growing? I wish our experimenters would learn of some cheap effective way to get rid of this pest. It is my opinion that treatment, to be successful, must be preventive. I would suggest working the ground during freezing weather, or planting winter onions about the patch in August, then pulling and burning late in the fall, when they are covered with the insects. If water will destroy the midge, why would it not be a good plan to flood both patch and seed-bed, where possible, just before transplanting? The onion is my best-paying crop, but the midge will destroy three-fourths of it this year. I shall have to abandon the crop entirely if I can not destroy the little fellows.

Malvern, Ark., May 16. P. C. SHOCKEY.

The above was at once forwarded to our Ohio Experiment Station, and below is their reply:

Friend Root:—Our Prof. Webster, who has done considerable work with the insect referred to, refers me to a bulletin recently published by the Iowa Experiment Station, in which Prof. Osborne gives a description of the insect, under the name of the "Western Onion Thrip." It is one of those insects which do not have a particular liking for any special plant, but has been found on squash, turnip, catnip, sweet clover, cucumber, and many other plants. The eggs are laid beneath the surface of the leaf; and as soon as they hatch they begin to feed on the plant-tissue. They evidently grow quite rapidly, and there are, in all probability, a number of generations each year. They live through the winter in both the larval and adult form, and begin to multiply as soon as vegetation is ready for them.

The insect has never yet, except in exceptional cases, been so troublesome but that successful remedies have been found to meet it; but Prof. Osborne thinks that kerosene emulsion should be one of the first things to be tried. This will kill the thrips whenever it hits them; but there will be many that are in between the

leaves that will escape, and, with those hatching out, it would probably take several applications; and as the insect flies quite readily it would probably come from other places. To pull and burn the plants when badly infested would check them; and especially would this be advisable early in the season, when they commence, as they did in the onion-fields of Lodi and Creston, in spots, and gradually spread over the field.

As the onion crop is such a valuable one it will pay to do more than ordinary work in fighting the pest; and the grower who watches closely and carefully for the first appearance of it, and then fights it from the start, will have the best success; but as it is an insect that has so many food-plants, it may be only a condition that forces it to feed upon the onion. It is evident that these insects seek succulent plants, and it may be that only in a dry season will it prove serious to the onion. Bulletin No. 27, of Iowa Experiment Station, contains quite an account of the insect, and can be obtained by sending for it. The address is, Experiment Station, Ames, Iowa. E. C. GREEN.

Wooster, O., May 3.

A visitor at our onion-beds here has just now, June 1, shown me that the midge or thrip has started in on our American Pearl onions. As we are now marketing them, however, they will not be likely to do us serious harm. Should the present drouth continue, however, I greatly fear a repetition of the troubles of last year. We are glad to get the facts given in both the above letters, but regret to know the insect has been doing mischief over localities so widely separated. In the onion-gardens at Creston, Wayne Co., O., they nearly ruined the crop. One of the owners, a Mr. Jordan, told me it was his belief they all wintered over in some old onions left in the ground over winter to produce sets. This agrees, you will notice, with the statement of friend Shockey. We have never found them on our Egyptian or winter onions; but they finish maturing their sets, usually, before the midge gets to be very bad. At the Lodi onion-gardens, a few miles from Creston, it has been for some years their custom to clear off every thing in the shape of vegetable growth from their grounds in the fall, and burn all rubbish. This, the men told me, was to prevent insects, fungoid diseases, etc., from being carried over from one season to another. Friend Shockey, you will notice, *also* suggests pulling and burning late in the fall. Can some one tell us whether flooding has ever been tried? The most successful celery and onion farms at the present time have arrangements for irrigation that could be modified so as to flood the land in the winter, without very much trouble.

OXYDONOR AND ELECTROPOISE.

BLUNDERERS AND PLUNDERERS.

The following is from the Rev. C. N. Pond, of Oberlin, O., who has been for many years connected with the Ohio Sunday-school Association, and is also recognized as a contributor to several of our religious periodicals. He is also well versed in chemistry and electricity. I have asked him to examine the advertisements and circulars, and give us his opinion. Here is what he says:

Dear Brother Root:—The documents you sent I have carefully looked over; also some directly from the Oxydonor office. The claims made are simply astounding. "Makes you absolute master of disease." "It will make you as absolutely independent of disease as if it did not exist." "It is *per se* more

than paramount to all else man's knowledge affords," etc.

From one of the Oxydonor tracts I conclude that the Electropoise is the same thing, but has passed into other hands, and Oxydonor Victory now fights its former self, "now in the hands and control of the Philistines who propose to make war upon humanity with that name." I mean that the entire matter of all the circulars of both indicates identity, but with a transfer and fight later. One of the publications particularly indicates the change.

The announcements of Electropoise and Oxydonor Victory are not founded upon any known principle of science or health. They lay claim to "natural laws heretofore unknown," and promise to cure almost every disease or afflicted humanity. The circulars and pamphlets bear the stamp of unmitigated charlatany, as devices to get money from needy sufferers, without rendering the slightest good in return. They do harm, because, though in some instances there is seeming relief, yet the inevitable effect in general must be to burden the afflicted by expense without profit, by raising hopes which can end only in disappointment, and by turning attention from actual methods of cure. Many honest testimonials can be obtained for any device whatsoever, because, from a given number of sufferers there are always some about to recover, and some who need simply to have their minds turned into a new channel of hope. Such was the case with so-called "Christian science," which was neither Christian nor scientific, and is the case with every patent nostrum palmed off upon the public. But as for any actual curative agency in Electropoise or Oxydonor, I should as confidently expect it in a tin whistle or a lucifer match. C. N. POND.

Oberlin, O., May 29.

We copy the following from the *Rural New-Yorker*:

HEALTH CURRENTS.

Four weeks ago, on page 316, we gave our opinion of the "electropoise" which is being advertised as a great "cure-all." By turning back to that page you will see that this device is a cheap little cylinder of nickel, filled with a mixture of sulphur and graphite, with a long cord connected with a garter. The estimated cost of the thing is under 50 cents, and the price is \$25. The points we tried to make were these: 1. The difference between price and cost is altogether too great. 2. We don't believe the sulphur and the graphite will set up any "action" that is going to do a sick person any permanent good. Our opinion, then, was that a nest-egg or a horse-chestnut carried in the pocket would prove just as scientific a cure. Early this week we received this note from the Medical Director of the company handling this device:

A lady brought us in an abstract from the *The R. N.-Y.* of May 11, containing an ignorant and annoying attack upon "the electropoise." "The electropoise" is not a fraud, no matter how apparently simple the contents and construction of the polarizer. When the polarizer is placed in cold water, etc., and the plate is applied to the warm surface of the bodies of men or animals, a thermo-electrical current is started, and enters the body. This current has a most remarkable effect upon the circulation, nervous system, and nutrition, thereby effecting unusual and easy cures in many diseases which can not be reached by the usual methods. I will call upon you.

Agreeably to his promise, this gentleman called, accompanied by the manager of the company—bringing an "electropoise" along with him. They admitted that our statement as to the make-up and cost of the device is correct—it is a 50-cent article sold for \$25.

Now, this is about the way we talked to these men: "Our present opinion is, gentlemen, that this 'electropoise' is a first-class 'fad.' You charge for it 50 times what it costs, and you make for it most extravagant claims which the ablest scientific men we know declare to be ridiculous nonsense. At the same time, we are always open to conviction. The *R. N.-Y.* is too big a paper to permit any bigotry or false prejudice to sway its opinion. While you can't buy our opinion for \$1,000.00, if you will give us proof that your claims are correct, we will help you place an 'electropoise' in the hands of every sick man in the country."

"That's just what we came to do," said the manager, "and here is your proof in these hundreds of printed testimonials from those who have used the 'poise.'"

"We don't care any thing about your printed testimonials. Admitting that these people think this 'poise' helped them, how do they know that it was

not some change of diet, or way of living, that did the business? What we call proof is a scientific demonstration that this 'force' you talk about, actually does cure, and an explanation of the way it cures and how it affects the system."

"We can't explain it. We only know that it does cure. We have a theory about it, however. Will you let us put one on you to illustrate it?"

"Certainly!"

A piece of ice was taken out of the water-tank. The nickel case of the "electropoise" was put on this ice, and the whole wrapped in paper. The garter at the end of the cord was fastened to the writer's wrist to the satisfaction of the medical director, and we all waited for the appearance of the thermo-electrical current. While it was preparing to start, the manager explained the philosophy of this new system of curing. Put in the simplest way possible, this is what we understood him to say:

When put in cold water, the sulphur and graphite in the cylinder start up some sort of chemical action, which is communicated by means of the cord and garter into the system of the person connected with the 'poise. Whether this "charge" is ordinary electricity or not, nobody seems to know. After entering the system, it very conveniently goes to the spinal cord, and thence through the nerves all over the body, quickening all the processes of digestion and assimilation, and thus (of course) curing disease by mending all the broken-down parts of the body and causing all the organs to do perfect work in nourishing and taking off wastes. Somehow or other, all the wise men of the ages have skipped this great principle heretofore, and most of the scientists now on earth are so envious and afraid that this "thermo-electrical current" will absolutely ruin the business of doctors, druggists, and undertakers, that they will persist in calling the "electropoise" a humbug, just as they did the electric brushes and other fads which flourished so 15 years ago, and have long since died out!

All this time I was waiting for that current to start. To cheer me along, the manager said that the current could cure catarrh, deafness, old sores of many years' standing, bony growth at the joints, that it would prevent consumption in its early stages, relieve dyspepsia or nervous prostration, and that it will make seeds and plants grow faster! Now, I am deaf, and have had catarrh; my fingers have been frozen, I have five bad scars on my hands; there is more or less malaria near where I live; I am always afraid that the baby will get hold of some tuberculous milk and drink it; I am sure to have a headache when I eat too much dinner; I am threatened with nervous prostration when I see how "Preservaline" and the "Creamery Shark" are permitted to advertise, and my lima beans simply won't start this year. Therefore you can imagine that I was mighty anxious for that "current" to start and put an end to these various troubles. But it didn't! I felt no effect whatever, and at last they took it off—putting me down, I fear, as a very tough subject. To tell the truth, I did expect to feel some thing like a mild shock of electricity, as I have no doubt something of that sort could be generated in this way. I simply did not feel it. We have now put the "electropoise" in the hands of one who has been an invalid for many years. He will give it a fair trial, and we shall all know the results. Needless to say, we have no faith in it whatever. Possibly we were wrong in saying that it is no better than a dried horse-chestnut, for undoubtedly there may be generated some slight chemical action. That this "current" will act all through the body, as these people claim, we do not believe, any more than we believe that skunk's oil will cure deafness because the skunk has a very acute sense of hearing. We have tried that remedy too.

But stop! Hold on now! We don't want you to go away thinking that we are down on all new things and influences that we can't fully explain! Not at all. We have had quite a little experience with a "thermo-mental current," and we have no objection to having every reader test it. To test it thoroughly, you must send *The R. N.-Y.* for at least one year into some family that does not now read a first-class agricultural paper. At this end of the line, we guarantee to make things sulphurous for all the rogues. In place of using graphite, we will make a great fight for the farmers' rights and try to put cool water on the hot-heads. The result of this combination will be a "thermo-mental current" of improvement which follows the mail right into that family, and works all through it, starting all the members up to better ideas of farming and living.

I may remark that the "Medical Director" alluded to in the above has seen fit to send me a very kind (?) letter; and he tries again to explain how it is that Electropoise acts. He admits they get \$25.00 for a 50-cent article, and says the scientific explanation of Electropoise is, that it acts in the same way as putting cold applications to the spine; but instead of applying the ice to the spinal column the polarizer is placed on a block of ice, and the "cold" runs along the wire to the wrist or ankle, and then to the spinal column. This explanation is quite ingenious indeed. But, unfortunately, science has never yet discovered a sort of cold or heat either that could run along a wire; then he modifies it by suggesting that it is "thermo-electric vital force" that goes along the wire. No scientist of the present day recognizes any such force, I hardly need remark; and yet these fellows keep right on robbing sick people.

\$6.50; 25 boxes, \$15.00. Special prices quoted on large lots and carloads. One gallon or 12-lb. square cans, with screw caps, \$10.00 per 100; or put up, 10 in a box, at \$1.40 for one box; \$13.00 for 10 boxes; 25 boxes, \$30. We have a good assortment of glass packages for retailing honey in. See our catalog.

WHITE BEANS.

I believe these always bring cash as surely as wheat and corn; and the prices have never been away down, like wheat and corn—that is, to my knowledge. The beauty of them is, they do better when planted, say the last of June, than at any other time (less liable to be buggy); and we usually have ground that can be cleared off about this time. The hurry of planting is mostly over, so we can put them in in good shape. We have never found any thing better than the York State Marrow and the White Kidney. We can furnish either at 15 cts. per quart; peck, \$1.00; bushel, \$3.50. If wanted by mail, add 15 cts. per quart for postage.

CRIMSON CLOVER.

We copy the following from a circular just received from Baltimore:

"It can be sown from June to October 20th; the earlier, the more pasture it will make. It germinates quickly, grows very rapidly through the fall and winter, blossoms in this latitude about May 1st, and is ready for hay about the second week in May, and matures seed from the first growth about first week in June. It can be sown after other crops are removed from the ground, such as wheat (when clover has failed to catch), oats, millet, or on any vacant ground. It is a very rank grower, some stools containing as many as 120 to 140 blossoms from one seed.

"It will grow and make a heavy crop of hay or seed on land so poor that the common clover would not make a stand; and if cut when in full bloom it will make the most nutritious hay known; or if turned under it will prove a most productive phosphate, increasing largely any crop that follows. We believe great profit would result to the farmer by sowing buckwheat and crimson clover at the same time. He could thus get two more crops a year than are usually grown. The buckwheat nurtures the tender clover-plant, and shields it from the summer suns; and when it is taken off in the fall it leaves the clover healthy and strong to make its growth."

The principal point in the above is for bee-keepers. On the same ground you can get a crop of buckwheat and a crop of crimson clover, both honey-plants. From what experience I have had with both, I have not a particle of doubt but that it will succeed. I intend to make a sowing of several acres myself. From 8 to 15 lbs. of the crimson-clover seed are needed per acre, and we are prepared to furnish it at the following very low figures: Two-bushel sack, \$7.00; per bushel, \$3.60; half-bushel, \$1.90; peck, \$1.00; pound, 10 cts. If wanted by mail, add 10 cts. per lb. extra for postage and packing. We will send 3 lbs. by mail, postpaid, for 50 cts. Every bee-keeper should try a little patch of it in his garden, even if he does not do any thing more. The spring and winter just past have, perhaps, been as unfavorable for this plant as any one for years past; and yet the reports, even as far north as we are, are sufficiently favorable to warrant at least a further test. Of course, it is not to be expected that all who sow it will get as great results as are claimed for it in many of the circulars sent out.

The *Practical Farmer*, of Philadelphia, for June 15, is devoted almost entirely to reports of crimson clover, and instructions in regard to its management. We think it will pay any one who is interested in the matter, and has had little or no experience, to send for this as a sample number. Address *Practical Farmer*, Philadelphia, Pa.

Did you ever! My Hubbard squashes now, June 13, have leaves as large as my two hands, and yet not a bug, worm, or insect of any sort has even so much as looked in the direction of that squash-patch, evidently. I have been watching them every night and morning, ready for the fight; but it looks now as if I should not have any fight at all.

CARLOAD SHIPMENTS.

Since last report we have loaded and shipped a fourth car to Barteldes & Co., Denver, Colo. We are loading a second car for G. G. Wickson & Co., San Francisco, and have export orders sufficient to make a fourth car for New York city.

A MILLION FEET OF PINE LUMBER.

During the last month we have bought, or contracted for, a round million feet of dry pine lumber for use in making hives, frames, boxes, etc. We have also contracted to furnish 10 or 12 cars of lumber cut for boxes for shipping celery, most of it grown in this county. We have for some time been cutting up pine lumber at the rate of over two cars a week.

MASON FRUIT-JARS.

We have a pretty good stock of Mason fruit-jars, bought before price advanced, which we will sell, where they last, as follows:

1 pint, 1 doz. in box, 65c;	6 doz. in box, \$3.50
1 quart, " " 75c;	8 " " 5.40
1 gallon, " " 85c;	6 " " 4.75

These are best jars, made with natural glass.

NORTHWEST TRADE INCREASING.

From the settlement for the month of May with H. G. Acklin, St. Paul, Minn., our Northwestern representative, we note with much satisfaction a decided increase in the trade in our goods for that territory. The amount sold during the one month was more than for the entire year of 1893, and nearly as much as last year's entire trade. This indicates either that the prospects for bee-keepers in that section are much better, or that they appreciate Root's goods and the convenience of being able to get them near home at catalog prices on short notice, as well as the service of our agent there. Doubtless both considerations help to swell the trade.

HONEY-PACKAGES OF ALL KINDS.

We have already furnished this season a great many thousand shipping-cases of various sizes, and several hundred boxes of glass to use with them. We are ready to supply thousands more in large or small quantities, as needed. Our cases are light, strong, neat, and well made. They include nails, and, if ordered complete, will include glass and paper to go under and over the sections in each case.

For shipping extracted honey the 60-lb. square cans can not be surpassed. After July 1st. in all the territory covered by the Western Classification, i. e., west of Chicago and Mississippi River, extracted honey in barrels, kegs, or cans boxed, will go at 4th class rate of freight. We are prepared to furnish 60-lb. cans, with 1½-inch screw caps, from New Orleans, La., St. Louis, Mo., Coneauat, O., or from here. Price of a single box of 2 cans, 75c; 10 boxes,

MISPLACED CONFIDENCE.

Without a shadow of fear farmer Trusty ran his traction engine on the bridge. The builder proved it safe by figures thus: four stringers across the ditch carry 1500 lbs. each, fourteen plank 500 lbs. each, equal to 13,000 lbs. While the coroner's son Trusty's remains, the builder skipped out. Maybe "figures won't lie," but they are sometimes juggled by ignorant or unprincipled men. Remember when figuring on fences the cross wires or pickets, like the bridge planks add nothing to the strength and the "stringers" of the Pige are doubly strong.

HONEY COLUMN.

CITY MARKETS.

BOSTON.—*Honey.*—Our market for comb and extracted is fully supplied, with a very light demand. Prices, comb, 14; extracted, 5@6.

E. E. BLAKE & CO.,
Boston, Mass.

June 19.

BUFFALO.—*Honey.*—There is very little doing in honey, and market is quiet. Fancy, 12@13; choice, 7@8. Extracted very quiet; but light receipts in market.

BATTERSON & CO.,
Buffalo, N. Y.

June 18.

MILWAUKEE.—*Honey.*—The demand for honey is very light. The season for fruit cuts off greatly the consumption of sweets. The supply is ample for all demands at this time. We continue to quote best quality 1-lb. sections, 14@15; second quality, 10@12; dark, 8@10; extracted, in barrels and kegs, white, 6@7; in pails and cans, 7@8; dark, in barrels, 4@5. Beeswax, 26@28.

A. V. BISHOP & CO.,
Milwaukee, Wis.

June 18.

CINCINNATI.—*Honey.*—There is no change in the market. Extracted honey is in fair demand at 4@7. Comb honey brings 12@14 for best white. There is a good demand for beeswax at 25@31 for good to choice yellow, with a scant supply.

CHAS. F. MUTH & SON,
Cincinnati, O.

June 18.

CLEVELAND.—*Honey.*—There is scarcely any demand for honey at present. No. 1 white in 1-lb. sections, is selling at 13; No. 2, 11. Extracted, No. 1 white, 6@8. Beeswax, 28.

WILLIAMS BROS.,
80 & 82 Broadway, Cleveland, O.

June 18.

KANSAS CITY.—*Honey.*—Supply light, demand light. We quote No. 1 white 1-lb. comb, 13@14; No. 2, 12@13; No. 1 amber, 11@12; No. 2, 8@10; extracted, white, 7; amber, 6; dark, 4@5. Beeswax, 22.

C. C. CLEMONS & CO.,
Kansas City, Mo.

June 19.

KANSAS CITY.—*Honey.*—Old crop of honey cleaned up; no new on the market. One-lb. white comb, old, 13; extracted, light, 6@7; dark, 4@5. Beeswax, 25.

HAMBLIN & BEARSS,
Kansas City, Mo.

June 19.

DETROIT.—*Honey.*—Best white comb held at 14; no sales of late. Strawberries always knock out honey. No new honey in sight yet, and but little old left. Extracted, 6@7. Beeswax, 24@25.

M. H. HUNT,
Bell Branch, Mich.

June 9.

CHICAGO.—*Honey.*—We are cleared up on comb honey, and there is some demand. The new crop will find a bare market. White comb brings 14@15; dark, 8@10. Sales of extracted are chiefly at 6@6½; Southern, 5@5½. Beeswax wanted at 28@30—very little selling below 30. We would advise shipments to meet present needs.

R. A. BURNETT & CO.,
163 So. Water St., Chicago, Ill.

June 18.

PHILADELPHIA.—*Honey.*—The honey market has begun to pick up some, with some call for new-crop comb. Extracted honey in fair demand. The market is all cleaned up of old comb honey. We quote new-crop extracted at 5½@6½, in bulk. Comb, 11@14, according to quality. Beeswax, 25@27.

WM. A. SELSER,
No. 10 Vine St., Philadelphia, Pa.

June 20.

CHICAGO.—*Honey.*—We report no inquiry for honey at present writing, but look for a good trade in August, as revival of business means prosperity for honey.

S. T. FISH & CO.,
189 South Water St., Chicago, Ill.

June 19.

SAN FRANCISCO.—*Honey.*—I quote extracted honey at 4½@5½ for light amber or white, respectively; comb, 1-lb. frame, 8@10. Beeswax, 26@27. The honey crop may be a good average one, although the bees are not working as well as was expected some time ago.

HENRY SCHACHT,
San Francisco, Cal.

June 13.

No. 1 extracted honey in 50-lb. pails at 7c per lb.—\$3.50.

J. B. MURRAY, Ada, O.

FOR SALE.—600 lbs. of comb honey, in 1-lb. sections, in 24-lb. shipping-cases, at 12c per lb.

EDW. SMITH, Carpenter, Madison Co., Ill.

BEE-KEEPERS.—We buy quantities best quality of comb and extracted honey. Let sample accompany price. We guarantee prompt pay, and give The A. I. Root Co. as reference.

J. A. BUCHANAN & SONS, Holliday's Cove, W. Va.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty.

J. P. IVY,
Secretary Bee-keepers' Association,
Phoenix, Maricopa Co., Arizona.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cloome (tinted), 6c. Samples, 8c.

BUSHEL BOXES.

The above cut shows our popular *all-slatted bushel box*. We have two other styles; one has slatted bottom and sides with solid ends in three pieces called the *slatted bushel box*. The other has solid ends and close bottom and sides, and is bound with galvanized iron and called the *galvanized bound box*. These boxes were devised by T. B. Terry for handling potatoes, for which purpose nothing could be handier. The potatoes are picked up into the boxes in the field and left in them till sold. Other crops, such as cucumbers, tomatoes, and apples are being handled in these same boxes. They are of such a size that two go crosswise in an ordinary wagon-box. Outside measure is 14x16x12 1/2 deep, and they hold a bushel of potatoes level full so they can be piled one upon another. The above cut shows two *all-slatted* boxes nailed up, and a bundle of 15 alongside; 13 of the 15 are in the flat, packed inside the other two, and nails of the proper kinds are included. The *slatted* and *galvanized bound* boxes are put up in the same way, except there are only 12 in a package instead of 15. Each package weighs about 85 to 90 lbs.

PRICE LIST.

All-slatted bushel box, per crate of 15.....	\$1 50
Slatted bushel box, per crate of 12.....	1 50
Galvanized bound bushel box, per crate of 12.....	2 10

In lots of ten crates, 5 per cent discount will be deducted. Price each, nailed, 15, 13, and 22 cents, respectively. A 20-page pamphlet called *Handling Farm Produce*, telling all about these boxes, mailed free on application.

WANTED.—To exchange 200 colonies of bees for any thing useful on plantation. ANTHONY OPP, Helena, Ark.

WANTED.—To exchange several good safety bicycles. Honey wanted. Send sample. J. A. GREEN, Ottawa, Ill.

WANTED.—To exchange 25-in. planer, power scroll saw, all iron; tenoner, and mortiser, for portable sawmill, or other wood-working machinery. Will give a bargain for cash. GEO. RALL, Frenchville, Trempe Co., Wis.

WANTED.—To exchange foundation-mills and honey-extractors for honey or wax. I. J. STRINGHAM, 105 Park Place, New York.

WANTED.—A foundation-mill, in exchange for other goods. L. L. ESENHOWER, Reading, Pa.

WANTED.—To exchange 40 colonies of bees in Simplicity bives, for Virginia land, or sell cheap. Also small farm to rent. GEO. G. GREEN, Lyons, Ohio.

WANTED.—Information regarding any locality in Southern Georgia, Alabama, or Florida, possessing good fall and early spring honey resources. Please address SOUTH FLORIDA APIARY Co., New Smyrna, Fla.

WANTED.—To exchange Shot-gun, Remington rifle, 4x5 kodak, safety bicycle, for foot-power saw, portable forge, etc. ROBERT B. GEDYE, LaSalle, Ill.

WANTED.—To exchange invalid and fracture beds in hard wood, "Perfection" brooders and "Perfection" bee hives, 8 to 12 frame capacity, contraction-device arrangement for comb honey—best in use; sections, foundation, frames, etc., for comb and extracted honey, pneumatic-tire safety bicycles, good cross of poultry, chicks or year-old stock, and pure breed, all kinds; also chicken and duck eggs wanted, to hatch. CHAS. L. HILL, Box 495, Dennison, Ohio.

German Hares!

Full-blooded, \$1.50 a pair; breeders. Write to me. E. W. SMITH, West Canaan, Ohio.

In writing advertisers please mention GLEANINGS.

Gray Carniolans and Golden Italians.

Our bees are *hardy, gentle, prolific*, and the best of honey-gatherers. One untested queen, 75c. six for \$4.00. All new customers can have one untested queen of either race for 50c. We do this to introduce our bees. We never saw foul brood or bee paralysis. Don't fail to try the Carniolans; they will surprise you. Descriptive price list free.

F. A. LOCKHART & CO., Lake George, N. Y.

Tested Queens by Return Mail at \$1.00.

I am devoting my apiary largely to the rearing of queens, making a specialty of tested Italian queens at \$1.00 each or six for \$5.00. These queens are of this year's rearing, and have been kept just long enough to know that they are good layers and purely mated. For several weeks I have been filling orders by return mail, and I am keeping a large number of queens in nuclei for the express purpose of enabling me to fill orders promptly. More than six queens (tested) will be sold at 75 cts. each, but such orders must be sent with the understanding that, while they will be filled as promptly as possible, it may not be by return mail, which will be the case with six or a less number of queens. The Review and one queen for \$1.50.

W. Z. HUTCHINSON, Flint, Mich.

Five Assistant Bee-Editors

Please cut out this whole ad. and sign and mail it to—
56 Fifth Ave., Chicago, Ill.

Please send to me the AMERICAN BEE JOURNAL for 3 months (13 numbers). At the end of that time I will send \$1.00 for a year's subscription, or 25 cts. in case I decide to discontinue. You will please address me thus:

Mich.

QUEENS. IMPORTED ITALIAN MOTHERS ONLY.

Untested, 55 cts.; doz., \$6. About 11 out of every 12 will make fine tested queens, and for gentleness and industry we defy the world to beat them. Safe delivery. Money-order office, Decatur. eiff

CLEVELAND BROS., Stamper, Newton Co., Miss.

A Full Line of Popular SUPPLIES

Always on hand.

1 lb. sq. flint jars, \$5.00 a gross, sent from this city. Untested queens, now ready, 75 cts. After July 10th, 3 frame nuclei and Italian queen, \$2.50. Discount on quantities. Catalog free.

I. J. STRINGHAM,
105 Park Place, New York.

One-piece Sections, Cheap!

In order to reduce stock, we offer No. 1 Cream Sections, 4x4x7 to foot, 1 $\frac{1}{2}$, 1 $\frac{3}{4}$, 1 $\frac{1}{2}$, and 2 inch:

1000 for \$1.50,
5000 at 1.40 per M.,
10000 " 1.35 " "

We also offer No. 1 White sections, 5 $\frac{1}{2}$ x6 $\frac{1}{2}$ x2, open on two 5 $\frac{1}{2}$ sides:

1000 for \$2.50,
5000 at 2.35 per M.,
10000 " 2.25 " "

G. B. Lewis Co., Watertown, Wis.

NON-SWARMING and NON-STINGING.

June 1 shall commence to ship queens and bees from my famous yellow banded strains. Queens, \$1.00 each. I never had a swarm of bees from one strain that has been in my apiary six years. No charge unless queens are satisfactory.

H. ALLEY, Wenham, Essex Co., Mass.

Golden Italian Queens by return mail, from a breeder obtained of Doolittle, which he selected and tested out of 1000, for his own special use; he said this queen is a better one than the

World's Fair Queen,

which was valued at \$50.00. Also

Italian Queens from one of A. I. Root's very best imported breeders; price of queens, untested, 55c; six for \$3.00; 12 for \$5.50; tested, \$1.00 each; 6 for \$5.00. No disease. Shall run 400 nuclei. Ask for free circular, which may be worth dollars to you if you buy queens. Safe delivery and satisfaction will be guaranteed in each and every case. 13-18ei

STRAY STRAWS FROM DR. C. C. MILLER.

ABOUT 52,000 bee-keepers, Mr. Cowan estimates, are in England and Wales.

ALL IN ALL I like the new Corneil smoker better than any other smoker I ever tried.

MORE GOOD PEOPLE are in the world than we sometimes suppose. Every little while I find some new ones.

A PRIME SWARM, says Doolittle, p. 484, "is often erroneously called a first swarm." Why "erroneously"?

HAY FEVER is what Somnambulist, in *Progressive*, thinks is the matter with me. Caught from sweet-clover hay.

ALFALFA is a thing that I supposed belonged outside of Illinois; but farmers in Northern Illinois are beginning to experiment with it.

PRETTY LATE to experiment with sweet clover this year; but you might still try cutting the big stalks to see whether stock will eat them when dried.

I CAN REMEMBER when clover yielded honey, but it wasn't last year nor this year. [Why don't you move over into the basswoods of Wisconsin, not far from you?—Ed.]

THE HIVE DISCUSSION should stop—if it continues to bring out good points—in about five years from now. [Do you mean it should or shouldn't stop? Don't catch on.—Ed.]

S. E. MILLER, in *Progressive*, thinks the form of hive, shallow or deep, doesn't matter much, because in a state of nature bees don't care whether a hollow log is perpendicular or horizontal.

J. B. HALL's PICTURE graces the pages of the *Canadian Bee Journal*. Friend Hall is very economical of ink, but he knows a lot about bees. [That's so. Too bad he doesn't write more.—Ed.]

THE UNION of the Bee-keepers' Union and the North American, shall it be or not? Better

discuss it thoroughly in print than to take time to discuss it at Toronto. [Yes, yes; the sooner the better.—Ed.]

GOLDEN QUEENS are offered by 11 advertisers in last GLEANINGS, and 11 others offer plain Italians. In the market for queens, as well as for comb honey, looks go a great way.

B. TAYLOR, after inventing and using for many years the sectional brood-chamber, takes away one's breath by saying in *Review* that he prefers the single brood-chamber. [Will he tell us in full why?—Ed.]

AFTER-SWARMS often have a number of queens accompanying. If instinct impels so many to leave, what holds any in the hive? or will all leave if all are out of cells? [Yes and no. No, I don't know.—Ed.]

THE *American Bee Journal*, in the person of Geo. W. York and wife, honored the Miller family with a visit June 12. Brother York brought along his usual stock of good nature, and we had just the best kind of a time.

HASTY tells in *Review* how to prevent swarming, and ends up by saying: "There, my bees bother me so with their swarming that I can't find time to tell you any more about how perfectly easy it is to prevent all swarming."

F. C. MORROW, taking pity on my homeless condition, has sent me some Arkansas honey. In appearance the honey compares with the best, and only needs improvement in flavor to bring price of gilt-edged section honey.

IN TAKING OFF honey-boards or any thing else with dauby burr-combs under, just raise up enough to break the burr-combs and then let down again. In an hour or so you can remove and find the burr-combs licked dry.

YOU MEDINITERS—no, I didn't say dynamiters—have never told us yet whether fastening wires by electricity was the right thing for us common every-day bee-keepers. [Yes, sir, if you can make it work. We have no trouble.—Ed.]

TIN PANS, HORNS, etc., are generally condemned as no good in making swarms settle. S. T. Pettit, one of the Canadian veterans, says

in *C. B. J.* that for 15 years he has not failed to make an absconding swarm settle by vigorously ringing two good cow-bells, keeping always in front of the leaders of the swarm.

GEODES are not a peculiarity of Tampa Bay, friend Root. I found many of them near Johnstown, Pa., in a deep cut made for the Pennsylvania Railroad. The water doesn't get inside the stone; the stone grows around the water.

DOOLITTLE has been misunderstood to claim that all five-banders have the same origin. He explains in *Progressive* that others have produced them from Syrian, Cyprian, and other bees, but he thinks all the five-banders of *Italian* origin have come from Mr. Hearn or himself.

CANADIANS have in general held out against wiring frames. The last *Canadian Bee Journal* touches the subject in a gingerly manner—doesn't approve, doesn't condemn—just says that the method of fastening wires by electricity works beautifully. On this side the line the wiring works beautifully too, whether fastened by lightning or not.

SAYS DOOLITTLE, in *Progressive*, "I have been in the bee-business as a specialist for the past twenty years, yet I feel that what I don't know of the business stretches out wide and vast, away out into the unknown; and I sit as a child at the feet of some vast problem, much of which is beyond my comprehension." Shake, brother Doolittle, shake.

THIS TROUBLES ME: Some report—particularly in Europe—that very strong colonies with unlimited brood room do nothing but rear bees to be fed, while other colonies with limited room for breeding lay up a surplus; and on the other hand we have reports where it's the unlimited room for the queen that goes with the surplus, and little brood room means little surplus.

FOR SHADE over hives standing in the sun, try this: Cut some grass—long slough grass if you have it; pile it on the hive six inches or more deep, and anchor it with two or three sticks of stovewood. Lift cover and all, and it will last through the season. But I want shade over myself as well as the bees. [So do I; but somehow it is not always convenient to have it so.—ED.]

A SMALL NUMBER have for years paid an annual tax for the benefit of bee-keepers in general. Is it fair to continue the Bee-keepers' Union in that way? Is there no way by which a large number can become interested in the Union and the North American? Large membership is the thing to strive for, rather than large attendance at meetings. In union there is strength. [How would it do to have smaller membership fees and a larger membership? I think it would be well to consider this.—ED.]

LARGE VS. SMALL HIVES.

WHY IT IS A QUESTION OF LOCALITY; A GOOD ARTICLE.

By J. E. Hand.

Editor Gleanings:—I have read with much interest the discussion on the subject of large v. small brood-chamber hives. This is a subject of vital importance to the bee-keeper, and one on which depends his success or failure in the production of surplus honey, perhaps, as much as on any other one thing except, possibly, location. I am persuaded it is all a matter of location, and length and time of honey-flow, that must ever decide this question of whether a large or small brood-chamber hive will give the best results in surplus honey. There can be no iron-clad rules laid down in regard to this matter, but it should be carefully considered and decided upon by each bee-keeper for himself, and according to his location, and time and duration of honey-flow, etc. Because a bee-keeper in Colorado has splendid success in the production of comb honey with a twelve or even fourteen frame hive, it does not signify that I should not have as good or even better success in my location with an eight-frame hive than with his large hive.

I will try to explain why it is altogether a matter of location. In the first place, every bee-keeper in the North (especially in Central Iowa, where I have kept bees for the past 12 years) knows that the hardest thing for us to do is to get our hives full of bees and brood in time for the white-clover harvest, which usually begins about June 1st, after which basswood opens about July 1st, and lasts from 5 to 20 days, according to the season, conditions of the weather, etc., 21 days being the longest flow I have ever known from basswood in Iowa; and as we do not have any surplus from fall flowers, our harvest closes with basswood, about July 10 to 15. Now, then, it is conceded by our most scientific apiarists that a bee does not become a field-worker until about 16 days old; and as it takes 21 days from the egg to the bee, then 37 days must elapse from the time the egg is deposited by the queen until it becomes a field-worker; hence all eggs laid after 37 days prior to the honey-flow which yields your surplus become worse than useless, because they become consumers instead of producers; and it has cost much honey and time of the workers to raise them, which might otherwise have been employed in gathering honey from the fields.

Now, then, 37 days prior to July 1st brings us back to May 23d; hence it will be seen that all eggs, in order to produce workers for the bass-

wood crop, which ends the surplus for the year, must be deposited by the 23d of May. Now, then, brother bee-keepers of Central Iowa, how many swarms would you have in 100 that would have eight frames, or even six, full of brood by May 23? After an experience of 12 years in Iowa I will venture to say that, one year with another, you would not have 25 hives out of 100 that would have even six frames full of brood by the 1st of June. Some seasons it is so cold during the fore part of May that it is impossible for the bees to care for so much brood at that season.

Now, in view of these facts how absurd it would be to advocate a ten, twelve, or fifteen frame hive for such a location! Why, any practical honey-producer can see at once that his surplus would go to fill up those empty combs in that brood-chamber, instead of going into the sections. As for me, I want a brood-chamber for brood, and it must be of a size that an average queen and colony of bees can fill with bees and brood in time to gather the white honey whenever it comes.

After years of careful study and experimenting along this line, with the above-named conditions to face, with eight and ten frame hives side by side, I have decided in favor of the eight-frame every time, for comb honey. This is for Central Iowa. On the other hand, in a location where the honey-flow does not come so early in the season, and continues all summer, an entirely different system would have to be practiced. For instance, in the San Joaquin Valley, in California, the surplus is gathered principally from alfalfa and fall weeds, and other flowers; in fact, nearly every thing that blooms yields honey to some extent; but their swarming is all over long before the harvest begins; and the more swarms they can get, the more honey they expect; and the parent colony has plenty of time to build up and get ready for the harvest from alfalfa, which continues to yield during the entire summer, and sometimes even to the first of November.

Now, in such a location as this it would be foolishness to advocate an eight-frame hive, for it is very important that the queen be coaxed to lay to her fullest capacity to produce workers for such a continuous honey-flow.

No, brother bee-keepers, this subject of large or small brood-chamber hives can never be governed by any fixed rules, but must ever be a matter of location, and time and duration of the honey-flow from which we obtain our surplus.

I will close by saying that I have no pet theory to bolster up, and will use the hive that gives me the best results in the production of honey, every time, if I can find it, and I think I have found it at last; and if this escapes the waste-basket I will at some future time tell the readers of this journal the hive I like best of all, and why.

J. E. HAND.

Wakeman, O., May 15, 1895.

[This article, it seems to me, states the situation exactly; and, no matter what has been said to the contrary, I think locality accounts very largely for the difference in opinion and experience. Indeed, it could hardly be otherwise. Competent and intelligent witnesses have testified in favor of the large or small hive, and from their standpoint and locality we can hardly question the soundness of their argument. Why, then, should these good witnesses differ? That little word "locality" explains it all. As I said in an editorial in our last issue, light is surely breaking. While some localities most assuredly require large hives, other localities want nothing larger than the eight-frame size, Langstroth; and our experience and orders show that a majority of bee-keepers are and have been situated like our friend J. E. Hand, as above.—Ed.]

BOX OR MODERN MOVABLE-FRAME HIVES.

WILL BEES STORE MORE HONEY IN THE AGGREGATE IN THE ONE THAN IN THE OTHER?

By C. Davenport.

In GLEANINGS for March 15, in one of the editorials we read: "The old statement that bees will store as much honey in an old nail-keg as in the most improved hive still stands practically uncontroverted." Now, I do not know that I can say any thing to controvert that statement; nevertheless, I do not believe that bees will store as much in a nail-keg, or, what is practically the same thing, a box hive, as they will in a modern hive, for I have kept some bees in box hives for a long time, and still have about 20 colonies in such. The largest yield I ever got from a colony in a box hive was about 80 lbs. This was secured by having holes in each side of the hive, over which boxes that would hold 20 lbs. each were fastened. There was also one on top, which they filled twice. I got them to work in these boxes by fastening pieces of comb in each one. This colony did not swarm that same season, which, by the way, was a good one; in fact, it was the best season for honey that I ever saw. A colony in a 10-frame hive stored 237 lbs. in 2-lb. sections—not by guess, but by actual weight. This is the largest yield I ever got from a single colony. I also made four new colonies from this one, and had them in first-class shape for winter. It was done in this way: This colony, which was a very strong one, got the swarming-fever just at the beginning of the white-clover flow. I did not wait for them to swarm, but removed all their brood, and gave them frames with only narrow starters of foundation in them. Now, I believe that, according to theory, a colony thus treated should not store any or work in sections until the brood-nest is full. But in actual practice a colony thus treated will, if the super is put on with one or two bait-sections, and the rest filled with full sheets of foundation, go to work in them at once—that is, in a good flow. I took those frames of brood with but very few bees on them, and divided them up into four hives;

and as soon as a few bees in each hive had hatched I gave them a laying queen, and then built them up by feeding and giving them frames with full sheets of foundation as fast as they could use them. At this time of the year it is warm, and no danger of robbing, and they will build up faster than one would suppose.

That same season from 40 colonies, spring count, I secured nearly 150 lbs. of surplus from each, and made a very large increase by the method I have just described. But perhaps I should say that all these colonies were very strong ones. They were the best ones that could be picked out of over 150. They also had a very good range, and at that time they were practically all the ones there were to work on it. But now if these colonies had been in box hives, would they have stored that much honey? I do not believe that they would—at least, it is certain that I could not have got them to do so.

Another old statement is, that one who keeps bees in box hives, and uses a starch or cracker box on top for a super, will get as much surplus. True, but not in as marketable shape as the one who uses improved hives. In this locality the former will not get as *much*, nor half as much; for, from some cause or other, bees in a box hive will not go up through a hole or holes in the top, and store as much honey in a box inverted over the same as they will in a super over a frame hive; for, with a very few exceptions, a small boxful on top makes them think it is time to swarm, and there is no way to prevent them that I know of—at least, no way either to prevent or to allow them to swarm, and still get a surplus by using box hives; for a swarm that is hived in a box hive will not fill a box on top at once, as they will a super where a frame hive is used. And now suppose that, from the same yard, the same day, we have two swarms issue that are the same size, and just alike in every way; say that we hive one in a small frame hive, the other in a box hive that is large enough to hold all they can possibly store, without having to go up into a box on top to work; which one will store more? I believe I can get the one in the frame hive to store at least a third more by using sections, with full sheets of foundation in them; for while, in some seasons, I think as some others do, that there is not much advantage in full sheets, as a rule I believe we can get a good deal more honey by using them. But I do not think foundation is the only thing that will cause the colony in the frame hive to store the most. I think that shallow supers and the tiering-up system enables or causes bees to store more than they will when they are given as much room all at once as would be necessary in the case just mentioned. But by keeping bees in box hives, and hiving the swarms from them in small frame hives, and using supers, etc., in the usual way, we can get

good returns from them provided they winter well, and then swarm at the right time. But, no matter what kind of hive we use, or what kind of bees we have, we shall sometimes lose one or more queens during the winter, and quite often a young queen will be lost when she goes out to mate.

The reader will now readily understand that a colony, in either case just mentioned, has at that time no brood from which they can rear a queen; and when a colony in a box hive loses its queen at such a time, it is a good deal more work, and much more difficult to remedy the matter, than it is when the same thing occurs in a frame hive.

Another old statement is to the effect that it is easier, and less work, to keep bees in box hives. I can not agree with this either. In fact, I think it is right the other way, even if we are keeping bees merely for pleasure, unless those who winter them outdoors can do so with less loss by using box hives. But even if this is the case, the difficulty I have just mentioned will, I believe, balance this. If it will not, there are many other serious disadvantages in trying to use box hives that surely will. Now, on the other hand, if we are keeping bees for pleasure, and also all the profit we can get out of them, I believe we can not only produce honey with less work, but that we can get *more* of it by using improved hives.

Southern Minnesota, June 5.

[Friend D., I do not think there is any conflict in our views, if I understand you correctly. Referring to the editorial in question, speaking of hives, I said, "Construction may enable him also to secure a little more marketable honey, and perhaps a little more in the aggregate. The old statement, that bees will store as much honey in an old nail-keg as in the most improved hive, still stands practically uncontroverted." You will see from the above that I do not say that modern hives would not give any more honey, nor that they would not produce more marketable honey; but I still think that a box hive, under normal conditions, having the same cubic capacity as a modern movable-frame hive containing section honey-boxes, will produce practically as much honey in the aggregate (not marketable) as any other.—Ed.]

BEE-KEEPING IN DIFFERENT COUNTRIES.

DOES IT BECOME LESS PROFITABLE AS CIVILIZATION ADVANCES?

At the recent convention of Ontario beekeepers, W. Z. Hutchinson rather argues that, as a country becomes settled and civilization advances, bee-keeping is likely to become less profitable. Under such circumstances we should probably feel justified in expecting that, in the long-settled countries, the number of hives kept would be very small. Such is, however, not the case. Germany has 1,900,000 hives; Spain, 1,690,000; Austria, 1,550,000; France, 950,000; Holland, 240,000; Russia, 110,000; Denmark, 90,000; Belgium, 200,000; Greece, 30,000. The

value of the annual production of honey and wax is estimated at \$14,750,000. There is, undoubtedly, reasonable ground to believe that some districts have greater advantages for the production of honey when first entered by the settler; but as a rule the flowers in a state of nature are in time replaced by another growth, artificial and natural. The increased skill of the bee-keeper, of course, overcomes some disadvantages. In Switzerland there are 2367 bee-keepers, possessing between them 10,509 stocks; this makes an average of less than five colonies to each. Very few possess as many as thirty; and in looking over a long list we find one having as many as 80 colonies. The bees will then be pretty well distributed; but imagine the number of colonies kept to the size of country. We find the number of square miles in each country as follows:

Country.	Square Miles.	Colonies per Sq. Mile.
Germany	208,027	9.00
Spain	200,000	8.45
Austria	115,903	13.37
France	204,000	4.65
Holland	12,648	18.09
Russia	2,950,000	1.00
Denmark	14,124	6.37
Belgium	11,373	17.49
Greece	25,000	1.20
Ontario	219,640	.74
Canada		.06

These countries practically consume their own production of honey. Owing to their age they are a more scientific people, and, owing to the small amount of earning, they have to be an economic people. Science and economy will teach people to consume honey. Very few of our Canadian people are aware of the value of honey as a food. Bee-keepers *must* exert themselves in this direction until it becomes the habit of the nation, when the custom will perpetuate itself. If we look at the value of bee-keeping in a country, it is inestimable. Europe produces nearly eighteen million dollars' worth from what would otherwise go to waste; and not only that, but in the fertilization of flowers it in all probability adds a similar sum to the wealth-producing powers of the country. Bee-keepers are surely fully justified in feeling that their industry represents nothing insignificant, and that it will stand on just as high a plane as they may place it. If they call it a trifle, a bagatelle, and the like, they must not blame the public for placing it at no higher standard.—*Canadian Bee Journal for May.*

A COLORADO LETTER.

FROM OUR OLD FRIEND M. A. GILL.

Editor Gleanings:—I have been much interested in your notes from Florida upon its products, its climate, and its people, and take this opportunity to say that I too have been rambling since you last heard from me. A person

coming from a humid region to an arid one is lost for something "green," and he generally turns his eye inward and thinks he sees the *greenest* thing yet—the people who leave a country whose crowning beauty is in its grassy slopes and leafy bowers, for the desert-like plains of the irrigable lands of the great West. But if he will stay until the water is turned on, and see the worthless-looking soil give up its burden of three or four crops of alfalfa in one season—see peach, pear, prune, or apricot give growth from six to ten feet in one season, he is generally spellbound and thinks, perhaps, that these facts should be added to the seven wonders. Truly this is a wonderful land of ours, and has a great variety of products and climatic conditions.

This is a good country for bees, both in this valley and up the Gunnison River, wherever alfalfa is raised in large tracts. Cleome also is found in large quantities, which yields large amounts of honey some seasons.

The one great drawback to bee-keeping in this valley will be foul brood, as it has got a start about ten miles from this city, and the slipshod bee-keeper, who abounds and seems to thrive in this country, will no doubt spread the disease faster than the vigilant eye of the inspector can detect and destroy it.

Bees at this time are breeding fast, gathering pollen from natural sources, and some honey from apricot-bloom. Peaches will be in bloom in two or three days, which will be followed by apple and pear. There are about 4000 acres of bearing orchard around this city, and it is estimated that as much more will be set this spring.

Western Colorado is earning a reputation for its large crops of fine-flavored fruit. I am having a mild attack of fruit-fever, and have taken as a remedy 5 acres of new land at \$100 per acre, and am setting it out to apples, pears, peaches, prunes, plums, nectarines, apricots, cherries, almonds, with strawberries and raspberries between the rows. I have purchased 25 colonies of bees, and will try to grow into my old-time number of 150 in Wisconsin.

While reading your experience with the two Indians in Florida I was thinking of mine here. Last Sunday my son Ernest and I mounted our wheels and went out to visit the Teller Institute. It is situated two miles east of the city. It was built by the government, and named in honor of Senator Teller, of Colorado, who took a great interest in promoting the enterprise. As we neared the school we found the large gate open; and as we wheeled into the campus we were soon surrounded by 126 Indian boys and girls who had just come out from their Sunday-school. Dinner was soon announced, when one of their number, acting as drillmaster, formed them in line and marched them in strict military order to the dining-room. Through the kind invitation of the superintendent, we followed. On reaching the dining-room each

took his or her place behind a chair at the dining-table; and at the tap of the bell each one stood with bowed head and reverently returned thanks for all the blessings that were around and about them. At another tap of the bell each took a seat and enjoyed a splendid dinner, gotten up by their own members who have charge of the culinary department. I said to myself I was thankful I lived in a land where the light of learning is being carried to those uncultured minds. I could see that each one, as he returned to his respective tribe, would be a nucleus for much future good. But the system to me seems yet incomplete; for, so long as their tribal relations exist, many will drift back to their former modes and manners, and can not accomplish the good they could if they were made full citizens, and given land in severalty.

In changing from Indians back to bees I will say I should think it would pay you or some one else to establish a branch house for the distribution of supplies here or somewhere on the western slope of the Rockies, as the freight is nearly as high from here to Denver as from here to Medina.

Bees have wintered well here, and are rich in old stores—a condition which is very desirable where bees fly nearly every day in the spring, but gather nothing.

I will say, in closing, that we are all in good health, and are nearly in love with this country, as we have good schools, good churches, and good society; and we hope to live so as to add to instead of taking from the good things to be found in this land.

Grand Junction, Col., April 8, 1895.

T SUPER VS. SECTION-HOLDER.

THE MATTER DISCUSSED FURTHER

By Dr. C. C. Miller.

I had hoped before this time to notice the editorial remarks on page 354. Perhaps you have fondly hoped, Mr. Editor, that I wouldn't. You say, "We boomed the T-super arrangement in our 1895 catalog harder than ever, putting in a nice wood cut. But our packers hardly know what it is." Yes, you made a nice picture of it, and all that; but then you said the section-holder is better. Now suppose you leave out the booming picture; don't say a word in praise of the T super; give high praise to the section-holder, and then make the remark that the T super is better than the section-holder. Then see if your packers won't know what the T super is. The point I'd like to have you see is, that all your booming isn't booming at all. You might just exactly as well not put the T super in your list at all, so far as beginners are concerned, as to put it there with picture and high praise, and then say, "We

consider the section-holder superior to any other."

I asked you to name a single feature of the section-holder better than the T super. To this you make no attempt at reply, except to say, "T supers were not very well adapted to the Dovetail hive without making supers of different lengths from the regular hive-body." That is, the reason that the section-holder is superior is because it looks better to have a super the same length as a hive-body. And for that matter of looks you advise beginners to use an inferior article! I believe in looks, but I don't want inferior bees just because they are handsome, and I don't want a super for looks. In the picture of the T super you have four pieces nailed on to make out the length. One of those pieces would work just as well as the four.

You say the single-tier wide frame "seemed to have all the advantages of the T super." Without mentioning anything else, let me ask whether the wide frame has the advantage that a section of any width can be used in it.

You disavow the idea of calling me an old fog; but then you make me tear my hair with rage by saying that I prefer the T super because I have become accustomed to it, and my habits of working fit it better than any thing else. Now look here; don't you know I was accustomed to the wide frames, and that my habits of working fitted them? I had raised tons of honey with wide frames, and had an invention of my own for emptying them that you thought worth describing and illustrating. I threw aside the hundreds of wide frames I had, both single and double tier, and adopted the T super. Why shouldn't I be just as willing to throw aside the T super for something better?

And while we're on that point, will you please tell us what advantage the section-holder has over the old wide frame? Certainly not ease of manipulation. The only advantage I can think of is that the tops of the sections are uncovered the same as in T supers. You have said that T supers are far better than wide frames, and now how can you say wide frames are better than T supers simply because the top-bars are left off? And now you talk about old stoves just because I won't go back to wide frames without top-bars when the length of the hive fits them.

Let me give a bit of testimony that has some bearing. One of the veterans, whose opinion I'm sure you would respect, writes, "Section-holders are far inferior to properly constructed T supers, and I congratulate you for voicing the fact." Another man writes, "I got the section-holders because Root said they were the best. I had used T supers in old Simplicity; but when they said section-holders—why, section-holders it was. But I must say I was never satisfied with them. . . . and I bought T

supers this spring to take the place of the section-holders."

In the *American Bee Journal* for June 6 occurs the question, "Which are better—T supers or wide frames without top-bars, called 'section-holders'?" Of the 24 who reply in the Question-box, some don't know; some think both are good; some think neither; one thinks section-holders better, and ten think T supers better. Pringle, Dibbern, and Doolittle prefer wide frames with top-bars. If I were obliged to give up T supers and go back to wide frames I should want top-bars on them; but I think I should want the frames deep enough so the top-bars would be a quarter of an inch above the tops of the sections.

EUCALYPTUS HONEY.

Considerable discussion has taken place with regard to the standing of honey from eucalyptus, in English and Australian journals. Much honey is obtained from eucalyptus in Australia, and the people of that country do not take it in the most kindly manner because the papers of England think the honey in question not suitable for the table. A letter from J. D. Ward, of Sydney, gives some light on the matter. He names eleven varieties, and says there are numerous others. Among them are a number of gum and box.

"Honey from box is generally considered the best, though that from iron-bark, shiny-bark, and some of the gums is excellent."

"*Not a single variety of eucalyptus yields a honey that has what is known as the eucalyptus flavor.* A few years back some bright genius mixed a small quantity of *eucalyptus* extract into a quantity of honey, and tried to sell it in England as Australian honey for its medicinal properties. Of course, it was unfit for the table, and of course it gave Australian honey a bad name. It would have been all right if sold as a medicine, and labeled '*Eucalyptus and Honey.*'"

"I am sending you a sample of honey I extracted last month (February). It is mostly iron-bark, but honey gathered entirely from iron-bark is better."

"Eucalyptus extract is a volatile oil, double-distilled from, I believe, the blue-gum only, though I have no doubt it could be obtained from other eucalypti. It is used here very largely in the treatment of colds, sore throats, etc. I send you a sample; and when you get it, if you put a few drops into half a teaspoonful of your clover or basswood honey, and stir it well, you will have eucalyptus honey that is 'not fit for the table.'"

The bottle of honey Mr. Ward was kind enough to send was, unfortunately, broken on the way, so that I had not a fair chance to test it. From the little I could scrape up to taste, I should say it was somewhat in flavor like a sample of our fall honey, not equal to the best, but by no means unfit for the table. But, as I

said, I could not judge fairly; and it is possible it may have gained a flavor from the wood of the box into which it ran. The eucalyptus extract, while it might rank high as a medicine, has a very vile flavor for use on the table.

Marengo, Ill.

[There, Dr. M., I am glad you have handled me without gloves, because it gives me a chance to "talk back." Well, in the first place I would call you "old fogey," but you are in pretty good company, and I fear I might have a buzzing of bees or something of that sort around my ears.

Now, then, as you have asked point-blank questions I will try to answer them point-blank. In the first place, in the previous issue I took back the word "booming," so I will acknowledge I am knocked out there to start on; but when you raise the question about leaving out the picture, and not saying a word in praise of the T super, praise the section-holder, and then say the T super is better, and that our packers would not know what it was—well, I just won't give in. I will tell you why. You go on the bicycle as I do among bee-keepers, and see how section-holders, modifications of them, are used—that is, topless wide frames, and you would conclude there is a very large following who would have them, no matter what we said of T supers. We are now pushing self-spacing frames, and recommending them in preference to loose-hanging; but there are thousands of bee-keepers who will not have a self-spacer, no matter what we say in favor of them. According to your reasoning every bee-keeper, nearly, ought to be a user of self-spacers because we say they are better.

Now, you ask me to name a *single feature* of the section-holder better than a T super. I will name several of them. 1. In some localities it is desirable to shift the outside row of sections to the center, and *vice versa*. You can not do that practically with the T super without a good deal of picking and fussing. Section-holders permit of handling the sections in lots of four at a time, with perfect safety. True, you say you can pick up four sections from the T super; but you must pick them up by the adjacent corners—not an easy thing, by the way, when a T super is full or partly full of sections.

2. Again, loose T tins are more or less of a nuisance, and once in a while get bent; and to have them fixed stationary is not very satisfactory.

3. The T tins take up a little space between each section; and if sections are inclined to be diamond-shape, one set of sections will point toward each other, and another set away from each other, making a difference of from $\frac{1}{8}$ to $\frac{1}{4}$ inch, depending upon the amount of play in the super. Oh, yes! you say you can and do obviate that by putting in little strips of separator stuff to fill up the cracks; and here, again, you have three little strips of separator stuff and three loose T tins to handle over every time you handle sections. But the facts prove that the very great majority of T-super users do not use those little strips of separator stuff, or any substitute; hence nearly all sections filled in T supers are more or less diamond-shape. As the section-holder does hold the section square, the average run of bee-keepers using such will have square sections that will crate.

4. But a very *important advantage* of the section-holder arrangement (not possible practically in the T super) lies in the fact that separators full width may be used, covering section-holder edges and the upright edges, and

horizontal edges of the section, not scored out for bee-ways. This, taken in connection with compression by means of a follower-board and wedge, closes up all little spaces; and the consequence is, the edges of the sections are practically free from propolis-stains, and do not therefore require scraping to the same extent that sections do from T supers. Indeed, there is no comparison. This is no theory. The honey we buy, produced in section-holders, looks better, so far as the propolized edges are concerned, than that produced in T supers. I can (or think I can) spot a T-super section every time. This compression idea I got from Mr. Manum, in Vermont, and from some other practical bee-keepers in York State, while on my first bicycle-tour. When I arrived home I incorporated it in the section-holder device as as soon as possible.

5. The great mass of bee-keepers (and that means, I think, the great majority) do not scrape the sections before putting on the market. Now, I do not guess or think, but *know*, that filled sections from section-holders with wide wood separators, and compression, present a far cleaner appearance, so far as propolis is concerned, than do those from T supers. Our position as buyers of comb honey, from all over the country, from large and small producers, places me in a position where I know whereof I speak.

6. Again, T supers require some rather nice or complicated methods of emptying them out—see our A B C, and Year Among the Bees. The section-holder arrangement may be emptied by simply removing a wedge or tightening-strip, and then all are practically loose. By turning the section-holder upside down, and pressing the two thumbs near the center, all propolis connections are broken, and the sections are loose. The manner of emptying sections out of *section-holders* is self-evident; but out of *T supers* is not so evident—at least, it has been necessary to have nice engravings made, showing each step; and as good and clear a writer as the author of "A Year Among the Bees" did not make his plan of accomplishing the result plain to me without photos.

No, sir, Dr. Miller, there are hundreds of bee-keepers who would prefer the section-holder arrangement for the reasons I have given above. It is able to stand on its own bottom; and if what I have said by way of comparison is true—and I am sure there are lots of bee-keepers who will back me in this—we are perfectly justified in saying what we firmly believe, that the section-holder arrangement is better. You evidently feel that I do not think the section-holder is quite as good as the T super, and that, because of the mechanical convenience we boom it in preference to the other, and for no other reason.

As to the matter of looks in the T super, there is not one customer in a hundred who would accept it if the cleats were all on one end as you suggest. The outside cleats on both ends are intended in lieu of hand-holes, and for the purpose of giving a symmetrical and finished appearance to the super when placed up on a hive of greater length.

You ask if I don't know that you are accustomed to the wide frames, and that your habits of working fitted them. Let me ask another question. Are you accustomed to the section-holder, and do your habits of working fit them? You are accustomed to handling hundreds and hundreds of T supers against five or six of the section-holder arrangements. How can you fairly appreciate the section-holder.

This is a question that could be argued a good deal; but the individual preference, and that old bone, "habits of working," will keep

those that have been using the one and the other largely in the line that they have been accustomed to. Now, doctor, don't you intimate again, that we recommend the section-holder because, perhaps, from a mechanical point of view, it may be more convenient, or—or—I'll jump on that "bike" for Marengo, and, arriving there, "talk it out" or chuck you in that stove that you are saving for me.—[ED.]

CALIFORNIA ECHOES.

By Rambler.

"Overeating shortens a man's life." So says truthful Dr. Stray Straws. And why does a man overeat? The dear well-meaning cherub who engineers the cook-stove thinks her "hubby" must have all the fancy dishes going—spiced, larded, sweetened, frosted; and the poor stomach, unless of cast-iron qualities, soon breaks down.

Now, I will go you one better, Dr. M. Half of the modern cooking is a waste of time and material, and a delusion and a snare. Remedy—come out to California, and bach on a bee-ranch, where you can cook your own Aunt Sally pancakes, lunch on crackers and cheese, and dyspepsia will fly away.

We are glad to note two arrivals of bee-men who propose to make California their future home—the Hon. J. M. Hambaugh of Illinois, and Mr. H. Y. Douglass, of Texas. The latter thinks California has charms even greater than the much-lauded Lone Star State. Well, he is not the only one to entertain such ideas.

Mr. G. K. Hubbard, of Riverside, Cal., has produced over one ton of orange-blossom honey. It is a strictly fancy article, neatly labeled with labels from the "Home of the Honey-bees. There is no slipshod management about Mr. Hubbard's apiary, and a few more such expert bee-keepers would have a marked influence upon the value of our products in the markets.

The California honey-yield will not be so large as the opening of the season warranted us to expect. The greater portion of the month of May was cool and foggy. The flowers were abundant, but the elements were against the secretion of nectar, and also against the free working of the bees to secure the nectar secreted. The honey already secured is of fine quality, water-white, and well ripened. There will be many carloads to ship, but we predict that the yield as a whole will not be as large as it was in 1893. Many considered the yield then as only a half crop.

After studying every phase of the Heddon-Danzenbaker controversy I have come to the conclusion that Mr. Heddon ought to pay Danzenbaker a fair sum for inventing a hive. The D. hive will probably not cut much of a figure against the H. patent. Its chief utility so far consists in being a good advertisement for the latter, and good advertising should be paid for.

RAMBLE 135.

OFF FOR EUREKA.

By Rambler.

spent Sunday in Blocksburgh; and though it is a town of about 200 population, and has a thriving school of about 100 scholars, there are no gospel services, no Sunday-school, no church. The stores were open, and seem-

ed to do a thriving business during the day, and from early morn until late at night the two saloons were well patronized. During our sojourn in town we noticed one citizen in particular who was a daily patron of the saloon. He was at one time a large owner of land, sheep, and a squaw; he had reformed from his squaw condition, married a white woman, and now had a family of four bright children. Hard times came knocking at his door, and a mortgage upon his property had caused a relapse of his moral condition, and the cup was his daily solace. Result, a careworn wife and shame-faced children. The many elegancies in the home gave evidence of a woman of taste and culture; the piano stood unopened; there was dust upon the music-rack; no merry songs ascended from that home now. It was tears and moans and prayers. The house could not have been more sad with crape on the door. Every day at about noon the father returned from the saloon, blear-eyed, unsteady of step, and maudlin of speech; and he spent the afternoon in drunken lethargic sleep. Thus again a bitter picture of the rum-traffic thrusts itself upon our attention. Perhaps a little church here, a little Sunday-school, a little exhortation, a little prayer, even if it save not the father, would save the sons from the ruin-strewn path of the drunkard.

Another character appeared upon the streets one morning. He was a tall spare man—a long old-fashioned muzzle-loading shotgun in his hand. He said he was a bumner by trade, but just now he was acting as a guide to a party of hunters bound for Mad River. He was known as "Dad," and it was "Dad, shall I do this?" or "Dad, shall I do that?" He was the most thoroughly daddied man I ever met. He had no end to deer and bear stories. His gun, his pack-mule, and his little dog, were all special favorites. The last glimpse of his outfit was when the whole party marched jauntily into

the forest, confidently expecting to return with a ton of jerked venison.

The climate and capabilities of this portion of California found a staunch advocate in the doctor and druggist. The very best of apples and pears can be grown here. Apple-trees, five years after planting, would yield five barrels of fruit, so the doctor stated; and the pears grown here are immense and luscious. The doctor believed the apple would eventually prove more profitable here than the orange in the south. He desired to make an impression upon us, for he evidently thought we three would make thrifty settlers. The old-timers there were too lazy to work; and when they wanted meat all they had to do was to go out into the brush and shoot a deer or a wild hog. Game of all kinds abounds—quail almost in town; rabbits plentiful. Any bee-keeper wishing to keep bees in a small way, and live a retired life, can here find just what he wants, and land at \$2.00 per acre.

We three finally bade the doctor, the shoemaker, the blacksmith, and Mayor Block, good-by, and next camped upon Van Deusen River. When we arose in the morning, Bro. Pryal was missing. We knew where to find him, however; for out in the middle of the river, mounted on a rock, with pole in hand, in that favorite position of his; and how patient, and how satisfied—with bites!

We three are now passing rapidly toward Eureka, on Humboldt Bay; and what a grand drive among the mountains and the redwoods! We might say fifty miles of forests. Of course, there was now and then a space of brush, or a stage station, or a lone ranch; but now we came to the dense redwood forest, and for twelve miles we were overshadowed by the immense trees—trees fifteen feet in diameter; tall trees 150 and 200 feet or more. We three traveled leisurely, and stopped often to admire the forest. Now and then there would be a little break in the forest, and a wood-chopper's cabin or a place to make split shakes would appear.

"DAD."

We were told by the shoemaker, that, no matter how hot the weather outside the forest, we would put on our overcoats when we had gotten into it. The tops of the trees were so far

up, and the foliage so dense, that but a small amount of sun heat penetrated to the ground; and though we did not put on our overcoats, we felt a decided depression in the temperature. And how we three did appreciate the dim aisles of the woods! There was but little animal life

as a side issue and as a means of recreation, though Mr. B. is an expert photographer, having followed the business for several years.

A swarm of bees came to Mr. Brush, and, like all ingenious men, he set to work to devise a hive; and though Mr. B. had never been in-

terested in bees, had never read a journal or a book upon bee culture, yet our photo shows a veritable up-to-date dovetailed hive. The frames are not Hoffman, and the surplus sections not 1-lb.; but the nearness to modern ideas is quite surprising. The dovetailed idea was stumbled upon by using Winchester cartridge-cases, and the frames were made to fit them. The busy bees had filled their hives, and Mr. Brush is looking forward to the coming year with expectations of a bountiful harvest.

As to the sources of honey, we did not see much that would encourage a specialist. Our observations were made in October, and, not seeing the sages, the honey-flora must consist of spring flowers. Mr. Brush is

not a bachelor, but has a well-ordered household, is a leading factor in the community of Hydesville, and a staunch advocate of Humboldt Co. as a healthful and profitable portion of California; is a dyed-in-the-wool Republican, and a handy man to have in the community.

E. A. BRUSH AND APIARY.

in these dense shades, and the silent forest gave back only the echoes from our passing wagons.

We three bee-men would now and then see the busy bee, when we came to openings in the forest, indicating that some of those tall hollow trees were occupied.

Our redwood experiences, however, came to an end, and new experiences in a civilized community occupied our attention. In Hydesville we three very fortunately found a vacant photograph studio, several rooms adjoining, pleasant people downstairs. We three took possession, and for six weeks we sojourned in this pleasant town.

The observations of us three soon discovered the bee-keepers in town. The old box hive and let-'em-alone policy prevailed, and the number of colonies was not excessive. There were no complaints from the fruit-men, and we heard not a word about overstocking the field. The leading bee-keeper of Hydesville was Mr. E. A. Brush. Our acquaintance with him commenced in a peculiar way. While Mr. Wilder and I were trying to get a photo of the public school, and just as we pressed the button on the school, Mr. Brush, who lived across the street, and possessed a camera, pressed the button on us. We were oblivious of the fact until a couple of days afterward, when we were surprised and pleased to see the photo.

Mr. Brush is the ingenious man of all that portion of the country. Watches, jewelry, and guns are neatly and expeditiously repaired, and photographs taken. The latter is pursued more

CLIPPING QUEENS' WINGS.

Question.—Is it advisable to clip the queen's wings? What has been the experience with such queens? Are they more likely to be superseded by the bees than those having perfect wings?

Answer.—In nearly every apiary, where the manager can or is expected to be present during the swarming season, I should advise the clipping of all laying queens in the apiary; in fact, I should as soon think of going back to box hives as to the managing of an apiary where the queens have their wings so they could fly out with the swarm, where I was working the same for comb honey. I said, "in nearly every apiary." Why I said this was, there are a very few localities in the United States where ants are so thick on the ground, and about the hives, that it would not be safe to allow the queens to be out on the ground for any length of time, else they would be killed by

these same ants. But as such a place or places are rare exceptions, it would be safe to say that I would always clip the wings of all queens in the apiary as soon as laying. Some seemed to think that queens with clipped wings give far more trouble at swarming-time than do those having their wings; but I can not think that such have had much experience with clipped queens; for with myself I would rather manage three swarms where the queens are clipped than one whose queen can go with the swarm. Especially is this the case where there are trees in or about the apiary, whose height exceeds 15 feet; for where there are tall trees near the apiary the swarms alight so high that it is often more than they are worth to climb for them, while the clipping of the queens' wings does away with this climbing part entirely, if no after-swarms are allowed to issue. Without going over the whole ground regarding the advantages arising from clipping, it can be expressed thus: Clipping the queen's wings prevent swarms decamping, as a rule; saves the climbing of trees after swarms, or the marring of those trees by the cutting of limbs or the bruising of the same; makes it easy to separate the bees where two or more swarms come out in the air together; facilitates the hiving and managing of swarms, and gives the apiarist perfect control of the apiary during the swarming season. As to their being more liable to supersedure, an experience of 25 years says there is nothing in the claim put forth by some that such is the case; for during that time I have had very many such queens remain the profitable heads of colonies for three, four, and even five years. My impression is that superseding, as a rule, is caused by failure on the part of the queen as an egg-layer, and not on account of any clipping. I, unfortunately, in clipping a queen purchased of A. I. Root, away back in the latter seventies, clipped off a whole leg and a foot off another, besides the wings; but this seemed to make no difference, as she did her duty well for over four years, and then lost her life by carelessness on my part.

CHANGING QUEENS AT TIME OF SWARMING.

Question.—Wishing to Italianize my bees I have thought that it might be done by changing queens at time of swarming; therefore I would ask if, in hiving either one or two swarms upon the old stand, or in a new location, would it be safe (by removing the queen or queens) to let a strange queen go in with the swarm?

Answer.—The changing of queens, upon the hiving of any swarm of bees, in any place, is liable to "raise a rumpus;" and especially is this the case where the swarm is hived upon a new stand; for in this case the least disturbance or dissatisfaction will send the swarm whirling back home. The chances of failure are too great for all practical purposes, with a single warm hived in a new location. Where two or

more swarms cluster together, if the new queen is placed in a large cage made wholly of wire cloth, so that the bees can get near the queen in large numbers, and the cage hung with the clustered swarm for half an hour or so till they call her "mother," then this large swarm can be hived where we please, and the queen allowed to run in with the swarm; and, as a rule, all will go well; but as very few wish to hive two or more swarms together, and as their coming so it is possible to do this is not very frequent, did we so wish, this also is hardly practical. The chances are better where the swarm is hived in a new hive on the old stand, or allowed to return, where you have the old queen so you can control her on account of her having a clipped wing; but even then they will sometimes become so dissatisfied that they will hunt up the old hive, unless moved some distance from its old stand, and all or nearly all go back to it, or go into hives all about the yard, where in many cases they will be killed. If the above large cage is used, placing the cage over the frames before the swarm returns or is hived, and the queen allowed to remain in this cage for a day or two, the chances of success are much increased. On the whole I would not advise the changing of queens during the swarming season in any way or by any plan, for I find it to be much more annoying to try to change queens with colonies about to swarm, or with those which have lately swarmed, than with any others, or at any other time of the year; and, besides, a failure more often results.

COLOR IN BEES THE LEAST.

Question.—Did you read what the editor of GLEANINGS said on page 393 about the color of bees? If you did not, please do so now and then turn to "Bees, Queens, etc.," in their illustrated catalog and read how the Roots charge more for queens of a yellow color than they do for queens of darker hues, thus putting a premium on the yellow ones. Are they not putting color to the front in this way as much as any one? How do you reconcile this with E. R. R.'s statement that he would not give color even a favorable position? If the darker bees are the best, why not charge more for them and thus build up the best bee in the world, while S. E. Miller's owl shouts, "Who-who-who-are you?"

Answer.—It is probable that the friends Root understand what they are about, hence I shall not try to reconcile the apparent discrepancy which the questioner points out—only saying that, perhaps, friend E. R. R. will enlighten us on this matter. While on this matter of color I wish to say that this very item gives the main "handle" we have in the improvement of any stock. Mr. Miller asks, "Are the prize-winning Jersey cows the prettiest cattle?" To this I answer by asking, "Do the judges awarding the prizes select the prize-winning Durham-cattle color to award the Jersey premiums on?" All

are cattle, and it is the *color* and make-up of the Jerseys which give them the name of Jersey cattle, and whatever there is good in them. So all are bees, and it is the *color* and make-up of the *golden* bees which give them all the good qualities there is in them, and by this color I have been enabled to select a bee which has given me a greater profit than any other. If others wish to select any other bees by their color, they are at perfect liberty to do so; and I see no need of insinuating hard things against any bee-keeper who selects bees by the color *black* because he thinks they are the most profitable.

[Why, friend D., it seems to me your questioner does not take in all I have said. Evidently, the writer of said question is a little nettled over my position toward the yellow-banders, and, like all opponents, fails to give all of what the other side said. Now turn to our catalog, page 29, and read: "While we do not regard them [that is, yellow untested queens] as any better for real business, there are some who go in for beauty." And, again, under the paragraph headed "Select Tested," after describing the progeny as large and yellow, this sentence occurs: "The progeny of these queens, for real business, will probably be no better than those from the ordinary tested." This answers the whole question, it seems to me; and the mere fact that we charge more for them is no evidence that they are better, in the face of such statements concerning yellow-banders, as above given. There is nothing to reconcile at all. The very fact that we charge less for the leather stock, and more for the yellow, would induce most people to purchase in the interest of their pocketbook when it is distinctly stated that the cheaper queens are just as good. Another thing, we had to charge more for the yellow stock, because there was such an insane rage for the yellow at the time the catalog was written that we would have had no sale for the leather-colored stock.—Ed.]

WAS LANGSTROTH THE INVENTOR OF THE
MOVABLE-FRAME HIVE?

Mr. Root:—I send you this. Perhaps it may be old to you, but I send it for what it may be worth.

A. D. P. YOUNG.

Ashtabula, O.

The popular notion that Langstroth was the inventor of movable frames for bee-hives is an error. Such frames were known in Germany 30 years before 1852, the date of Langstroth's first patent. In 1843 Baron von Berlepsch made use of movable frames, and he refers the idea to a man named Prokopovitsk, who employed it in 1841. Evidence to prove this statement is obtainable at the Patent Office in Washington. Furthermore, in a book published in London in 1841, entitled the *Natural History of the Honey-bee*, on page 300 may be found a description of comb-frames hinged like the leaves of a book. By the way, the notion held by bee-farmers, that the dovetailed method of constructing hives has been patented, and must not be imitated, is a

mistake. It has never been patented, and is a common right. Anybody may manufacture such hives.

[Strictly speaking, Langstroth was not the inventor of movable frames; but he was the inventor of the first *practical movable frame—something that was of use to the world*. The leaf hive of Huber, while the frames were, in a certain sense, movable, was not a practical hive, and one would about as soon have regular box hives without movable frames. There is a certain person who seems determined that Langstroth shall have no credit for the great strides he made in bee-keeping, and that person is C. J. Robinson, who was cotemporary with Langstroth when he was doing his best work. I do not know whether the clipping above given came from C. J. R. or not, but it is all of a stripe; but I do know that Mr. Robinson *appears* to be jealous of Mr. Langstroth. Such kind of writing at this time is in keeping with the claims of those who say Columbus did not discover America simply because he found men here when he landed, so the natives must have been ahead of him. He was the first man who discovered it in such a manner as to make it of *use to the rest of the world*, and in a way that seems just now to be durable—something the Icelanders did not do, although they *touched our shores just as Huber did movable frames*. Far be it from me to detract from Huber. He is already covered with glory; but if he were living he would want none of the just credit belonging to the father of American bee-keeping.—Ed.]

DOUBLE-STORY LANGSTROTH HIVES.

I read in GLEANINGS, May 1, a report by friend Nash and Mr. N. E. Doane about 10 and 16 frame hives with large colonies of bees producing large quantities of honey. I should like to say a few words also, which I know will please you. I started in April, last year, when I ordered that Cowan extractor from you, with only three hives; that is, to put two more stories on top of those hives as an experiment, so as to test the quantity of honey that those three colonies would gather. What was the result? They filled 16 frames in ten days, with nice clover honey. Well, when that extractor arrived on Saturday evening, that next day I gave it a trial. It worked like a charm. I extracted between four and five gallons of honey from one hive which had a half-story on; but those three hives where I put those two one-story hives on top gave me eight or nine gallons apiece inside of two weeks. Yes, I side in with friend Nash and friend Doane. This year I tried it again, and I received my reward from those same hives as last season. I shall hereafter run all my hives on that scale. It is paying. There is nothing like it that I have found. Of course, we must keep our colonies strong—that is, they must have a good laying queen. I have mostly hybrid bees. It is very hard to get queens mated with Italian drones, on account of so many parties having a few hives for their own use. Then another obstacle is, the woods are so close to our doors; but nevertheless my bees give good results in gathering honey.

GEORGE SCHAFER.

New Orleans, La., June 1.

THE RIGHT AND WRONG KIND OF FRAME-SPACERS.

THE WANDER SELF SPACING FRAME HIVE.

By Eugene A. Wander.

The body of the hive can be the same as any in use. The hives with which I experimented are of the Quinby, Langstroth, and Gallup types, with the addition of slideways, which are affixed at opposite sides. The frames may

also be those used in other hives with the addition of pins or screws driven or screwed in at their respective places in end-bars; viz., two in each end-bar about one inch from the end. The slideways are so adjusted that they slide smoothly and easily. Closed frames with comb can easily be planed off on sides, and used. I prefer the slideways made by cutting parallel mortises in inside of ends of hive-body, and fastening flat strips of tin to the ridge remaining, as will be seen below.

It is the most perfect and easy hive to manipulate that I know of, being able to do almost every possible thing with it with ease, such as moving or shipping without loss of time in preparation, and possibility of fixtures getting loose and killing the bees; also perfect spacing through the center, top, and bottom, and at sides of frames; reversing frames or hives; ease in withdrawing or inserting frames without destroying bees or danger of killing the queen;

the frames do not have to be pried loose in taking out, and most other features which will readily be recognized upon examination. Every thing is interchangeable. The little extra in cost of making the hive is soon balanced by profit, to say nothing of the pleasure of handling it.

EUGENE A. WANDER.

Hartford, Conn., May 18.

[Perhaps I ought to say that spacing-devices that are part and parcel of the hive, and not of the frames themselves, have not proven to be very popular among bee-keepers. I have no doubt that friend Wander can remove the frames; but he by his plan loses some very important advantages. For instance, suppose he wants to examine the brood-nest. He desires to take out an outside frame, we will say, full of honey. In order to put in the center of said brood-nest an empty comb, and yet keep all the rest of the combs in their same relative position, he must remove at least half of the frames, then put each one back in a notch or trough next to the position it formerly occupied, in order to give frame-space in the center of the hive. Suppose, now, the spacers were a part of the brood-frames themselves. We simply remove the outside frame containing honey, and shove the whole four or five frames, as the case may be, over *en masse* at one operation, and in less time than friend Wander can remove a single frame. There is now space on the center of the brood-nest to insert an empty comb for eggs. I have mentioned only one disadvantage; but there are others, though it is hardly worth while to give them, and I know of no advantage that this plan has over spacing-devices attached to the frames themselves. In saying this I do not wish to throw cold water on Mr. Wander's invention, but it is a duty I owe to the younger generation of bee-keepers to inform them *why* such self-spacing arrangements have not proven to be popular.

And here is another one that employs the same principle—or, rather, the spacing-arrangement is in the rabbeted part of the hive:

I have thought of a self-spacing device I will use—a staple made of copper wire, $\frac{1}{8}$ inch thick, and driven into the rabbets of the front and rear end-boards of the hive, and made as shown at the top. The staple will support

the frame, and do the spacing, while keeping the bees from sticking the frames fast to the boards. The wire being $\frac{1}{8}$, the bends will just make the quarter-inch space, and will be better than tins, nails, or tacks, not causing so much moisture as tins, and better for winter.

I had thought of making the support of one piece of $\frac{1}{8}$ wire, as shown in the bottom.

Cuba, Kan., May 22. WM. H. EAGERTY.

This is open to the same objection as the one previously described—namely, the impracticality

bility of shoving a certain portion of the brood-nest from one side or the other of the hive, or of picking up three or four more frames at a time. When the spacers are on the frames, the frames may be picked up, and the fingers grip hold of the outside edges of the outside frames, so there is no danger that the intermediate frame or frames will knock together, because the spacers hold them apart just as when in the hive.

Friend Eagerty's spacers, if, instead of being put in the rabbets, were put in the frames themselves, along the top-bars or end-bars, would make very good spacers—that is, as shown at the top of the engraving. When I first looked it over I thought that was his idea, and I wrote him I thought it was very good; but I have since observed he would make them a part of the hive, and here is where he would make his mistake, as I have already pointed out. Friend Eagerty's plan of staples, especially the second one, is quite old, and has been, I think, illustrated and described in our columns before.—Ed.]

ANOTHER HIVER

"NO PROFIT IN ALL THESE TRAPS TO A HONEY-PRODUCER;" INVENTIONS AND THEIR INVENTORS.

By B. Taylor.

Mr. Root:—On page 402, May 15th, you give a cut of Mr. Alley's latest swarm-catcher. I send you to-day a photo to show that I have been all over this field. The picture was taken four

years ago. The idea is the same as Alley's, except that my device as illustrated has no zinc for the bees to work through. The entrance to

the hive is not interfered with in any way; but when a swarm begins to rush out, the entrance is closed by their force, and the whole swarm is caught with the queen. I tried the zinc and cones, but this is much better. I lay no claim to this idea. I believe this device will work as well as any that can be made; but if any person ever makes one that is practical—that is, profitable to honey-producers—I give notice I will not claim priority, for I have abandoned all hope of making any of these traps profitable. Friend Root, I am almost ashamed to send you this, for it begins to look as though I were going to claim every thing that inventors bring out. The fact is, I have dreamed out and tried a vast range of ideas on apiarian subjects; have tried them until I have come to the conclusion that there is no profit in all these traps to a honey-producer. I believe that the inventors and patentees and makers of these things are the only ones who are likely to get any profit; and the outlook for them is not good enough to tempt me to further effort. I abandon the field to others, and will give any one who makes one of these self-hiving inventions practically useful a handsome sum for the right to use it.

In the articles I am now writing for the *Bee-keepers' Review* I am giving my sincerest convictions in regard to each question discussed. This may look like throwing cold water on inventors; but it is not, for I regard mechanical inventors as the greatest and most useful of the human race. I was talking with a very bright teacher lately, and made the above claim. He disputed, and claimed that a teacher standing before a class of boys and girls, and directing their developing minds, as the grandest human character; but I said, "Mr. K., I fear that, without the aid of mechanical inventors, you and your class would cut a sorry figure—no shirt nor pants, no hat nor shoes, and your scholars in the same fix; no schoolhouse, no books, not even a birch gad to wallop the unruly with; for the moment you break off a sprout and strip it you begin an invention." Reader, stop and reflect in what kind of state the human family would be but for mechanical inventors; and see if you are not forced to agree that they are the greatest and most useful of human beings.

Forestville, Minn.

[B. Taylor is more frank than most of us would be. An inventor, when he gets up something, and has it patented, whether it is practical and valuable or not, is pretty apt to feel that it is the best thing of the kind. In fact, he feels toward it as a fond father does toward a babe. But it is the every-day life that demonstrates the value of these inventions. I know it is true a lot of useless traps are annually poured upon the public; but that public, fortunately, does not very often adopt a thing unless there is use in it.

While your handy bee-hiver, friend T., is not practicable, it represents an idea from which further ideas may develop.

I should hate to discuss that question—which

is the greater benefactor, the schoolteacher or the inventor? It would be like the old discussion in our school-days, that could be argued *ad infinitum*—the beauties of spring versus those of fall.—ED.]

THOSE NON-SWARMING AND NON-STINGING BEES.

By Henry Alley.

Friend Root:—You wish to know about the non-swarming and non-stinging bees. I have this to say of them: In May, 1894, I formed a six-frame nucleus for the purpose of preserving some fine drones to be used in an out-apiary two miles from home. Of course, the colony was queenless, or the drones might have been destroyed. In July the drones had nearly all disappeared from this hive; but in the meantime a queen had been reared, and the young bees were hatching out, and it seemed that they were more than commonly beautiful, and of a leather color. The colony was taken home, more combs added, and in a few weeks it was one of the most powerful hives of bees in my yard. This colony was used to rear cells in an upper story the rest of the season; and before the season closed they had built 250 queen-cells of the finest quality; that is, the queens from these cells were extra fine. You want to know, too, whether the bees are stingless. Well, I am hardly able to reply. I can say that not even one bee of this particular hive has ever used its sting on me; nevertheless, I presume these bees have stings, yet they do not seem to know how to use them. I have opened this hive not less than fifty times, but never knew a bee to take wing or to sting during any operation. Practically this is a strain of non-stinging bees.

Now about the non-swarming part. I have had this strain of bees in my apiary six years, and have never had a swarm of bees from them; and, what is more, I have never heard of any one ever having a swarm from that strain. It strikes me that I can safely claim that they are non-swarmers.

About the colony spoken of, I will say that they are very industrious and active, and wintered finely. They are now the strongest colony in my apiary, and have drones in abundance. I propose to use the drones of this hive for my young queens that will be reared from other fine queens of the same strain now in my apiary. The bees are leather-colored, very industrious, hardy, and gentle. I believe in propagating a race of bees of this kind. Don't you?

Wenham, Mass.

HENRY ALLEY.

[Where any thing is advertised out of the ordinary we generally require an explanation. In our last issue Mr. Alley advertised non-swarming and non-stinging bees. I wrote him, asking him whether he had bees that *could* not sting, or bees that, under ordinary circumstances, *would* not, although having the power to do so if necessary, and the above is his explanation.—ED.]

SHALLOW BROOD-CHAMBERS.

MR. HEDDON REPLIES TO THE EDITORIAL ON P. 409.

Bro. Root:—I am quite surprised at the import of your editorial on page 409. Either you have not yet got the hang of handling my hive (and you must use more than one to ever get it) or I have no knowledge, either practical or theoretical, of handling the old styles, or you never could come to the conclusion that you could compete with a divisible brood-chamber in rapidly determining the true condition of the colonies. I think it would be very difficult to convince those who have tested my hives that any style of single brood-chamber or deep brood-chamber can for a moment compete. You had to open your hive at the top, pull out a division-board, and then pry along one half of your frames with that wire nail before you could determine any thing, hardly, beyond what might be determined from the outside without opening the hive at all. This gave plenty of time for robbers to get into your hive, if any were about, as is usually the case at such times. With the divisible brood-chamber I do not remove the cover at all, but split it in two in the middle, turn up the upper half, and look into both halves at once, or as nearly at once as possible for one not cross-eyed, and put back the little case before a robber could get a taste. My opinion is, that I can handle hives for this purpose somewhere about six or ten to your one.

Yes, you were correct regarding the reason I made the top and bottom bars to my frames only $\frac{3}{4}$ wide, which is just the width that a brood-comb is thick. Now, you find that, between the shallow brood-cases, the bees will put in brace-combs. Certainly they will; but all they put in amounts to more of a bugbear than a real detriment. These brace-combs have some little advantages, and the annoyance is very slight. Those who have learned the great advantages of the use of a divisible brood-chamber look upon these brace-combs as of no moment. I trust that bee-keepers who have not used the hive will remember that, where an opening is made between sets of frames so near the bottom of a brooding-apartment, much fewer brace-combs are built therein.

What you state concerning the space in the middle of the brood-nest retarding the production of brood is, in my opinion, a groundless theory from first to last, wholly in opposition to practical results. It's a part and parcel of the same theory that hives should be square or tall, in order that the brood-nest may be spherical in form. The Bingham eight-frame hive, containing frames holding combs $4\frac{1}{2}$ inches deep and 22 inches long, will show as much brood, and I believe more, than any other style of hive. We have been terribly handicapped in adapting hives to the bee-master, because of false theories regarding adaptability to the bees.

I hardly know why you mention the matter of burr-combs between the top of the brood-chamber and bottom of the surplus-receptacles. I can not see that this is a fit subject, when comparing different hives, for they are *all* subject to the same laws and conditions; whether the brood-chamber is divisible or not makes no difference. At the top of the brood-chamber, where we place our surplus-cases, with *all* hives, where brace-combs are much more liable to be built, and here I always use and for ever advocate the break-joint honey-board. Those who oppose it now will use it later. I assert this from twenty-eight years' experience in bee-keeping, and more than twenty years' use of thick and deep top-bars.

Will you allow me to thank Mr. Richardson for his truthful statement concerning the merits of a divisible brood-chamber, etc., as found in my hive, presented to your readers on page 450? I must confess I can not agree with my friend and collaborer on the point he touches concerning my being derelict in my *duty*, in not better advertising the hive. Surely many bee-keepers, naturally would, and *have* discovered its merits. To a certain extent they have published these merits to the world, and would have done so, and so would I, to a much greater extent, had it not been that we were refused space in the journals. I think I have done pretty well in my book "Success in Bee Culture;" and now in my pamphlet, just issued, I think the job is completed. I can not understand Bro. Richardson's allusion to the matter of others inventing what I did, perhaps, had I not patented my invention, or had I better explained the same. One who can not

fully understand the merits and working of the hive, from the explanations I have made, and immediately after the patent was issued, certainly never could alone have discovered its merits. If I am to blame for not giving it wider advertising, at an earlier date, what shall we say of those who now claim to have discovered and used some of its meritorious features, and yet never published a word to the world concerning them? There is only one thing we can say, and perhaps that had better not be said.

JAMES HEDDON.

Dowagiac, Mich., June 7.

[As I have not yet had reason to change my views as expressed in the editorial under consideration, I will let Mr. Heddon's reply stand on its own merits, without further comment.—ED.]

It is said there are exceptions to all rules. We usually say that a swarm never comes forth unless they have something that they regard as a queen, either young or old. We had the exception this morning that proves the rule. Of course, they went back.

SOME of our apicultural writers are having a little sport over the way in which the editor of the *Cosmopolitan* "put a head" on W. Z. Hutchinson's articles, designating the bee as masculine. Well, we can quite excuse his ignorance in view of the splendid way in which the magazine sets forth W. Z. H.'s beautiful photos.

WE tried a swarm-catcher last week—not the automatic device, but a large cage with a wide mouth to clap over the entrance as the bees rush out. Perhaps we were too late in getting it applied; but it didn't work as we thought it ought to. One swallow doesn't make a summer; but I suspect bees do not feel really satisfied unless they have had a big "pow wow" in the air.

BASSWOODS are blooming beautifully; and the frequent and warm rains that we are now having give promise of an abundant honey flow from that source. Letters go to show that white clover has been largely a failure almost everywhere. If any one has secured a fine crop of white-clover honey, let him hold up his hand. There is going to be a crop of honey in California; but, as Rambler says elsewhere, it will not be such a very large one after all.

It comes to us in a sort of roundabout way that there are some bee-keepers in Canada who are producing sugar honey—that is, a so-called honey produced by feeding sugar to the bees. There is little or none of that thing going on in this country, I believe, and I really hope there never will be. In Canada, some of the prominent bee-keepers are taking vigorous measures to keep such honey out of the market, and I hope they will, for I can not believe that the

average dealer here or in Canada will sell it for just what it is, for then it would not sell at all.

NEW VS. OLD METHODS OF RAISING CELLS.

WE have something over 250 queen-rearing colonies in our home yard. After having tried very faithfully all the later methods, such as artificial cell-cups, raising cells in the upper story of a strong colony having a queen in the lower story separated by a perforated zinc, and all such new methods, we have gone back to the good old ways. The artificial cell-cups are too expensive to make—at least, for us; too expensive to put in royal jelly and larvae; and then, worse than all, we find that too large a percentage of them are rejected. Completing the cells in the upper story of a strong colony with a queen below, works *sometimes*, and sometimes not. The uncertainty of the plan has caused us to abandon it for a good strong colony of *queenless* bees. We save all our cell-cups, and cells from first-class breeders, and put the frame or frames containing them into the queenless colony or colonies on hand for that purpose. There is thus a certainty of results; and where we are selling as many queens as we are now, we always have quite a number of partially completed cells from choice breeders that have been sold out a few days previously. By this plan our cells really cost us nothing, any more than the time of taking out the frames with the cells thereon, and putting them into one or two special queenless colonies, by them to be completed.

WIDE AND NARROW TOP-BARS IN SECTIONAL OR DOUBLE-BROOD-NEST HIVES, AND THEIR EFFECT UPON BROOD-ING-SPACE.

THE double-brood-chamber Danzenbaker hive still seems unfavorable for the rearing of a full amount of brood. We find that a queen will fill clear full one section of the brood-nest before she will go into the other. I feel more convinced than ever that wide top-bars for double brood-nests or sectional brood-nests are not the thing.

A year or so ago the bees all died in our Heddon hive, and combs got wormy. This spring we got out the comb, put in frames of foundation, and hived a swarm on them. The top-bars of these frames are $\frac{3}{4}$ x $\frac{1}{4}$. The queen and bees seem to be working fairly well in both stories at this writing, although I can see there is a *tendency* on the part of the queen to accept one section rather than both at the same time. I can not but feel that the slightest barrier through the center of the brood-nest is somewhat of an obstruction, and a waste of brood-space. The narrower this barrier or top-bar, the less the obstruction. But wide top-bars, or wide and deep either, for that matter, do not seem to hinder the *bees*. In fact, they may be considered an advantage in that they keep the

queen below, and allow the bees to put surplus where we want it.

BEES AND FRUIT.

AN interesting paper on raising fruit was read recently before the Ravenna Grange by Mr. Smith Sanford. After stating the conditions necessary for that business, and the enemies and drawbacks to contend with, the matter of the influence of bees on fruit came up. Mr. Sapp gave the following strong testimonial as to the value of bees to the fruit-grower:

Mr. Sapp referred to the part that bees take in successful orcharding. He referred to orchards which had produced abundant crops of fruit when a number of colonies of bees had been kept near the orchards, that had partially or completely failed after the removal of the bees.

As the above comes from outside of our own ranks, it is of special interest. We are indebted to the *Ohio Farmer* for the clipping.

THE APICULTURAL EXPERIMENTS, AS REPORTED IN THE REVIEW.

I AM always glad to read the articles in the *Review*, by R. L. Taylor, detailing his experiments at the apicultural station, providing I can study out the conclusion. But several times I have found myself almost unable to gather the lessons taught by the tables. I suppose it is my own thick-headedness, but I have heard others speak of it several times. If our friend R. L. T. would help us to translate them a little more it would add greatly to the value of the report. I was about giving an editorial summary of the one in the *Review* of June 10. I may be thick-headed; but for the life of me I could not boil it down. I kept still, however, and said to my co-worker, our proof-reader and stenographer, in my usual tone, "I wish you would make an editorial summary of this." I have sometimes asked him to do this before, when I have been pressed for time. The next day I came around and said, "Well, have you got that summary?"

"No," said he, "that is a sticker."

"Have you read it?" said I.

"Yes, especially the reading-matter; and while there are many interesting and valuable facts all through the article, I can not bring them all to a focus so as to state the result of the problem as a whole."

I know my friend Mr. Taylor will not take it unkindly when I say I am not fault-finding; but I make it as a criticism, hoping that it will enable some of us to understand the tables a little better. He sometimes gives us a summary, or the gist of the matter in a nutshell, and thus unquestionably throws much light on the tables, making their meaning more intelligible. Perhaps I ought to be able to do this; but surely Mr. Taylor can interpret his own figures more correctly.

I am willing to acknowledge that I have my fair share of thick-headedness; but some of the brightest bee-keepers I know of acknowledge that they have been greatly indebted to GLEANINGS for the editorial summaries of the Michigan apicultural reports, as they were not able to understand the original report in the *Review*. I should like to give the names of some of these bee-keepers; but for fear they would not like the mild insinuation that they are thick-headed, like myself, I forbear.

The point is right here: There are very few readers who will take the time to study out a set of figures, or read a thing through several times to get its meaning. If they do not catch the meaning at first glance they will simply skip it.

FOUL BROOD; HOW TO GET RID OF IT AMONG NEIGHBORS; THE POLICY AT THE HOME OF THE HONEY-BEES.

WE recently got track of a bad case of foul brood in our own county. Some time ago I took a bicycle-trip down to investigate. Sure enough, it was a rotten case, and needed complete extermination. As it was only about seven miles from us, I offered to furnish the party foundation, frames, and hives, if need be, all new and complete, free of charge, on condition that he would burn frames, hive, and all, but save the bees if he liked, by driving them on to frames of clean foundation. We feel that we can not afford to have that dread disease within even seven miles of us.

I think it greatly behooves all intelligent and progressive bee-keepers, when they know of cases of foul brood, to offer, if need be, the owner of the infested stock their services, and furnish them foundation, frames, and a new hive. Our apiary is perfectly healthy, and we have little to fear of the disease making any serious inroads on us again, because we feel that we are able to nip it in the bud. But notwithstanding this, we take every precaution, and therefore sell nothing but queens by mail. The business of selling nuclei or bees by the pound was discontinued over a year ago. The mere fact that foul brood broke out in our own apiary some years ago, and reappeared in another yard some five miles south of us two years ago, and again within a few days past in an apiary seven miles north of us, leads us to believe our policy is wise. But we feel perfect safety in selling queens, because we never knew of a case where a queen carried foul brood from one colony to another. A very few such cases have been reported; but there are so many other ways in which it could have been carried, I have been inclined to doubt them all. In fact, as our older readers have known, when we had foul brood we carried queens from diseased colonies and introduced them into perfectly healthy ones. The experiment was repeated a good many times, but foul brood never appeared where the queen was put.

FLORIDA TRAVELS.

There are a good many surprises in Florida. You get a little homesick, and every thing looks dull and dreary; the towns look dilapidated and run down, and the landscape looks like a barren desert. But all of a sudden you come across some example of luxuriance and productiveness, like the grape-fruit tree near friend Stacey's house. By the way, I want to say a word more in regard to this grape-fruit tree. In mentioning the matter, several friends assured me that, especially in Florida, the trees around most houses grow with remarkable vigor, and no theory has yet seemed to explain the matter fully. Some suggest that the shade of the house conserves fertility; others, that the waste and trash from the average family makes the ground rich; and one friend, whom I shall mention further on, goes so far as to gather all the trees, trash, rubbish, and almost every thing he can lay his hands on, to mulch the ground around his orange-trees. He claims that mulching and shading are elements of fertility.

Well, there are other surprises that meet you in Florida, especially after you have begun to think the little towns and villages do not amount to very much—and some of the villages and railroad stations are, in fact, not much more than a store and postoffice; but now and then you see something that upsets the idea that there is nothing "going on" in Florida. A startling surprise awaited me when I set foot in the city of Tampa. The total population of the place, I am told, is about 18,000. There are beautiful paved streets, fine buildings, a street-car line that runs to Ybor City (pronounced Eebor); and, most astonishing of all, is to find away out there in the wilderness and sandy wastes the Tampa Bay Hotel. The hotel—well, look at the picture on the opposite page, and then believe me when I tell you it lacks only a few feet of being a quarter of a mile long. These great hotels in Florida are, in some respects, a sort of manufactory. They manufacture right on the premises, by means of steam and electricity, and skilled artisans, every thing to make a traveler comfortable. The nicest water is hunted up, even if they have to go many miles for it, and a great engine sends it where it is wanted. The same engine furnishes power for driving fans, lifting elevators, and helping about the kitchen wherever power will help. The kitchen is a sort of manufactory where the best eatables are made in quantities sufficient to supply a considerable town. I have forgotten how many guests this hotel accommodates, but it is something like a thousand; and at the time I was there I was told the rooms were all occupied. The picture gives you some idea of the grounds and surroundings, and of the beautiful drives and walks, made of Florida shells, which I have already described; also the trees and tropical plants and shrubbery. In the foreground you have a view of a beautiful iron bridge that leads to the hotel. Various greenhouses and conservatories furnish every thing to make all the rare and tropical exotic plants feel at home that are to be found anywhere on the face of the earth. The architecture is, I believe, what is called Moorish. The building is all of brick, and this was a great relief to me, because, you remember, I had been somewhat disgusted with the make-believe imitations of stone, made out of sheet-iron and paint. There is not any

whitewash to drop off nor show through on the Tampa Bay Hotel. Some of you may be inquisitive as to what should make such a thriving live city as Tampa, away down in that part of Florida. Well, I was just thinking I should much rather say nothing about the principal business of the city and vicinity; for, to tell the truth, Tampa is said to be almost headquarters for the whole world in the manufacture of cigars. I did not visit any of these factories, although I was invited to do so. When I am an invited guest, and my friends take pains to show me around, I usually feel bound to be pleased and to look happy, learning about things that I never knew of before; but if I should look pleased and happy while being shown over a great manufactory that confines its operations to cigars and tobacco, I am afraid I should not sleep well when it came night time.

Out a little beyond Ybor City I found some beautiful gardens carried on by a system of irrigation, quite extensive, and fully up to the times. Ybor is the name of the most wealthy man in Tampa, and he was greatly instrumental in building it up. He is a Spaniard, and has extensive tobacco-plantations in the island of Cuba. For some reason, unknown to me, the locality of Tampa City seems to be better for his line of business than Cuba.

While I was looking over the big hotel I was greatly surprised to see a strange race of people, unlike any thing I had ever seen before. As the train pulled up, a lot of nicely dressed pages, or waiters, came to take charge of the trainload of visitors. These waiters were mostly young boys, say in their teens. Their style of dress was foreign, perhaps somewhat after the oriental style; and some of these young fellows were sufficiently good-looking (notwithstanding their swarthy skin) to make many of the girls envious. They spoke some foreign tongue that I took to be Spanish. Let me say to their credit I found them to be exceedingly courteous and obliging whenever I asked any questions of any sort.

At Lakeland I found W. C. Green, who had given me a very warm invitation to come and see him. Friend Green is a genius, and an odd genius. His hives are arranged in groups in his dooryard. Some of the hives are very tastily located in an ornamental summer-house. Almost as soon as I came into the dooryard he commenced to show me his beautifully marked Italians. He began opening one of his hives, with so little ceremony that I dodged back; and he laughed at me some to think that A. I. Root should be afraid of bees. I told him I was not a bit afraid to open any hive in his yard, and that without smoke or veil; but if he was going to yank off covers in the way he had just commenced, I thought I would keep at a safe distance. He said his bees were properly trained, and would not sting, even if one did burst into their domains without so much as even a gentle rap to let them know you are coming. Well, the bees came out and filled the air. They buzzed around his ears, and I felt almost sure he would get stung most severely; but he did not get a sting. The next day, however, he attempted to do the same thing with a log gum that we found away out in the woods in a neighbor's yard, and both he and the owner got stung until they were quite ready to beat a retreat. Friend G. has a pretty home, and quite a family of boys and girls.

In the afternoon we started out on an exploring expedition. Mr. H. S. Galloway has nine acres of strawberries. His variety, which he calls the Newnan, is a perfect-blossoming kind. I found his strawberry-ranch on ground so low and wet that water stood in the furrows over a

HOTEL AT TAMPA BAY, FLORIDA.

great part of the patch. I commenced at once recommending him to put in tiles, and get rid of all the water. Friend Green told me I might know all about strawberry-raising in Ohio, but that I did not understand it in Florida. Of course, the frost had played mischief with the early crop. Strawberries are planted here in double rows, about three feet apart. These double rows have the plants a foot from each other in every direction, and they are permitted to bear but one crop. After they are done fruiting they are allowed to put out runners enough to make a new plantation in the fall. The fall-set plants bear the crop in February and March. We got over on a protected side of the woods where the tall timber had kept off the frost; and I was delighted to find here and there ripe strawberries in the month of February. Somebody has said (I do not know who) that the strawberries of Florida lack the fine flavor of those grown away up north, where we have zero weather, and snow as high as the fences; but when I got a taste of a fairly ripened berry I declared at once it was the most delicious strawberry or fruit of any kind I ever tasted in my life. After I had sampled quite a number it occurred to me they might be more valuable than I knew; so I remarked:

"By the way, friend Galloway, you say you have already marketed a few. What price do you get for them at this season of the year, if I may inquire?"

"Oh! I have an offer of \$1.50 a quart for some I expect to get off perhaps to-morrow."

"Dollar and a half a quart!" repeated I, as I took a great luscious berry away from my mouth, where it was *almost* safely lodged. "Now, look here, my good friend," I continued, "perhaps I owe you an apology for helping myself so freely. I do not think I want very many, even if they are so delicious, if *that* is what you are getting for them."

"Oh! help yourself—help yourself, Mr. Root. When I told you the price I am offered I did not think a word about those you have been eating. And, by the way, this price is a little extra on account of the freezes. I think it is about the best figure I was ever offered."

A few weeks afterward, while I was in Jacksonville, I found out how they managed to be able to pay such a price. Little cards were up on the sidewalk, advertising ice-cream with real strawberries; and the strawberries were right close to the notice, to let people see they were *genuine*. The dishes of cream were furnished at the usual price; but they managed to make one quart of strawberries make a *good many* dishes. When I asked friend Galloway about manuring his ground he replied that he had settled down on Bowker's strawberry fertilizer, applied to his ground at the rate of 500 lbs. per acre.

The next neighbor we called on was a bee-keeper; and as he is right on the shores of one of the beautiful lakes, he does quite a little in the way of catching fish. Oh! I did not tell you that Lakeland is *surrounded* by beautiful lakes. Friend Cochran (where we were visiting) had a contract to supply six dozen speckled perch at a certain hour in the afternoon. I suggested to friend Green that it was not fair to hinder a man when he was trying to fill an order, and that he and I should get into the boat and help him by catching fish too. Well, I did help. I caught *two* beautiful perch while friend Cochran caught *twenty-six*. I had a hook and line and pole just like his own; and I dropped my hook into the water just as he did, and yet he was catching fish all the time and I was not. Is there a trade or skill in just dropping a baited hook into the water and then watching for the cork to bob up and down?

Indeed there is. The old veteran fisherman could tell at a glance about where the perch would be likely to be hidden near certain water-plants. Then he knew how to drop the line without making a great splatter and racket. Furthermore, he kept his line moving, just about enough to coax the fish without frightening them away. Now, friend C. is an expert in his own line of work; and I am sure friend Green can testify with me that his good wife is *also* an expert in her line of work; and that line consisted in getting us a grand good dinner, mainly from the fish we had just caught in the lake. By the way, what do you suppose these speckled perch that are caught by the hundred, sometimes, in a single afternoon, bring in the markets down in Florida? Why, only *three cents* each. They do not sell fish by the pound down there. They are like eggs—so much a dozen.

Now I shall catch it again for what I am going to tell; that is, some of the friends who think I am inducing people to move down to Florida just to be disappointed, may be will grumble some more. The story is this: Not very far from friend Galloway's strawberry-ranch a piece of ground was lately sold for \$1.25 per acre. Friend Green, with whom I was visiting, was the lucky purchaser. It was right adjoining the railroad, besides, about seven or eight miles from Lakeland, and a steam-sawmill was located right there, cutting up lumber at the time of the purchase. After friend Green had bought the tract of land, he took the proprietor of the sawmill over on it and sold trees enough from the tract to more than pay the purchase money. The mill-man paid so much apiece for the trees just where they stood in the woods, so friend Green had no expense whatever to stand in the matter. A nice large straight pine-tree brought—how much do you suppose? Only 20 cts.; and some of them that were not quite so nice sold for two for a quarter. Well, 7 trees on an acre, at 20 cts. apiece, paid for the land. Then the railroad company offered to make a flag-station right there by the sawmill if friend Green would put up a little building, and the building was already up. I asked friend Galloway before I left what he considered his best strawberry ground worth per acre. He said it was not for sale, but finally decided he would not want to part with it for less than \$100 an acre; and the land that costs only \$1.25 is hardly a mile away; and I thought, from the looks of it, it might be exactly as good. You may ask why such chances are left "lying around loose." Well, one reason is that people are too lazy to go to work and build up a business as friend Galloway has. Another thing, there are a great many who do not seem to have the ability to make the wilderness blossom as the rose. Even if they were to undertake it they would have bad luck here and there, and perhaps everywhere. I should enjoy going into those Florida wilds and building up a home; and I am just conceited enough to think I could make things grow as those strawberries do, and as that grape-fruit tree does I was telling you about.

It was Saturday afternoon. I was getting so much behind with my appointments that I was obliged to push on. I had half an hour to wait for a train. I had read newspapers, and read over the bills stuck up over the walls of the depot, and felt a longing for something that would help me study my Sunday-school lesson for the morrow. I went over to the drugstore and asked them if they had any periodical to sell that would answer my purpose. Although they kept a sort of news depot, the proprietor told me they never had any calls for any thing in that line. When I looked disappointed he

said he had a copy of the *Sunday-school Times* that he used himself that I might have if it would be an accommodation. I had hardly had a glimpse of my old home paper during the whole time I was in Florida; and I tell you I just felt happy as I sat down and went over the pages so familiar to my eye. It was meeting an old friend away off in the desert wilds, and it cured me of being homesick, straightway.

OUR HOMES.

And God saw that the wickedness of man was great in the earth, and that every imagination of the thoughts of his heart was only evil continually. —GEN. 6:5.

On the evening of Wednesday, June 5, it was my good fortune to be present at the address of Anthony Comstock, given at the State Sunday-school Convention in Cleveland. Probably every reader of GLEANINGS knows something of the work of Anthony Comstock. For a period of almost 25 years his name has been almost a household word when the subject of social purity and the morals of our children have been under discussion. Previous to Mr. Comstock's vigorous prosecution, vile and indecent books were passed about, and swapped back and forth, even by schoolboys; but for the past fifteen or twenty years I have hardly known of such a thing, unless it was to make mention of the apprehension and arrest of the man or boy who started it; and they almost always of late years get brought to justice by the time they have got well started. Now for the discourse:

The main part of the speaker's talk centered about the imagination. He said that even a child began, and that, too, at a very early age, to people its thoughts with images. In fact, he put it in something this way: There is in the heart of every human being a sort of picture-gallery—a little room, we might call it, the walls of which are adorned with pictures of some kind. If the parents, the teachers, the pastor, the Sunday-school teachers, and others, do not see to it that the apartment within the little heart of every child is hung with good, wholesome, and *pure* pictures, the prince of darkness will surely see to it that these little walls are adorned with pictures of some kind, and that very quickly; and these pictures, too, will be of a very impure and low description; and it is the character of these pictures that fixes the thoughts, the actions, and the life, of the coming human being. If the imagination is allowed to dwell on fancies of a vile character, the future life of the person soon becomes *vile*. The subject of the discourse, I believe, was, "Our Children and their Environments." My good friend, if you have no children of your own, you have brothers and sisters, or relatives—children whom you wish to grow up good and pure and useful. What are their environments? What are the pictures they see? Are they permitted to select their own pictures and their own reading, without any parent or guardian to direct them? I have often told you of the sad stories that I have heard during my visits at our county jail. A boy borrowed a highwayman's book. I believe it was the history of Jesse James. I do not know whether the book was put out with the intention of having it prove a warning to our boys or not; I only know that it fired this boy's imagination with a desire to be a Jesse James himself. He stole a horse, and I found him in jail; and he confessed to me it was a very hard matter indeed for him to get Jesse James out of his

mind and choose the straight and narrow path instead of the broad way that leads to destruction. Yes, after I had patiently and kindly talked the whole matter over with him, from beginning to end, and when he assented to reason and common sense, yet there was a longing for unlawful adventure that he could hardly root out of his mind and his *imagination*. Some of my readers may think this very strange; but I am inclined to think there are others (perhaps a large portion) who will, in their own hearts, recognize that that boy was not, after all, so very much worse than some older people.

We all know more or less about the imagination, and how much it has to do with our acts in life. I was almost startled to hear Mr. Comstock quote text after text from God's holy word, indicating how much the imagination has to do with these lives we are living. Let us look at one of the chosen texts. For instance, away back more than 5000 years ago, "every imagination of the thoughts of man's heart was only evil, and evil continually." Again, in that same book of Genesis, two chapters further on, we read: "For the imagination of man's heart is evil from his youth." Let us now go on to Deuteronomy, 31:21: "For I know their imagination which they go about, even now, before I have brought them into the land which I swear." Again, I. Chronicles, 28:9: "For the Lord searcheth all hearts, and understandeth all the *imaginings* of the thoughts." Again, in the next chapter, 18th verse, Solomon says in his prayer: "O Lord God of Abraham, Isaac, and of Israel, our fathers, keep this for ever in the *imagination* of the thoughts of the heart of thy people, and prepare their heart unto thee." In the latter you will notice the imagination may be a power for good instead of an element for evil. Again, Proverbs 6:18: "A heart that deviseth wicked *imaginings*; feet that be swift in running to mischief." Again, Jeremiah 3:17: "Neither shall they walk any more after the imagination of their evil heart." Again, Jeremiah 7:24: "They walked in the *imagination* of their evil heart, and went backward and not forward." Again, Jeremiah 18:12: "We will walk after our own devices, and we will every one do the *imagination* of his evil heart." The prophet had been pleading with them in regard to their wicked ways, and he tells how they reply. Perhaps they replied by actions rather than by words. They say, "We will walk after our own devices, and we will every one do the *imagination* of his evil heart." Surely Anthony Comstock has abundant reason, and reason coming from Bible quotations, to support him in his position, that the sin of mankind has its root in the imagination. He said it was often stated that intoxicating liquors are the crowning sin of the present day; but while he was fully aware of all the devastation and ruin that come from intemperance, it was his honest opinion that impurity in thought, and the sin of holding fast to evil *imaginings*, is a greater sin than all the intoxicants together that curse our land.* His talk took a wonderful hold upon me, because, perhaps, I have been more than usually imaginative all my life. When I was a child I would sit still and laugh at my day dreams, or build air-castles, as it might be termed. I have been laughed at because I myself laughed at my fancies—that is, I often laughed aloud at some occurrence that was *purely* imaginary. Now, that is not so sad a thing as it is to get into a fashion of allowing your *peace of mind* to be disturbed by simple fancy. It is not a week

*The *imagination* of an intemperate man is often more dangerous than any *outside* influences.

since I found myself getting into a troubled state of mind because of something that I *imagined* might be. I put it away again and again. I went to work at something that would take my thoughts to another subject. This answered for a while, but back it came again. I prayed that God would deliver me from the hideous thing; but it required constant prayer until the time came when I could ascertain whether my fancies were real, or whether it was *only fancy*. The event proved that it was *only fancy*. In this case I had been borrowing trouble—borrowing indeed. Mr. Comstock told us that, when vile pictures have once been placed in this little picture-gallery of the soul, it is not always an easy matter to get the picture down and put some other one in its place. The old one has a fashion of showing *through*; and if you look intently where it used to hang, the lineaments of the old picture have a fashion of coming out stronger and stronger, like developing a photograph. You can almost *resurrect* an old and dead picture if you look where it used to be, and *long* for its presence again. Nowadays we have a way of making pictures by simply pressing a button. Evil imaginations are ahead of the Kodak, and you do not have to “press the button” at all. You simply *think* the evil thought, and there is the picture, more vivid and real—yes, and a thousand times more pernicious—than the real thing itself. I am not quoting Comstock just now. I am thinking of some of my own experiences. Imagination not only makes new pictures, but clothes vice so as to make it look like virtue. Imagination, with Satan in the background, will make you think your worst enemy on earth is your best friend. Imagination, with Satan out of sight in the background, will take a very commonplace person, and he will make that person look to your distorted vision like a seraph. Your *imagination*, if not held by the reins of reason, may induce you to bow down in the dust, and *worship* a piece of humanity not only commonplace, but vile and deceitful. If you have not had any experience in this line you *may* have before you die; and remember your old friend A. I. Root warned you. You need not delude yourself by saying you are too *old*, and have too many gray hairs for any such youthful folly. Satan laughs at gray hairs, and well he may; for some of his veriest *dupes* are found among those who are surely “*old enough*” to know better.

It is a little strange that men right here in America, in this nineteenth century, should lend themselves to Satan's work along in the line that Anthony Comstock has been fighting. This form of iniquity seems to start up here and there, and often where least expected. No matter how many are caught and sent to the penitentiary for disseminating vile literature, the thing has to be *continually* fought. Mr. Comstock has caused the arrest of nearly 2000 different persons within the 22 years that he has been at work. The mails are now so carefully guarded that it is dangerous business for these people to undertake to mail any of their hellish trash. I have been wondering whether it is possible that the *only* incentive to this traffic should be the *money* they get from it. Years ago, pernicious books would get into the schools. They would be passed about from one boy to another, and sometimes the vile thing would go almost through the school before it was stopped. Fathers and mothers used to be (at least some of them) stupid and indifferent about these things, compared to what they are now. Not long ago a man in one of the streets of New York was handing some packages to children as they were on their way home from school. A little girl received one. She read on

the outside, “Don't open this until you are off alone by yourself.” But the Devil made a blunder that time. Keen as he usually is, he got hold of a little girl who had the wrong kind of bringing up for his schemes. She marched straight home to her mother and held up the package. “Mamma, a man gave this to me. What does it mean?” I can imagine how mamma's eyes blazed as she opened the packet enough to divine its meaning. She replied, “Go with me this minute and help me to hunt up that man. He is a thief and a robber. He is worse than a mad dog let loose.” The child had faith in her mother, and the two started out. They found him still at his work. A policeman arrested him, Anthony Comstock was sent for, and the man is now serving out a sentence of *eight years* in the penitentiary. May God be praised that we have little girls who will go straight to their mothers with every thing of this sort. May he be praised again for such mothers, and for Anthony Comstock. A few years ago it was customary for agents of this kind to collect the names and addresses of schoolchildren; but the mails are now handled with such keen scrutiny that they have about given it up. They confine their operations mostly to such boys as they can find in the saloons. Intemperance and impurity go hand in hand, arm in arm; and let me say to the few good people who defend tobacco, that Anthony Comstock gained the fierce hatred of almost the entire cigar-trade. Do you know why? It was because he meddled with their business. These dens of infamy had found out that a vile picture could be put into a box of cigars, and neither the man who smoked the cigars nor the man who sold them would “squeal.” Why, go into any place where they sell cigars, and look at the pictures on the boxes. Do you want your boy to see such pictures? Do you want that little picture-gallery within his pure unsullied heart embellished with such things as these? Do you want his undeveloped childish imagination to begin *feeding* on things of this sort? Most fathers look back and remember at least times in their lives when they felt the baneful, blasting, withering effects of evil imaginations in this direction.*

Last, but not least, every Christian knows that this sort of sin is the worst foe to spirituality. A boy may be on the eve of giving his heart to Christ—nay, he may be studying for the ministry; and one single vile picture, or one indecent book, may kill out all thoughts of nobler and higher things. Satan is saying, even to-day, “All these things will I give thee if thou wilt fall down and worship me.” And, O dear friends! the saddest part of it all is, that many of our promising young men have accepted the bargain. They have, in consideration of what Satan has pictured to their imagination, given up all, and sold their souls to *him*. Yes, *sold* is the word—sold, body and soul; sold to everlasting death and ruin.

There is a hopeful thing about all this, however. The affairs of our State and nation are surely getting, at least to a certain extent, into

*Seed of this sort, sown in the heart at a certain age, takes root and grows with amazing rapidity. “Whatsoever a man soweth, that shall he also reap.” And this is *terribly* true of vile things that once get a hold of the youthful imagination. The crop comes, too, oftentimes, in an incredibly short space of time. Do you know where the reaping is done? In the county infirmary and in the insane-asylum. Go visit institutions of that kind; make inquiries in regard to the inmates; and when you get down to the facts you will find that a great majority of the occupants have come there through feeding the *imagination*, at an early age, on this very trash that Anthony Comstock is waging such determined warfare against.

the hands of the *mothers*. The mothers do not use tobacco; and may God be praised for this one comforting thought; and still more comforting—yes, it ought to be a thousand times more comforting, when we reflect that the *mothers* are not and *never can be* in favor of vile pictures and impurity. Every mother knows—in fact, it is stamped on every fiber of her being, that not only the safety of her boys and girls, the safety of the home,* the safety of humanity, the safety of this whole world, of intellect and righteousness, depends almost entirely upon purity in thought and life. Impurity and sensuality are the enemies of the home; they are the enemies of every thing pure and holy. Sometimes it has seemed to me as if there were only one Anthony Comstock in our nation, and that, when he dies, Satan would take courage, prick up his ears, and open up business again. God forbid! Every *father* should be an Anthony Comstock on the home guard. Every mother is already, if she only knew it. May be she needs waking up a little, and needs to be reminded that she as a mother is one of the officers. Yes, God has chosen her, and God calls upon her to make herself heard and known. May God help us; and may he help *me* to keep constantly before my eyes and before my imagination that grand little text that should find a prominent place in that little picture-gallery (the imagination) in these hearts of ours. Give it lots of room, and fix your eyes upon it often:

BLESSED ARE THE PURE IN HEART, FOR
THEY SHALL SEE GOD.

MULCHING AND MANURING STRAWBERRIES AT ONE AND THE SAME TIME.

We have about an acre of strawberries that are growing their third crop. We ordinarily let them bear only two years; but we kept working and manuring this patch in order to get plants, and this season we proposed to plow it under just as soon as the last berries were picked. Only part of it was mulched during the winter. We do but little mulching, because we want to work the ground in the spring so as to get nice plants for shipping. But just before

* A real true home can not well exist without a father and a mother; and impurity would set to work the very first thing to break up a home. A few days ago I took a hasty glance into a popular magazine. Mind, I say "popular;" but in all its long years of record it has never been prominent for its godliness. This magazine was speaking about unhappy marriages, and divorces, and a suggestion was casually thrown out that the home should consist of only the mother and the children, and that grown-up men should be at liberty to go where they please, and do as they please, providing they, *collectively*, support the women and children. In that case we should all of us have mothers but not any fathers. Oh, yes! we should have fathers, after a fashion; but although the boys and girls might know their mothers, each and all, quite well, they might or might not know which father was *their* father. The suggestion has haunted me like a nightmare. It certainly came from the prince of darkness, and from the lowest depths of the bottomless pit. The man who has not manliness enough about him to stand up before the world and acknowledge himself the *father* of his own children (each and every one), and the lawful husband of the *mother* of those children, had better spend his life in the penitentiary, for he does not deserve any better place.

picking-time we found we should *have* to mulch with something. Muddy and gritty strawberries are behind the times. Every strawberry-grower ought to be ashamed of offering dirty berries. On the fairground, near our place, there are some horse-stables where they make a great quantity of loose straw manure. It is so much straw and so little manure that I pay only from 50 to 75 cts. a load, and this for a load that we bring on our hay-rack. Well, I thought I would use this for mulching to keep the berries off the ground. You know how the frost cut them off, and just about spoiled the Jessies with some others, and then the hot drouth diminished and dried up what few berries were left. Well, we had pretty much given up getting any strawberries worth mentioning; but a pretty good rain came on the evening of the 19th, and lasted during the forenoon of the next day; and almost as soon as the rain was over I was happily surprised to see not only the bright new foliage, but stems of berries sticking up here and there that had just about doubled in size during the rain; that is, they were twice the size they would have been had it not been for the rain and manure. Well, now, that acre of strawberries is bearing considerable nice fruit, and making plants at a tremendous rate, under the influence of the straw mulching and the manure. One objection to stable-manure has been, you know, weed seeds; but if we are going to plow the patch under so soon, who cares for the weeds? The more they come, the better. I propose now to let the whole thing be until both weeds and plants get at their best, then we will take out the best of the plants, with a lump of dirt adhering, and make a new plantation right beside the old one. By this time the weeds will be up so as to be worth something to plow under; and thus we shall have a splendid piece of ground for buckwheat and crimson clover, as mentioned in the last issue, or for any other late crop.

A VISIT AMONG THE STRAWBERRY-GROWERS.

Saturday afternoon, June 15, I started out to see what my neighbors were doing in the height of the berry season. About ten miles northeast of Medina I found the Lawnsdale fruit-farm, on ground high enough so they were affected by the frost but little compared with our own locality. Friend Williams, the proprietor, raises strawberries, raspberries, blackberries, gooseberries, and currants, with potatoes for filling in and to make a sort of rotation of crops. He has about 30 acres of land, and it was really a refreshing sight to behold such a berry-farm right in the midst of a locality where every thing else is devoted to regular farming and stock-raising on a heavy clay soil.

On a northern slope near the road I found about an acre of strawberries that was worthy of a picture; but I did not have the Kodak along that time. The berry-plants are in rows, apparently about four feet apart, like our own. They were so well mulched with straw in the fall that not a berry could find a grain of dirt or soil to rest on. Friend W. hit it exactly in being slow to remove the mulching. He kept the plants back all he could without injury, and then gradually made openings in the straw to let the plants come up through when they were ready to start. By the way, I have never found anybody yet who would remove the mulching with sufficient care to suit me. They would go and claw the straw all away and throw it in the paths. Now, the straw should not be moved a particle. Let the berries go up through it, leaving the straw where it is; then you will have a perfect mat to keep down weeds and to keep the fruit out of the dirt. It also

serves to keep the berries back so as to avoid a late frost. Only two kinds were on this patch—Crescent and Downing—three rows of one and then three rows of the other, and so on. Varieties that succeed splendidly here in Medina do not prove to be the best there, just ten miles away, and therefore I feel sure it behooves every strawberry-grower to test, say, one row of each of the best kinds prominently before the public; then make a selection of what suits your locality, and stick to your selection. I do not believe any grower wants very many kinds for fruit alone in his locality. It may pay him to have a few Michel's Early, and, say, a few late ones like the Gandy; or if other extra late ones or extra early ones do better, take them instead. Friend W. does almost all the work on his 30 acres with the help of his wife and two children. It keeps them pretty busy, especially during the berry time; but, if I am right, the *happy* families are the *busy* families. I shall long remember the hour I spent in and around that pleasant little home. And, oh! by the way, I picked up

A HORSE-STORY

at that home that I am sure will interest you. Friend W. is about two miles from the town of Brunswick. His girl attends school there, and comes home nights. Now, this will do very well in good weather; but how about bad weather? I will tell you. They have a sagacious, gentle horse that takes the young lady to school every morning, and comes home *himself*. About the time for school to be out he goes back for his young mistress. As there is not any driver he sometimes takes things easy in going the two miles, and does not reach his destination till after school is out. At such times the young lady comes to meet him on foot along the sidewalks that go a piece out of town. He has learned that, when he meets her, he must turn around and go back again; so he watches all the little girls of about her size as they come out of the school and come down his way, turning his head and pricking up his ears while he scrutinizes each miss to see whether she is the one he "belongs to." Sometimes he seems somewhat undecided, and stops in the road to take a better look. When he is satisfied the one in question is not his "best girl" then he goes on for the next, and so on. This brings in an interesting point just here: How far can a horse see, and see plainly enough to distinguish one person from another? I suggested that meddlesome people might tie the horse up, thinking it was astray; and they very soon found that a card would have to be hung on to the harness, to the effect, "You let me alone, I know where I am going, and I am all O. K." After this, especially as the people round about have "caught on," he made his daily trips without hindrance.

THE BARBER BERRY-FARM.

This is about two miles directly north of Brunswick. It is near what they call Stone Hill. As I pushed my wheel up the neat gravelled path under the trees, a pleasant-faced woman met me with smiles, telling me her husband was just starting off, but that I could stop him if it were attended to at once. Friend Barber has been in the fruit-business from childhood up, and he has perhaps 50 acres on a gravelly stony hill, devoted entirely to fruits. This hill is a very high one. The slope toward the west must be down a hundred feet or more; and the consequence is, he has his trees and berries loaded with fruit—grapes, plums, cherries, peaches, etc. It was a real pleasure to me to find I was able to name not only all his strawberries, but his raspberries, currants, and some of the blackberries. After experimenting

some he has decided to plant the Victoria currant almost entirely, and nothing else. For raspberries he has the Cuthbert for red, and Gregg for black; some Shaffer's Colossal, and some Marlboro for early. He not only uses the hill, but, like myself, he has a creek-bottom strawberry-patch which is nice to start plants; and when the frost holds off it gives quite a lot of fruit. Various springs in the hillside would probably fill a reservoir sufficient to irrigate his lower grounds, and he is just now planning to have this done.

REDUCING THE EXPENSE OF PICKING.

Friend Williams gave a valuable suggestion right here. Both he and Mr. Barber had their berries picked at the rate of 5 cts. for a four-quart basket. Now, it costs more than this to get our berries picked; but we pick them every other day. Friend W., by using Crescents and Cumberlands, can wait three or even four days, as the berries are firm enough to stand handling, even if some of them are a little overripe. You see, the pickers can work cheaper where the berries are very plentiful. Heavy mulching, with his peculiar soil, perhaps helps to raise berries that will stand this length of time between the pickings.

Before I was half through looking at and sampling the Haverlands, Cumberlands, Jessies, etc., the sun was setting, and I was ten miles from home Saturday night. Oh what a nice thing is a wheel! We were back in the fields about half a mile from the road, and the half-mile was up a long steep hill. I suggested that I could cross the fields and strike the road in the valley, as that route would be much less hilly for me for my trip home. Now comes in the advantage of a light wheel. I could hang it over my shoulder, climb fences, or get through bushes, without much hindrance. It made me puff some until I struck the highway, and then what a delight it was to spin along a road almost level! To really enjoy wheeling to its fullest extent you should walk occasionally until you are tired of walking; then the wheel comes in and gives you that delicious rest. A boy in his teens came down from a pretty house by the way, and mounted *his* wheel. He did not see me; but I thought I would, just for the fun of it, run past him and show him what an 18-lb. Rambler could do. But I did not show him the Rambler at all. Do you know why? Why, he kept ahead of me in spite of any thing I could do, and in a little time he was away off in the distance, clear out of sight, even if his wheel did weigh more than twice as much as mine did. Never mind. I always feel glad when somebody gets ahead of me, even if I had planned otherwise—at least, I hope I do; and I am certainly happy in seeing the boys and girls put distance to naught, even outdistancing myself in it. There seems to be something especially fascinating about wheeling during twilight; and after visiting California and Florida, and experiencing almost sudden darkness as the sun goes down, I enjoy our Ohio twilights more than I ever did before.

My road was a little back from the great highway of travel; but there seemed to be an unusual number of pretty homes. At different times I had visited some of the places, talked with some of the young farmers about tiling their low lands, and utilizing the springs for irrigation, etc., so that the improvements that met my view added largely to my enjoyment. As I neared home I passed through the locality of the Abbeyville Sunday-school that our older readers will remember. Many of my old pupils were now fathers and mothers, having pleasant little homes of their own; and oftentimes the children would glance up at me smilingly,

bringing back pleasant recollections by the resemblance they bore to their parents. As I turned into our own dooryard there was still sufficient light from the bright sky off in the northeast; and I might almost say that I rode ten miles after sundown, and reached home before dark—that is, before it was *real* dark.

With the years of experience I have had in wheeling, I believe I can give some good advice. While this "second wind" is a wonderful and most priceless gift, like other blessings we should try to *use* it and not *abuse* it. In my trip through Missouri, especially on the ride I finished that Saturday night, I overtasked myself. In fact, I am not sure I am *completely* over it even now. In a recent number of the *L. A. W. Bulletin*, a writer made the remark that, whenever a wheelman finds he is unable to sleep nights, he has been overdoing, and I believe this is a pretty good rule. If you ride moderately the use of the wheel is conducive to sleep. If, however, under the influence of this new and may be heretofore unrecognized source of strength, the second wind, you keep on until the wheel seems almost as if it went of itself without any effort of your own, you may find that, when you try to go to sleep, sleep will not come. Another thing, very little strength is required on good roads, and roads that are not very much up hill; but climbing hills, especially if they are very long and steep, is hard on the muscular energy. You get along much easier, and enjoy the trip much more, if you get off and walk when the hill is so steep that it requires much effort, and accustom yourself gradually to long trips. When I commenced this spring, five or ten miles at first seemed to be enough. After you have ridden ten miles a day, however, for three or four days, you can make twice that or more, without much fatigue. Keep increasing the distance carefully and cautiously, and look out for excessive fatigue when undertaking to ride when the roads are in bad order. Be careful, however, about undertaking more than you can manage and do it easily. During extremely hot weather it is better to ride early in the morning, or during the twilight, as I have described. If you are not an expert in handling wheels, let some experienced person examine your wheel occasionally, and see that it is in nice order.

LATHYRUS SILVESTRIS IN BLOSSOM.

In passing a mass of plants this morning, June 21st, after a beautiful rain, I stopped and said, "Well, how in the world did sweet peas get among our lathyrus?" Looking a little closer I discovered that the beautifully colored diminutive sweet-pea blossoms were actually growing on the lathyrus. Why, a field of the plants would be literally gorgeous. Who was it that said it would not bear seed in this country? Well, we have not got the seed yet; but we have the blossoms. Stock seem to eat it about as readily as any of the clovers; and with its tremendous roots I can readily believe it will stand when once it gets root. And notwithstanding this, I should think it would not be a very big job to plow it under after it has been cut or pastured down pretty well.

BUGS ON SQUASHES, CUCUMBERS, MELONS, ETC.

Will you please give a remedy or preventive for the bugs that destroy cucumber, melon, squash, and other plants? If you know of any thing that will destroy these pests, or prevent their ravages, please let us have the benefit of that knowledge at once. J. F. WELTON.

Amboy, Ind., June 24.

Friend W., our mode of warfare is as follows: The minute the plants are up they are watched

morning and evening, and sometimes between times. Just as soon as a bug is found, the vines are treated to tobacco dust. If they still persist, tobacco dust is piled clear over the plants. Sometimes the plants grow up through the tobacco dust sprinkled over the hills. This usually suffices. However, when the bugs come in great numbers, and are very ravenous, or when the black squash-bug comes in great numbers, we try pyrethrum along with the tobacco dust. If they still are doing injury to the plants, then we get the wire-cloth screens, shown in our seed catalog, and fence them out. There are times when the latter seems to be the only real sure remedy; and even these must sometimes be watched to be sure that bugs do not come out of the soil under the wire-cloth screens. Many substitutes are recommended for these latter, such as boxes covered with cotton cloth or mosquito-netting. Striped bugs, however, often manage to get through the netting. If you fight them determinedly, both morning and evening, and show them you mean business, they will very soon give it up. This year we have not had a bug on cucumbers, melons, or squashes; if, however, you have so many things to look after, and they are neglected until they get under big headway, *you* may be the vanquished one instead of the bugs. Slugshot, and other preparations of Paris green, have been recommended; but they have never been as satisfactory with us.

STOWELL'S EVERGREEN SWEET CORN; IMPORTANCE OF GETTING THE SEED OF THE GENUINE.

My dear Friend:—I noticed in GLEANINGS last year, and also in this, what you say about Stowell's Evergreen corn. Your attention seems to have been directed to it last year for the first. I have had it from the time Mr. Stowell first put it on the market—twenty years and more ago. I consider the *genuine* the best sugar corn grown. I lost my seed several years ago, and have been trying in vain to get the *true* Stowell's Evergreen. There is a great deal sold for Evergreen that is not true.

This spring I obtained what I believe to be genuine. I have planted it, and it comes up nicely. I intend making my last planting about the close of this week or beginning of next, which will give table corn into the middle of October, unless a frost cuts it off. I generally have it that long when I have the genuine, as it remains fit for table use a long time after it begins to ripen. Knowing how hard it is to get the genuine, I send you some. The party I got it from told me they got it years ago from Mr. Stowell. Try it; and if it is genuine you will say you never ate better corn.

REV. JNO. L. JANEWAY.

Pawling, Pa., June 15.

Thank you, friend J., for the trouble you have taken to start me with some of the best seed. I shall plant it at once, and I hope we may be able to get mature seed from it.

CURRENTS—THE STEM BORER.

Now is the time to look over the bushes for the stem-borer. We have just finished an acre, and have found from one to fifteen stems cut off in one hill. A moth cuts them off and deposits an egg in the center of the stem, which, if allowed to hatch, will work its way downward through the heart, destroying the branch. We use a sharp knife and cut off about an inch; but in a month from now the worms may have worked down two or three inches. The moth cuts the new growth square off every time, so we cut on a slant. If we go over again, our work can be told at a glance from the work of

the moth. I consider this of as much importance as destroying the currant-worm.

Lodi, O.

W. R. GRANNIS.

ELECTROPOISE.

ROBBING SICK PEOPLE.

Mr. A. I. Root:—We have been victimized by the Electropoise fraud, and would like your advice. We had bought the concern about three months before your first expose of the same appeared in GLEANINGS.

We purchased the thing for a sister who had been troubled with heart disease for a number of years. In the fall of 1893 she was suddenly taken down with grip, and her heart trouble at once became very alarming. She was treated by our family physician all winter, and became some better, but still very weak, when our good doctor was taken sick and died. During the winter there was a kind gentleman here to see us, who had bought an Electropoise for his wife, and said she had been greatly benefited by it, and that he had cured himself of heart trouble, brought on by the use of tobacco, in a short time with it.

When he went home he sent us a lot of circulars, and I am sure he meant well by it, and was as innocent of fraud in the matter as you or I. I can truthfully say I had no confidence in it from the first; but sister read some of the pamphlets, then asked me to read, and we were "taken in" by the indorsement of clergymen, statesmen, and other people of prominence. Our doctor had told us if our sister lived until warm weather came she would get better, which she also did, although she gained strength very slowly. Well, along in May some time, she commenced treating with the Electropoise, and her strength kept slowly increasing. She was to report to the company after each course of treatment, which she faithfully did, and they wrote back to her telling her she was doing wonderful things, and advising her how to proceed. She followed their advice *strictly*, and on the 26th of August she dropped dead, right in the midst of a course of treatment. I can only say we were stunned, for she was the light of the whole household.

Aurora, W. V., May 27.

LEAH BEACHY.

Of course, no one could claim Electropoise did any harm in the above case, except that these people intrusted a dangerous case to the claims of a fraudulent thing. Had the case been turned over to a competent physician, the girl might have been well now; but no one can tell positively. I suggested to these parties that they state the case to the Electropoise people, and ask them to take the thing back and refund at least some part of their money. An interesting question comes in here. After the patient is dead, and the family have no further use for the instrument, how much would it be worth to the ones who sold it? It cost the purchaser \$25.00; but I am inclined to think the Electropoise people would hardly want to pay more than 25 cents. Rather than commit themselves, very likely they would refuse to take it back at any price. If they want to keep up the fraud, however, it might be a sharp thing for them to pay, say, \$15 or \$20 for it back again. Another point comes in incidentally. A man who had brought on heart trouble by the use of tobacco declared he was cured by Electropoise. Did he keep on using tobacco? If so, then here is a marvelous thing indeed. The instrument has such wonderful virtues as to cure a man from the consequences of a bad habit, and yet permit him to keep on. When we hear what they offer for the thing back again we will let our readers know.

The *Ohio Farmer* has just come to our aid; for in their last issue we find in their Medical Department the following:

While Electropoise, like every thing for cure of illnesses, has wonderful testimonials, we have failed to learn of any case of benefit from its use. True, chance of observation has not been extensive,

but the absence of report of some of those remarkable cures from the sick with whom we mingle is significant. To judge from examination of the instrument, would certainly condemn it. Its name indicates electrical action, but it has not the first appointment for this result. It claims to cure typhoid fever in from four to twelve hours—suppose they mean in the beginning. The price quoted is \$25 for a metallic device about the size of one's thumb, to be worn on the body. It is being much advertised and pushed, and many invalid readers of this paper will be tempted to subscribe for an instrument, as drowning men catch at straws.

It seems from the above that our regular practicing physicians do not meet with the wonderful cures certified by the testimonials.

Anybody who is thinking of building a greenhouse, even a very small affair, will probably find the June number of the *Market Garden* worth the subscription price of the paper for a whole year. This is a special number on greenhouse construction. You had better get one for a sample, any way, if you have not seen the *Market Garden*. Address the Market Garden Co., Minneapolis, Minn.

JAPANESE BUCKWHEAT.

We are having a good trade in Japanese buckwheat as usual this season of the year. So far we have not been obliged to advance the price as we have had to do for several years back. We still have a good stock in reserve, and our price for the present is \$1.20 per bushel; 2 bushels, \$2.20; 5 bushels or over, \$1.00 per bushel; bags included.

BUSHEL BOXES.

The season for using bushel boxes and crates is near at hand, and we would remind our customers that we are still prepared to furnish them at the old price. We have sold three thousand to one party in Pennsylvania, and another thousand to a New York customer, besides other orders, large and small. See advertising columns for further particulars and prices.

CATALOG OF HONEY LABELS AND RUBBER STAMPS.

For a time our supply of label catalogs was exhausted. We now have the new edition ready to mail to all who are interested and apply for one. It contains, besides the old favorites in honey-labels, several new and handsome designs. If you have a choice lot of honey, make it as attractive as you can by neat packages nicely labeled with your name and address. Then when the consumer wants more he will ask for your honey.

NEW 1895 EDITION OF A B C OF BEE CULTURE.

At last we are able to announce the new edition of the A B C of Bee Culture completed. There have doubtless been more additions and changes in this than in any former revision. Many new illustrations have been added. It will be furnished only in cloth binding. Price same as before, \$1.25 postpaid; or clubbed with GLEANINGS for one year \$2.00 for both, postpaid. To all those who have had a former edition at full price we furnish one of the new edition at \$1.00 postpaid, provided you say in your order that you have had one before.

FURTHER DECLINE IN BEESWAX.

During the last ten days there has been a decline of at least 2 cents per pound in the price of wax in New York market. The demand has slackened somewhat, and wax is more freely offered. We quote for the present 23c cash, 26c trade, for average wax delivered here. If you ship wax to us be sure to put your name on the package, and write us at same time; and please remember that we do not agree to pay more for it than we are paying when the wax reaches us. That is, if we should decide on a further decline July 15th, and you should start some wax to us on the 14th, which does not get here till the 18th, we do not pay more than the price

quoted the 15th. When wax was advancing in price, and some parties shipped when we were paying 28c., if it reached us when we were paying 30c the shipper got the benefit of the rise. It is a poor rule that doesn't work both ways. We mention this that none may be disappointed if they don't get as much as they expected, now that the market is declining. We have a good deal of wax on hand which cost us more than we can sell for now.

WANTED—SWEET-CLOVER SEED.

Tell us how much you have, and what you will take for it. At the price that is offered for it now it will pay to cut what goes to seed along the roadside, and it will very soon be making seed in most localities. It seems to me that some of the friends away out in Utah, where it grows all over the great sandy desert, might gather and ship us a carload. If you can not make a carload of seed, then give us a carload of sweet-clover honey, with some seed put in to fill up. There is no better honey in the world than that from sweet clover, and there is no plant that I have ever found that would grow with such thrift and vigor on the poorest, hardest, unfertilized, and uncultivated roadside. Besides all that, it is a valuable forage-plant. We cut it for our horses, and they eat it with more avidity now, since they have learned how, than any thing else in the line of green feed or cured hay. Some people call it a weed; but it is an exceedingly valuable weed. Let your stock get used to it and they will eat up every bit of it, even the hard and dry seed stalks. I believe it succeeds rather better on hard dry clay, or gravelly clay, than on sandy soil, for I never saw any of it in Florida—that is, to amount to any thing.

SQUASHES, RASPBERRIES, STRAWBERRIES, ETC.

June 28.—Well, the striped bugs have found the Hubbard squashes after all; but it was not until the vines had got out a yard or more; and then the bugs centered on the tender tips of the vine. The vines are too old to be covered; and, running so fast, it was hardly practicable to cover them with tobacco dust; so we just brushed the insects off the tender shoots and stamped them in the dirt. They have got now so they will fly as soon as anybody comes in sight. We got a small boy to fight them to the bitter end.

Our Gault raspberries from the first wood are so gnarly and imperfect as to be of no account. This was doubtless the result of the frost. The late crop, without question, will be all right.

We had thought once of discarding the Parker Earle strawberry; but under the influence of the recent rains, after all the other strawberries are gone the P. E. is doing nobly. We are going to hang to it for a late berry. We shall have strawberries sufficiently rooted so as to begin to fill orders—at least small orders—very soon after this reaches you.

THE CRAIG POTATOES.

They are now (June 29) doing finely; but the frost "sat down" very heavily on those we had started in the greenhouse. In fact, it hurt them rather worse than some that were up just a little way, that grew themselves outdoors. They are all, however, now beginning to show the distinct characteristics of the Craig as we knew it last year—strong, rank foliage, in spite of drouth or bugs; and we are just now mulching the space between the rows and around the hills with coarse stable manure—that is, the most advanced ones. This is the same treatment given the ten hills last season, you may remember. The manure is put on after the last cultivating, and just before the tops get so large as to be in the way of the manure.

DOCTORING WITH MEDICINE; A VALUABLE MEDICINE THAT I CAN RECOMMEND.

We have a liniment in our home that we have used for ten years or more that will cure or alleviate almost instantly a good many kinds of pain, such as toothache, earache, sore throat, rheumatism, neuralgia, bowel complaints, etc. This liniment, which we have used so long and like so well, is made by Dr. W. Wayland Wilson, of Billerica, Mass.

During a great part of my life I have been troubled with a chronic sore throat, that sometimes has a tendency toward quinsy. For many years I supposed there was nothing to do but grin and bear it when I felt it coming on. This is especially trying when I am obliged to talk, for talking greatly aggravates it. I have sometimes said I would give a

pile of money to anybody who would get me through this stage of a cold without that disagreeable hoarseness and pain in my throat. Well, "*Physianthropic Solution*" will usually give me relief in just about a minute, and it really seems as if the sore throat were driven away after using the remedy, say once in 15 minutes for an hour or two. When diluted with water, with a little sugar added, I find it rather pleasant to take. The rest of the family laugh at the idea of my liking medicine; notwithstanding, there was quite a complaint all around the neighborhood when our last bottle of "*Physianthropic*" was found to be nearly empty a few days ago. Why, the last spoonfuls were divided up like something exceedingly precious, and passed all around the neighborhood. I do not know whether Dr. Wilson will consider this a puff for his medicine or not; but if he would only sell it for 25 cts. a bottle, instead of 50 cts., I should feel a good deal more free to recommend that a bottle be placed in every household. Yet when one considers that a single dose will frequently save calling a physician, it can not be called an expensive remedy. He will, no doubt, send you a printed circular, telling all about it, with great pleasure. He used to be a bee-keeper, or had something to do with bee culture, years ago.

Queens

now ready by return mail, reared in full colonies, from the best honey-gathering strains in America, at the following very low prices:

Tested,	- - - each,	\$1.50
"	half-doz.,	8.00
Warranted Purely-mated,		.75
"	half-doz.,	4.25
"	per doz.,	8.00

If you want queens for business, get my old reliable strain.

FOUR OF A KIND.

A certain railway official wrote the officers in charge of fencing on four great Railroads, where "the Page" is in use, asking their "honest opinion" as to its value. He considered the answer so very favorable that he gave a large order for the Road he represented. The replies were confidential, but he stated that the strongest endorsement came from where "the Page" had been longest in use. If farmers took such precautions, those who furnish "cheap" wire fences would go out of business.

HONEY COLUMN.

CITY MARKETS.

CHICAGO.—*Honey.*—Some lots of new comb honey are coming forward, and sell at 14@15. The demand is very light, and will be for the ensuing two months. Extracted, 5@7, with sales chiefly around 6. Beeswax, 28.
R. A. BURNETT & CO.,
July 8. 163 So. Water St., Chicago, Ill.

PHILADELPHIA.—*Honey.*—The honey market is about the same as last quotations. Trade has been somewhat quiet, with only a small demand since the 1st of July. We look for a rather dull market until fall. We quote new-crop extracted, 5½@6½, in bulk; comb, 11@14, according to quality. Beeswax, 25@27.
WM. A. SELSER,
July 9. No. 10 Vine St., Philadelphia, Pa.

SAN FRANCISCO.—*Honey.*—Honey is a trifle firmer, as the crop does not turn out to be as large as expected. I quote 4½@5½ for light amber and white respectively. Comb honey, 1-lb. frame, 8@10. Beeswax scarce, 27@28.
HENRY SCHACHT,
June 24. San Francisco, Cal.

CINCINNATI.—*Honey.*—There is a good demand for extracted honey at 4@7, with a small supply on the market. Demand is fair for comb honey at 12@14 for choice white. Beeswax is in good demand at 25@30 for good to choice yellow.
CHAS. F. MUTH & SON,
July 8. Cincinnati, O.

CLEVELAND.—*Honey.*—There is no demand whatever for honey, and no receipts reaching us at this season of the year. We are holding No. 1 white at 12@13; extracted, water-white, 8. Beeswax, 28.
WILLIAMS BROS.,
July 8. 80 & 82 Broadway, Cleveland, O.

DETROIT.—*Honey.*—No honey in market to quote; but best new comb honey would sell for 14c. Extracted, 6@7. Beeswax dull and lower—23@24.
M. H. HUNT,
July 8. Bell Branch, Mich.

KANSAS CITY.—*Honey.*—Old stock of honey well cleaned up; some new comb in market. We quote new No. 1 white 1-lb. comb, 14@15; No. 2, 12@13; No. 1 amber, 12@13; No. 2, 10@11. Extracted, white, 6½@7; amber, 5@6. Beeswax, 25.
C. C. CLEMONS & CO.,
July 9. Kansas City, Mo.

KANSAS CITY.—*Honey.*—We are receiving new comb and extracted. New white comb, 14; extracted, white, 6½@7; dark, 4½@5. Demand very light. Beeswax, 22.
HAMBLEN & BEARSS,
July 8. Kansas City, Mo.

BOSTON.—*Honey.*—There is practically nothing doing in the honey line just at present. Nominal prices, 13@14 for comb, and 5@6 for extracted.
E. E. BLAKE & CO.,
July 8. Boston, Mass.

BUFFALO.—*Honey.*—Very light receipts as yet, and light demand. Possibly a few shipments of white comb could be sold at 12@13, possibly a few sales at 14, and other grades correspondingly lower. We can only suggest that people who want to find out what our market is, should make a few trial shipments, which will show just what we can do for them.
BATTERSON & CO.,
July 8. Buffalo, N. Y.

DENVER.—*Honey.*—Our honey market is quiet, there being so much fruit on the market just now. New honey is just beginning to come in, and we can quote same in 1-lb. sections at 11½@12½. Extracted, No. 1 white, in 60-lb. cans (2 in a case), 6c.
R. K. & J. C. FRISBEE,
July 8. Denver, Col.

ST. LOUIS.—*Honey.*—The honey market at present is dull. White and alfalfa comb honey, fancy stock, 1-lb. sections, 11@12; good to choice, 9@10; strained and extracted, in barrels and similar packages, 3@4; fancy white stock, in cans, 6@7. Beeswax lower—26½@27.
WESTCOTT COMMISSION CO.,
July 8. St. Louis, Mo.

ST. LOUIS.—*Honey.*—Honey market very slow. We quote comb, 10@12; extracted, in cans, 5½@6; in barrels, 4@5. Prime beeswax, 27.
D. G. TUTT GROCER CO.,
July 8. St. Louis, Mo.

FOR SALE.—White comb honey, 14 and 16c, on board cars.
G. R. ROUTZAHN, Menallen, Pa.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty.
J. P. IVY,
Secretary Bee-keepers' Association,
Phoenix, Maricopa Co., Arizona.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c.
OLIVER FOSTER, Las Animas, Col.

FOR SALE.—600 lbs. of comb honey, in 1-lb. sections, in 24-lb. shipping-cases, at 12c per lb.
EDW. SMITH, Carpenter, Madison Co., Ill.

No. 1 extracted honey in 50-lb. pails at 7c per lb.—\$3.50.

KIND WORDS FROM OUR CUSTOMERS.

I think GLEANINGS has the most solid comfort in it of any paper of its size that I ever saw. It is good to read to get inspiration and enthusiasm, and it is good to read when one wants to rest. Please continue your exposure of the advertised frauds. If all the best papers would follow your example in this respect it would be of great advantage to the world.
JOSEPH H. REED.

Benton Falls, Maine, May 18.

I have just received order No. 37,275 all right. I have not tried any thing but the Crane smoker, and that certainly is a daisy. The first thing I tried it on was the worst colony of bees I have. They always give me battle on every inch of their territory; but with the Crane smoker they turned after the first fire.
W. S. MASON.

Thorndale, Texas, May 14.

Friend Root:—You don't know how much good your little sermons which you publish in GLEANINGS from time to time have been to me. I used to think I was as good as anybody, and I did not have my name on the church-book; but when I read your sermons, and at the same time took the Bible as my guide, I soon saw that I was the chief among sinners; but I know now, thank God, that it was through the instrumentality of A. I. Root and God's word that I was placed on the solid rock, Christ Jesus.
FRED LEININGER.

Golden or Leather Queens

From the Queen Specialist. . . .

Golden queens from Duvall's best; dark leather queens bred from the celebrated Manum stock (queen mother selected and tested by him).

My drones are all bred from a colony that wintered successfully on summer stand without protection, bees gentle and excellent workers.

This colony is the result of seven direct crosses of golden Italians, selecting the most desirable for breeders each spring, *regardless of color*.

Nearly every queen mates with selected drones as there are no bees within several miles of my yard.

Duvall strain will produce nearly all 5-banded bees, Manum stock 3-banded.

Price 75 cts. each. Safe arrival guaranteed, and shipped by return mail if desired.

Money-order office, North Dana. Address

JAMES WOOD,

North Prescott, = Massachusetts.

SOUTH FLORIDA APIARY CO., New Smyrna, Fla.

WHAT have you to exchange for a 200-egg size Invincible Hatcher?

G. J. STURM, Mt. Erie, Ill.

TWO practical young farmers, both married, want to work some gentleman's farm on shares or for salary; prefer a good stock farm with some rich bottom land. We mean business. Write to-day.

MANLEY BROS., 197 Yale, Mich.

WANTED.—By a young man lately arrived in this country, a temporary or permanent opening in an apiary, or gardening business, preferably situated in the State of New York or contiguous States. Applicant knows something of the care of bees, and is fond of a healthy outdoor life. A cheerful home rather than salary an object. Is a trained clerk, with good recommendations.

Address C. C. DOORLY, 355 W. 31, N. Y. City.

WANTED.—To exchange invalid and fracture beds in hard wood, "Perfection" brooders and "Perfection" bee-hives, 8 to 12 frame capacity, contraction-device arrangements for comb honey—best in use; sections, foundation, frames, etc., for comb and extracted honey, pneumatic-tire Safety bicycles, good cross of poultry, chicks or year-old stock, and pure breed, all kinds; also chicken and duck eggs wanted, to hatch.

CHAS. L. HILL,
Box 495, Dennison, Ohio.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they wish to dispose of, we will insert notices as below, first insertion free of charge. After the first, 10 cents per line. We do this because there is hardly value enough in these queens to pay for buying them up and keeping them in stock, and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have 25 mismatched Italian queens for sale at 30 cts. each, or 4 for \$1.00. A good share of their bees are yellow.

ALBERT HINES,
Box 532, Independence, Ia.

Queens Sent Promptly.

in nuclei enables me to sell tested queens, of this year's rearing, at \$1.00 each, or six for \$5.10, and to send them by *return mail*. More than six queens (tested) will be sold at 75 cts. each, and will *probably* go by return mail unless the order is unusually large, but I don't promise that such shall be the case when the number ordered exceeds six. As a matter of fact, however, every order received in the last two months has been filled the *same day it came*. One queen and the REVIEW for \$1.51. Samples of the REVIEW free.

J. B. CASE, Port Orange, Vol. Co., Fla.

Vol. XXIII. JULY 15, 1895. No. 14.

STRAY STRAWS FROM DR. C. C. MILLER.

LINDEN gave my bees a taste, the trouble being the scarcity of trees.

I'M CULTIVATING a strain of bees that can live where there is no pasturage.

NO HIVE with more than eight frames has given a single pound of surplus for me this year.

"TOP SWARM" in England means a prime swarm. I don't think they ever say "bottom swarm."

GOLDEN CARNIOLANS. A correspondent requests the experience of myself or others with these bees. I've had no experience with them.

FOR NUMBERING HIVES, is there any thing better than movable tin tags? If not, what can I buy the numbers for? [Tagboard manilla, 50 cts. per 100.]

I SHOULD HAVE ADDED in a preceding straw, that my eight-frame hives did no better than the larger ones. Neither of them gave any surplus. So I can't come to any decision this year.

YEARS AND YEARS ago I got from Adam Grimm hives having spacing-arrangement with the principle used on p. 523. Have your spacers attached to the frame, not to the hive. [Yes, sir, every time.—Ed.]

WHITE CLOVER sometimes blooms late, making a second spurt as a kind of afterthought. But I never knew this late bloom to be used by the bees; whereas, they seem to work busily on the latest bloom of sweet clover.

ALFALFA looks almost exactly like sweet clover, unless I've been fooled as to what alfalfa is. Why has no one ever told us this? But when alfalfa blooms, the blossom is purple, and the seed-pod looks a little like a snail.

I DON'T CARE for color or bands on the outside of bees, only so they have the good working qualities inside. But the outside marks help me to judge something of the inside qualities. [But do you think lots of yellow is an indication of longevity and energy?—Ed.]

THE HIVE DISCUSSION will be interesting and useful for five years more, if it keeps bringing out good points. Now do you catch on, Mr. "Ed."? [Yes, but I want to be sure that a majority of our readers feel as you do.—Ed.]

I DIDN'T KNOW you were so heavily loaded, Ernest, when I came at you on that section-holder business, p. 517. Just as quick as I can get myself assembled together I'll come at you again. [I still have lots of ammunition left.—Ed.]

C. DAVENPORT gives some pretty good arguments, p. 513; but after all, I've a kind of notion that bees will put as much honey in a nail-keg as in the best hive, if left without help in each case. [But I was assuming that each was in an equally normal condition.—Ed.]

CEMENT-COATED NAILS are among the new things, and I didn't think I'd like them better than rusted nails; but I've been using them, and like them very much. The advantage of being able to use lighter nails with the same holding power is not a small one.

W. W. WOODLEY complains in *British Bee Journal* of foundation in center sections left untouched when others are sealed. He thinks it may be that wax sheets were too thick, and pressed when too cold, making the foundation too hard for bees to work—a hint for foundation-makers.

THAT PHRASE, "catch on," is slang for which there is no excuse; and after I get through using it in this straw it never ought to be seen again in GLEANINGS. "Understand" expresses the idea just as clearly and forcibly. [Beg pardon, it doesn't; but then, perhaps I can get along with the less expressive term.—Ed.]

"WHOOOP-DE-DOODEN-DOO!" That's what I said when I read a certain editorial item in GLEANINGS. Then I added, "So they've found out at Medina that there's value in sweet clover." If sweet clover, alfalfa, and a few more honey-plants, get a high seat as forage-plants, the future of bee-keeping may turn out better than the good old times before the wild flowers were all destroyed. [You shouldn't say "Whoop-de-dooden-do," because "hip, hip,

hurrah!" "expresses the idea just as clearly and forcibly." Do you c-c-catch on?—ED.]

THE PLAN of sending out with all supplies the right kind and quantity of nails to put the supplies together is one of the real comforts of a bee-keeper's life. Heretofore it was always a trouble to know what was the best nail for a particular purpose; and then when I did think I knew, likely as not I couldn't find at the store the kind I wanted.

YOU ASK, Mr. Editor, p. 512, "How would it do to have smaller membership fees and a larger membership?" Just the thing. Have the cost so small and the gain so large that every bee-keeper will want to be a member, even if he never attends a meeting. [This is an important question. I'd like to get expressions from others.—ED.]

MORE SUPERSEDURES are observed with clipped queens than with whole wings, perhaps two to one; for the man who has his queens clipped observes every case of supersedure, and the others are not noticed one time in five. But the queens with whole wings are superseded all the same. [We never clip, but our queens get "superseded all the same."—ED.]

NOTWITHSTANDING the dearth, June 8 I found at the Wilson apiary two colonies with queen-cells. I thought I'd settle their hash, and took away all brood and honey but two frames. Would you believe it? July 2 I found the insane things had both swarmed. At any rate, both old queens were gone, and a young queen had just emerged. [You shouldn't say "settle their hash," because it is slang. Eh?—ED.]

DR. RAMBLER thinks I wouldn't overeat if I deserted my wife and lived on crackers and cheese. I'm sure I shouldn't for long. A cracker, with its faint aroma of old grease, is one of the things I abominate, and

"Cheese is a mighty elf,
Digesting all things but itself."

If you'll excuse me, Rambler, I'll stick to the wife and the delicious bread she makes. [So shall I.—ED.]

ANENT that item on p. 526, isn't it true that bees always *think* they have a queen when they swarm? I had a queenless colony swarm, but the queen was removed not more than two or three hours previous, and I think they hadn't missed her. How long had your bees been queenless? [Some time; and that morning, previously all brood was taken away. We were preparing them for cell-building, and we wanted to get them fairly "howling" for brood and cells.—ED.]

How THICK is worker comb? On p. 525 Heddon calls it $\frac{1}{8}$; Cowan says "about $\frac{1}{8}$;" Dadant's Langstroth "about 1 inch," and Prof. Cook wisely says it varies. I think new comb will be found $\frac{1}{8}$ thick, (is it ever less?) increas-

ing in thickness with years of brood-rearing till it reaches one inch or more. The increased thickness is all in the septum, the depth of the cells being always the same. [Seven-eighths of an inch is a fair average for brooding-combs not over five years. I have measured scores of brood-combs from different hives, and have found them to register almost exactly seven-eighths.—ED.]

Our Hive Symposium.

SIZE AND SHAPE OF BROOD-CHAMBERS.

ARGUMENTS IN FAVOR OF DEEP HIVES FOR BROOD-REARING; DIVISIBLE BROOD-CHAMBERS NOT A SUCCESS.

By J. F. McIntyre.

Finding the ten-frame L. brood-chambers too small for this locality, Mr. R. A. Holley and myself have been experimenting this season with the object of deepening our brood-chambers without altering the other dimensions, so we could use all the combs and hives which we have on hand for supers, in case we decided to make a change. Mr. Holley was one of Mr. Heddon's pupils, and was prejudiced in favor of a double or horizontally divisible brood-chamber, so we tried two experiments. We each made a number of hives with 10 frames 7 inches deep, and several with 10 frames 12 inches deep, both the same length as the L. frame. After running through the breeding-season we have compared notes and agree exactly. The verdict is, that Dadant is right and Heddon is wrong; and we are both very positive that we want no horizontally divisible brood-chambers in our apiaries. On the other hand, we are both so pleased with the frames a foot deep outside I fear that, if some one doesn't hold us, we shall change all of our brood-chambers to that depth.

One thing that pleased us, and was rather a surprise, was the fact that the bees stored little if any more honey above the brood in the deep frames than they did in the shallow or L. frames. This gave the deep frames nearly twice the brood capacity of the L. frame, although only a fourth deeper. The shallow frames were a disappointment in every way. We could not produce nearly as much brood and bees in them, by any kind of manipulation, as we could in the deep hives. The queen did not pass readily from one section to the other; and, while she was laying in one section, the bees would store honey in the other. Alternating did no good. They would not remove the honey from the lower section, and place it in

the super according to theory. I think the reason was because the sections were too large for that kind of brood-chamber. I would say, if each section of a horizontally divisible brood-chamber is anywhere near the capacity of the queen, one or the other will soon be neglected, and filled with honey instead of brood.

Mr. R. Wilkin tried using two eight-comb L. brood-chambers (which were about the same capacity as our two seven-inch sections) on an extensive scale this season, and reports the same experience as we had with the shallow hives. The queen did not fill both sections satisfactorily, and soon neglected one altogether. From a non-swarmling extracted-honey standpoint, give us ten L. frames, twelve inches deep outside, for a brood-chamber.

Fillmore, Cal., June 1.

[Personally, I have never experimented with deep brood-chambers; but I have observed this: that we in our locality, only a few miles from H. R. Boardman, while following precisely the same methods of wintering indoors, do not have the same success that he does with his deep hive. While we lose indoors from 10 to 25 per cent, Mr. Boardman loses none. Perhaps the depth of brood-chamber may have something to do with it; but after all, take the reports as they generally run, there does not seem to be much difference in results, so far as wintering is concerned, between the Langstroth size of frame and a square one.

But friend McIntyre's argument is, if I understand him correctly, that more brood can be secured by using a deeper frame. Perhaps he is right.

His experience, and also that of Mr. Holley, agrees almost exactly with tests that we have made here at the Home of the Honey-bees; namely, that bees do not breed as well in divided brood-chambers as in one in which there is no division. Of course, we have tried only a hive or two at a time; but the results, extended over two or three years at different times, have always pointed the same way. Last year, when I visited Dr. Miller I found he had been experimenting with divisible brood-chambers—or, rather, a few shallow extracting-chambers that had been adapted for the purpose. If I remember correctly, he had difficulty in getting the queen to breed properly in two or even one at a time; and I think he then concluded that full brood-chambers were far better for breeding. The experience of Dr. Miller, of ourselves, of friends Wilkin and McIntyre, of Mr. Holley (a man who was formerly predisposed in favor of double brood-chambers), seems all one way. We should really like to hear from those who have tested this matter impartially—that is, from those who have no selfish interest at stake. GLEANINGS wants the truth, even if it should turn our supply department upside down.

Referring again to the cubical hive, here is another article quite in the same line with what has been already expressed by Mr. McIntyre, except that he would prefer a hive entirely cubical.

THE CUBICAL HIVE.

ADVANTAGES FOR WINTERING, AND SURPLUS HONEY; SELF-SPACING FEATURE, ETC.

By F. A. Snell.

I have read with deep interest the numerous articles which have been published in our bee-

journals for the past few months upon the form and size of bee-hives, or, more particularly, the brood-chamber. The articles have been ably written, and in that kind spirit so commendable. In the 28 years that I have read on the subject of bees through our journals, I must say the subject of hives, or forms of them, has not before been discussed with the force of argument which has characterized these of the last few months, by so large a number of solid, practical bee-keepers.

As I have been keeping bees nearly all my life, and in my present location 35 years, I have experimented a good deal on a small scale with hives of various forms and sizes. First, with straw hives; then with box hives of various forms; later on, with the Cox, Langstroth, American, New Idea, Eureka, and one having 12 brood-frames 18x22 inches, having no bottom-bar, combs seven inches in depth. I have also used the chaff hive. I have tried placing boxes for surplus in front and rear of brood-chamber, and at sides of brood; also on top in addition to side storing.

After testing the various ways and sizes of brood-frames I decided upon a hive holding ten American brood-frames, 11 $\frac{3}{4}$ inches square, inside measure, and ten to a hive, which strikes a medium between the deep and shallow brood-frames. All may not be familiar with this frame, so I will state that the top-bars are tight-fitting, with the exception of two openings 2 $\frac{1}{2}$ x $\frac{5}{16}$ inches, which affords passageway to the surplus-receptacles. The frames are spaced at the bottoms by large-headed eight nails, which keep the frames rightly spaced at all times.

Each hive-body has a movable side, opening half-way down from top. This hive may be tiered up as desired, and used for comb or extracted honey, as the apiarist may elect. I will give here some of the reasons why I prefer this form and size in a bee-hive. I can winter my bees more successfully; they pass through the spring months better, and are in much better shape when the honey season opens in June.

With me the colonies in deep frames almost invariably wintered well where supplied with good wholesome food, and a large per cent came out with the brood-chamber crowded with bees, while those in frames of 8 $\frac{1}{2}$ inches depth wintered poorly in the cellar or packed on summer stands. Every apiarist knows full well what success in wintering means. If we can only have strong colonies May 1, with brood-chamber well stocked with food, we are pretty sure to secure a crop of surplus if it comes, provided the form of hives is such that it can be placed to best advantage to the owner.

When the bees begin to whiten the combs along the top-bars in early clover bloom, as they will with a fair flow, the surplus room should be given. If the hive is of compact form, the bees will commence work in all parts

of the receptacle at nearly the same time, and, as a result, all sections will be completed ready for removal about the same time, or ready to raise up and insert an empty one between it and the brood-chamber, which I do, as I have practiced this for over 25 years, long before the sectional box was used. If the surplus honey is sealed at about the same time in all parts of the case, the case can be removed promptly when full, and present the neatest appearance possible. The surplus will be a little whiter in appearance where there is a little capped honey under the top-bar than where that space is taken by brood. With a small brood-nest it has always been my experience that but little comb honey can be secured, or that such will cast a swarm before work has been well begun in the boxes.

With a large shallow brood-nest, work was readily begun in the central part of the super, and gradually pushed to the extreme parts; but too much time elapsed ere the remote parts were completed—so much so that the central combs were badly soiled by travel of the bees from the dark combs so near at hand in the brood-nest. The same rule will hold when tiering. With the hive I use, no honey-board of any kind is needed for comb honey, as I have not yet had the first queen to enter the $4\frac{1}{4}$ sections. Four or five brood-frames can be moved sidewise at a time if desired, as is the case with closed-end frames, which is very convenient.

One point I omitted in the proper place is this: In the hive described above as my preference, I will say that, in a good honey-flow, I have often two or more supers well advanced before the colony casts a swarm. With two hives now in my yard, holding ten brood-frames $11\frac{1}{4} \times 8\frac{1}{2}$ inside measure, they have never had, when they survived the winter, one case near completion ere they sent out a swarm, invariably a small one, while the larger hives send out swarms that count, if any.

Economizing heat in a brood-chamber during winter and spring, and where the stores should be, I have written on in the future.

I have taken GLEANINGS from the first.

Milledgeville, Ill., June 17.

[We haven't heard from Doolittle on this hive discussion yet; and as this article is somewhat in his line of experience, we should like to hear from him. In the mean time we received another article from C. W. Dayton, also in the same line.—ED.]

THE BEST CAPACITY AND SHAPE FOR BROOD-CHAMBERS.

BROOD-CHAMBERS OF VARIOUS SHAPES AND SIZES IN MANY LOCALITIES; A GOOD ARTICLE.

By C. W. Dayton.

In 1882, in my apiary were 120 brood-chambers of 3466 cubic inches capacity, and contain-

ing 16 Gallup frames, $11\frac{1}{4} \times 11\frac{1}{4}$ inches. The inside measure of this hive was one foot in depth and width, and 24 inches length. It was designed to run the whole number of combs for brood-rearing up to the honey-harvest, when an upper story was to be added for extracting. Or, where the colony was operated for comb honey, the least-occupied combs were removed, and the space filled with two-pound sections. Such sections, being six inches square, four of them exactly filled the end of the hive when resting on the bottom-board. After three years' use it was found that not more than half of the colonies would become populous enough to require an upper story, and a large share of the extracting was done from a single story. About this time the ends of the hives were sawed off to reduce the number of combs to twelve. After a couple of seasons' use more, the brood-chambers were decided to be still too large because there were from three to six combs in the ends which contained honey instead of brood. The honey was wanted in the upper story. The hives were sawed off again, reducing the number of combs to nine. Then the brood-chamber contained 2088 cubic inches. I used that size of brood-chamber several seasons following, with perfect satisfaction so far as size of brood-chamber was concerned. The lower story contained brood in a compact form, and the super story caught nearly all the honey whenever the honey-flow was of any consequence. Yet it was found that attention was needed to provide sufficient stores for winter. This was usually done by inserting full combs of honey reserved for that purpose in extracting-time. By thus providing winter stores it makes a little more labor at the time of preparing the colonies for winter, but this is far more than regained by not being encumbered by unnecessary stores and combs in the hives in the busy season.

About one queen in 40 will appear to need two stories for brood; but I believe that such brood, if compactly disposed, might be all put in the one story.

In 1889 I began to look favorably upon the production of comb honey in one-pound sections; and the measurements of the Gallup hives were found exceedingly unsuitable for the adoption of the standard section. I was compelled to adopt the Langstroth measurements. For three seasons I handled 40 colonies, followed by one season with 250 colonies on Langstroth frames in both eight and ten frame hives. As a ten-frame colony is examined it would seem that the same amount of brood could be contained in an eight-frame hive; yet where a colony has been brought up in an eight-frame hive it seems to possess less available strength. The eight-frame colony does not occupy the super in greater force than does the ten. But when a ten-frame colony is contracted down to eight there is an increase of

energy in the super. This is too apparent for mistake. I account for it in this wise. In a ten-frame hive there is seldom any brood in the two outside combs. This leaves eight. There is also about one comb of pollen. If the pollen is scattered it is all the same—seven combs of brood. Apply the same deduction to the eight-frame hive, and it leaves five combs for brood. Allowing $1\frac{1}{2}$ inches to the comb, and measuring the lateral diameter of the brood-sphere, it is $7\frac{1}{2}$ inches, with a frame length of 17 inches. Now, the ten-frame hive exceeds the eight-frame, not by the two segments of the sphere's edge, like the slabs which are sawn from the log, but it is equal to two complete and square planks from the heart of the log. Two such combs of brood should enhance the strength of the colony one-half instead of one-fourth, as might at first be supposed.

The disproportionate length of frame may not cut so prominent a figure in a Southern California climate as in some of the colder latitudes—Colorado, for instance. In Colorado the nights, even late in spring, are cold. Then the middle of the days are very sunny and warm. When the hives face the south, the sun beats against the end so that it draws the brood up against the south end-bars of the frames, so that even the corners are all filled compactly with brood. I have seen brood so far to the south in eight combs, that, if six inches of the north ends of the combs were cut out, not a cell of brood would be disturbed. In Wisconsin there are more clouds during the days, and the days and nights are nearer of the same temperature. When two colonies were placed side by side with an inch of pressed chaff between the hives, the brood in each colony occupied the side of the hive nearest its neighbor. In this case the side combs contained brood on both sides, and more in quantity than any other combs in the hives. This happened on a cold unfavorable spring. The remote sides of the hives were unprotected from the inclement weather. If the brood will be placed far away from the cold end of a Colorado hive, why would it not be placed as far as possible from all four sides of the Wisconsin hive?

When the two frames are taken out of the ten-frame hive it has the effect to form a brood-chamber which is longer or slimmer in effect, than the original ten-frame chamber because of the squeezing or narrowing up of the brood-sphere. In other words, and in consideration of climates, kinds of weather, and different seasons, there is less consequence in *how much* space is taken away from a hive than in *how it* is taken away. Working against the natural tendency involves expenditure of heat and energy.

Had there not remained a broodless space in the ends of the combs of the ten-frame hive, the eight-frame hive would have never suggested itself. Nearly every one who went down

to the eight-frames has wished himself back again. Instead of lessening the number of frames, why not try the same number of less length? I have kept bees from a bread-and-butter standpoint in Wisconsin, Iowa, Colorado, and California, and have found the hive from which I never expect to change. Climates and localities do not affect its utility. It is the crossway Langstroth of ten frames, and 2020 cubic inches. The eight-frame L. contains 2100, and my nine-frame Gallup hive 1980 cubic inches. The eight-frame L. is large enough, but it is out of shape. After using ten $13\frac{1}{4}$ -inch frames to the hive for three seasons I am sure that the colonies become just as populous as with the $17\frac{1}{2}$ frame. It is calculated that food shall be stored in the ends of the long frames. In the short frame there is not. If I wished a brood-chamber to contain stores besides the brood, there would need to be 12 frames.

For winter, or for an abundance of stores at any time, a half-depth story remains on the hive, and nearly the whole supply of honey is kept in it. They very readily enter and refill a receptacle from which they are accustomed to obtaining their daily rations. The brood-chamber is $14\frac{1}{4}$ inches square, and it is $14\frac{3}{4}$ inches from the bottom-board of the hive to the top of the super, forming almost a perfect cube.

With the super there is always a good supply of stores, always a receptacle to catch a small run of surplus, and the surplus-receptacles are brought very close to the brood. I use two half-depth supers for extracting, so when one is being emptied there will remain one upon the hive.

I have arrived at this 2000 cubic inches capacity of the brood-chamber from two different starting-points in the last 13 years, while Mr. B. Taylor has occupied 45 years, and is not quite there yet. His frame is $8\frac{1}{4}$ inches deep. Had it been $8\frac{3}{4}$ inches, a wide frame of the same dimensions might accommodate two rows of $\frac{1}{4}$ sections. I should like to know of the advantages of that $\frac{1}{4}$ -inch.

I did not expect to keep bees when I came to California; but the ease with which they could be managed induced me to start with 43 colonies in the spring of 1893. Since that I have purchased none, but have disposed of (by sale and trade) 120 full colonies, and produced 12,000 pounds of honey, and am now extracting from 125 colonies.

Florence, Cal., June 25.

[And here is still another in the same channel:

ALWAYS GETS AT LEAST 200 LBS., EXTRACTED,
WITH A SMALL HIVE.

I want to say a word in favor of small hives. I never fail to get more than 200 lbs. of extracted honey from my small hive. I commence extracting between the first and fifteenth of May, and continue until the last of July. I ex-

tract once a week, and get two gallons from each hive. Some one may say, "Why don't you make a hive that you can extract four gallons from at a time, and take out your honey only once in two weeks?" I have tried that, and my bees would not fill one in a month; but they will fill one half the size in a week. Some may say that honey will not keep if taken out once a week. But I know better. It will in this climate. I never had a pound of honey spoil in my life, and I have extracted once a week during the honey-flow for years. I think much depends on a deep brood-nest.

I have three sizes of hives. The one that I get the most honey from is 12x12 inside; the brood-nest is 12 inches deep, with 8 racks. The extracting-super is 12x12, inside measure, with 7 racks. I had ten hives 12x18½ inside, 9 inches deep. I tried them two years, and they did very poorly. I cut them off to 14 inches long inside. Since that they have done much better. My experience teaches me that 9 inches is not deep enough for a brood-nest. I have kept a strict account of the amount of honey I have produced for 4 years, so I know what I am talking about when it comes to large and small hives.

I have taken GLEANINGS for a number of years. I like it better all the time.

Could not some one get a new pair of pants for Rambler? I am tired of those old plaid trousers.

JOSEPH I. EARLE.

Bunkerville, Nev., June 24.

[With all this available material before him, friend Doolittle ought to be pretty well loaded.—Ed.]

A SUPERIORITY OF QUEENS MORE THAN OF HIVES.

Friend Ernest:—I have read Mr. Davenport's article, and I think he shows a superiority of queens more than hives. Please note in Rambler's article, the 24-frame hive of Mr. Morley, 900 lbs. of honey cut out in one season, and your editorial, the improvements in hives tend to *less labor*, not *more honey*, and then think of keeping two men to *feed*. April 13th I selected 4 hives—two 8 and two 10 frame—am keeping a record of my work, and amount of honey from each. I will let you hear from them at the close of the season.

Sarasota, Fla., June 1.

S. C. CORWIN.

TEN-FRAME HIVE AHEAD.

We find the ten-frame hive is much better than the eight-frame hive that we have been using. We changed five colonies from eight to ten frames, and placed them with an equal number of eight-frame hives, giving the ten-frame hives two frames of foundation. Now for the result: Four of the five eight-frame colonies have swarmed, but not a swarm from the ten-frame as yet. Each one of the ten-frame hives has filled 28 sections. We have placed another half-section, filled with founda-

tion, under the one already filled. This was done a week ago. We find to-day, June 26, the foundation drawn out, and partly filled with honey. The eight-frame hive that did not swarm have filled 24 sections, and we have put on another half-story with foundation. As to the strength of the colonies in the spring, they were about equal, or in favor of the eight-frame. The ten-frame hive is far superior to the eight-frame in this one point—swarming. We will give you a full report later.

Morristown, Tenn., June 26. GLENN & CO.

RAMBLE NO. 136.

AT HYDESVILLE.

By Rambler.

In Hydsville we discovered one of the most renowned bear-hunters on the Pacific coast—Mr. Herbert Hansen, a Swede, and one of the early pioneers, a wool-producer and owner of thousands of sheep. He had killed 512 bears, 308 mountain lions, and a greater number of deer. In the early days it required eternal vigilance to protect the lives of the herds of sheep against the depredations of wild beasts; but in these more civilized days it requires hunters of experience and the help of trained dogs to hunt the bear. We three wanted to enjoy a bear-hunt; but circumstances worked against us, and we were prevented, and did not secure bear-skins for rugs as we desired to.

Our first Sunday in Hydsville, Bro. Pryal and I attended church, where we found a progressive Christian spirit. The pastor gave us a very good sermon upon Sabbath observance. He told his flock that, if people came to visit them, it was their duty to invite the visitors to attend the church services with them; and the young ladies were admonished in like manner to invite their Sunday-evening gentlemen callers to spend the evening with them in church. Now, Bro. Wilder was a "gallyant young man" with the ladies, and proceeded that evening to make a call. It is evident the minister's words were not lost upon the good young ladies; for in the evening Mr. Pryal and I were quite surprised to see Mr. Wilder meekly led in by two young schoolma'ams and safely sandwiched between them in the front seat in the church.

In my last Ramble I mentioned the fact that an apple-tree here will produce five barrels of apples in five years after planting. I have no reason to doubt the Blocksburg doctor's statement, for there are other things here equally marvelous. For instance, plant a schoolhouse anywhere in Humboldt Co., and in five years it will mature a crop of 50 schoolma'ams. The schoolma'am mania is so strong here that, in the rancher's families, triplets are not rare, and twins abundant—mostly girls. There are, therefore, more schoolma'ams to the acre here

than in any other like area in the State; and, aside from being mere schoolma'ams, I must say they were very smart and prepossessing. Up to our arrival in Hydesville, Mr. Pryal had appeared like a well-regulated, decorous, sedate, dignified, polite, "keep on your side of the fence and I'll keep on mine" sort of bachelor. He had given the fair sex generally to understand that he was engaged—to the Oakland waterworks; but here, after having the satisfaction of catching a few little fishes from Eel River, a change came over his demeanor, and for several days in succession he attended the county fair. Was this because he was interested in cabbages, corn, cheese, or the biggest rooster or the littlest hen? No; it was in the symposium of schoolma'ams, and Eureka was

By a happy combination of events, and a little sunshine in this land of the mist, I survived the wreck, brought order out of chaos, and what was left of us dropped into Port Kenyon, at the mouth of Eel River. Here, after getting Bro. Wilder into the warehouse, I had time to survey the country, and found it to possess the following features:

Eel River, after meandering through many miles of mountain scenery, mingles its waters with several other mountain streams, and departs mildly, just below Port Kenyon, into the Pacific Ocean. The rich bottom lands of the Eel River Valley afford succulent pasturage for many dairies, supporting all the way from 25 to 300 cows each. Creameries are abundant, and the resultant butter finds a ready

CLIMAX ENG.
CLYDE, O.

CREAMERY AMONG THE REDWOODS.

his theme (Eureka is where *the* schoolma'am lived). I could not, however, waste much time upon Mr. Pryal. Partner Wilder, since that fateful Sunday evening, was also afflicted with symposima'ams; there was trouble and some ominous threatenings in the air; roosters crowed; dogs howled; wind blew; rain descended; the hotel across the way caught fire; a weird earthquake rattled us, and at last that terrible symposium of schoolma'ams (was it a dream?) some younger and some older lugged Pryal and Wilder and our outfit off on their shoulders, leaving the Rambler in sackcloth and ashes. Whether it be a dream or not, that was the last we saw of Bro. Pryal. He and Susan B. vanished in the mist toward Eureka. Our poor dog, too, vanished into a sausage-factory.

market in San Francisco. In all of Eel River Valley there was not that cry of hard times we had heard elsewhere; and we found Ferndale, in the center of the dairy industry, a thriving town. Here, for the first time in our California travels, we found broad acres of pasture land that produced white clover in abundance; and surely in the land "where milk flowed and white clover grewed," there the honey ought to flow also.

A little search found the bee and the bee-man. There were several small apiaries of three and four colonies in box hives, but I found Mr. Inman, the bee-keeper of the valley. He had about 60 colonies. His hives were of the box order, with about 12 inches cubical dimensions. The old Harbison 2-lb. section was used

on this hive; and Mr. Inman, in selling his honey in the home market, cut it from the sections and used them over as long as they would hold together, and the most of them were black with age. Mr. Inman was not conceited in relation to his method of management, and desired modern hives and methods, and especially the light 1-lb. section; but considering his style of hive, and the fact that he was well up to 70 years of age, he was doing remarkably well to get 100 lbs. of comb honey to the hive in 1893, and in 1894 the season was off in Humboldt Co., as well as in other portions of the State, and from 50 colonies he obtained only 2500 lbs.

This excellent field of white clover is limited, being an area of only about ten miles square. Outside of this the bees obtain only a small amount of honey, principally from tarweed. Next to owning a large apiary, Mr. Inman seemed ambitious to use up the small apiaries around him. The nearest was only about 200 rods away. Mr. I. said that, when that feller came there, their bees fit like fury; but owing to his bees being very strong, the other fellow was *fit* out of seven colonies.

"Say," said he; "I could fix that feller's bees. Jest make a big swarm in a sugar-hogshead, and they will clean up his whole outfit."

Asking for further information, he explained that, by suspending a small hive of bees inside, near the top of a hogshead, they would increase and increase until they filled the whole hogshead, and they would rob out any apiary within three miles of them; and he claimed he had successfully tried it away back in New Hampshire; "and," said he, "by George, I've a good mind to try it on these upstart fellers around here."

Mr. Inman paid \$350 for his lot, 180x110 ft., and not in a town at that. Land in this valley is held at from \$500 to \$1000 per acre, and rents equally high.

Port Kenyon is the shipping-point from Ferndale. The little steamer Weeott makes regular trips to San Francisco, with butter, cattle, pigs, and merchandise; and, owing to the dangerous symposiums of schoolma'ams over the mountains, I resolved to return to San Francisco by steamer. The ocean was very rough, and had not subsided from the effects of the storms and earthquake, and the steamer lay out over the bar for several days, and finally on Sunday morning came into port.

All day the stevedores worked at unloading, and then loading. While this work was in progress I attended the little United Brethren church in town, and listened profitably to preaching, by a lady evangelist. There were several schoolma'ams present, and a large number of pretty milkmaids; but Bro. Wilder was safe in the warehouse, and the day passed without exciting episodes.

In the morning the captain said he was afraid the sea was too rough for his boat to cross the

bar. We were three miles from the shore, but could distinctly hear the hoarse roar of the breakers. About ten o'clock, however, the word was given for us to get our ponies on board. Our wagon and all its contents was lifted aloft with the hoist and donkey-engine, and gently dropped on board. The ponies clambered over the side on a sort of horse step-ladder. Mr. Wilder, with his past arduous experience on the bosom of the deep in remembrance, faced the bellowing ocean with a courage that was truly commendable.

The captain on the bridge felt his way carefully over the bar; two men at the bow of the steamer heaved the lead, taking soundings. One on the larboard side would shout, "Twelve fathoms, sir;" then from the starboard side would come "Ten fathoms, sir;" then it was 12 fathoms, then 15, then 20, and we were over the bar; but what a plunge our steamer made at 10 fathoms! Our ponies, near the forecastle, lost their feet, and went to the deck. They were up in an instant, and snorted as a breaker curled over the larboard rail and drenched them with salt water; but, once over the bar, the vessel moved steadily onward, only taking those long swells that are so soothing to the voyager.

As I have received so many benefits from Mr. Wilder's deer-hunting by claiming every time that *we* shot the deer, I will here give him the benefit of my expertness as a sailor, and say that *we* were not seasick during this two days' voyage. In San Francisco we transferred our outfit to the river boat, and continued our journey by water up the San Joaquin River to Stockton. Over 300 miles by water refreshed us, and here we were ready again to take to the common highways.

FEEDERS AND FEEDING.

SOME KIND WORDS FOR THE CORNEIL SMOKER.

By Emma Wilson.

About the last of May, as the bees had nothing to do we concluded we would do a little outdoor feeding at the home apiary, although we had thought the feeding finished for this spring. We filled the Miller feeders and piled them up six or eight high, leaving a good space open at the bottom so the bees could get at them. But, although the bees were swarming around them, they did not seem to find the feed, or at least they did not empty the feeders as fast as we expected. We then tried setting the feeders on the ground, one in a place, filling the compartment very loosely with hay, then putting in the sugar and water, leaving the covers off entirely. And, my! but didn't the bees just swarm about those feeders!

Into some of them we put very little sugar—about a pound to five quarts of water—and in others we put five times as much sugar to the

same amount of water. It didn't take the bees long to find out which were the sweetest feeders, and these were quickly emptied, while on those that were sweetened just a little they made very slow work until a little more sugar was sprinkled on, when it was fun to see them hustle. As soon as the feeder was empty we would pour in more cold water and then sprinkle the sugar on without paying any attention to the bees, although the feeders were full of them. We rather thought they would look out for themselves.

We thought we had struck a big thing in the way of feeders, for a dish of any kind could be used; but when we came to take the hay out of the feeders we found a good many dead bees in the bottoms of two or three of them. Just what the trouble was I don't know; but I rather suspect they were drowned when we filled the feeders. If we were doing it again I think we would fill the feeders at night after the bees had stopped flying.

White clover commenced to bloom pretty freely, and we began to put on supers the 29th of May. To be sure, the colonies did not show many signs of harvest; but we concluded from the looks of the clover that it wouldn't be many days before they would be needed; and as we had time then, we would put them on then and not be worried about it. But we would better have left them off; for, although the white clover is fairly abundant, there does not seem to be any nectar in it—at least, our bees are doing nothing at the present date, June 11.

We have fed a ton of granulated sugar since last September, and the prospect is that we shall have to commence feeding again. We have not had rain for weeks, and are suffering severely for want of it. A good rain might help, but I fear we need not expect anything from clover. I am in hopes we may get a little from basswood. Dr. Miller never counts much on basswood; but I believe there may be more of it than he thinks.

We received from Medina one of the new Corneil smokers. The first time we used it, about one of the first things I did was to burn my fingers; and while they were smarting I concluded I didn't like that smoker very well. I had used the Crane smoker with asbestos for so long that I had become rather reckless as to how I handled it. However, I have used the Corneil smoker a good many times since, and have not burned my fingers any more.

One very good feature of the new smoker is that it will burn for so long a time without going out. One morning lately we had a little work to do in the home apiary before starting for the Hastings apiary. I lit the smoker with a few shavings; and as the shavings were almost gone I rolled up a piece of an old hive-quilt, with a good deal of bee-glue on, and put it in the smoker. This must have been about 7 o'clock. We worked for about half an hour at

home, then started for the Hastings apiary, which is about five miles away. When we went to use the smoker after getting there, we found it burning all right. We worked there till about 3 o'clock in the afternoon without refilling or relighting the smoker; and when we were almost home Dr. Miller picked up the smoker and it was still burning all right. I meant to keep watch to see how long it did burn, but forgot all about it after we got home, so "I don't know." Now, I think it was partly the smoker and partly the fuel that kept it burning so long. It is lighter than the Crane, which is another point in its favor. The manner in which the fire-box is fastened on to the bellows makes it stronger and better than any thing we have had before. I have not had a chance to try it with a very hot and long-continued fire such as is used in smoking bees out of sections, but I imagine the Crane, with the asbestos, will then be ahead.

Marengo, Ill.

[I am sorry to know that you have had another poor season, or probably will have, from present indications. I can almost imagine that I see the season with you just as I saw it a year ago.

Using hay or grass over the syrup is a good idea, and not altogether old, I apprehend. A great many times, common pans may be put into the upper story of the hive, filled with syrup, and all that is necessary will be to pick up a good handful of grass and strew it over the surface of the syrup. I assume that, if it would do the work outdoors, it certainly would in the hive, where there would be less scrambling and crowding, resulting in the possible drowning of the bees.

Now with regard to the Corneil smoker. We have been experimenting with this smoker, the Corneil, for over a year; and I might explain that, along last winter, I sent one to Dr. Miller, telling him to test it thoroughly; and in *Stray Straws* for July 1 you will see he indorses it most highly. So you will see the smoker is no experiment; and, indeed, the principle has been tested thoroughly in Canada, and has, I believe, made a good showing on this side.

While the Clark is a most excellent implement for the money, we have heretofore had nothing between it and our very best smoker, the Crane. We have therefore devised a modification of the Crane and the Corneil. The method of supplying the blast to the fire-cup is Corneil's. The construction of the nozzle, hinging, legs, and fastening to the bellows, are improvements of the Roots and others, adapted to the Crane smoker and are now incorporated in the new smoker. In appearance the new Corneil resembles greatly the justly popular Crane. But you will observe the double-tube blast arrangement under the fire-cup, and next to the pair of hind legs, instead of the Crane valve. The bellows is not quite so highly finished as that of the Crane; but in another respect, with the exception of the shield, which is plain, and the Corneil blast arrangement, the new smoker is much like the Crane. This smoker will be sold at a medium price, and will meet the want of a very large number who do not care to go into the very best, but still want a little better than the cheapest. Its blast is not quite equal to that of the Crane, especially when crammed with fuel.

Now about the name—"Corneil." We have always, and more especially since his death,

held the name of a prominent Canadian in grateful remembrance. His scholarly ways, his pleasant manners at conventions, his fairness in discussion, have won the respect and admiration of bee-keepers wherever he has been. That man is S. Corneil. Some time ago he showed the advantages of the double direct-blast arrangement when attached to smokers; and while I did not think, and do not now, that it has the strength of the Crane, it goes a long way toward being as strong, and its method of application is very much cheaper. The only thing about the new smoker—that is, Corneil's—is the blast arrangement; but we always like to name a new implement after some good man who has contributed no small part to the vital function of the implement itself. In like manner it has been a pleasure to us to name our swarm-hiver after A. E. Manum, who first devised the tripod arrangement. In a similar way it has given us exceeding pleasure to name one of our recent extractors after Mr. Cowan; and rightly, too, should it be named the Cowan, because it employs the principle that Mr. Cowan first made public. It was a pleasure also to designate what we call our very best smoker a Crane, after that most excellent bee-keeper, lecturer, and scholar, J. E. Crane, who indeed devised its most vital features. In a like manner, also, it is now a pleasure to christen the new smoker after Mr. Corneil. All the men I have mentioned, after whose names we have christened apiarian implements, are and have been bee-keepers of high standing; and it is indeed a pleasure, dear readers, to give deserving honor to whom such honor is surely due.

VARIATIONS IN BEES.

The following is an extract from "Insect Life," published by the U. S. government, and edited by C. V. Riley. By the way, every bee-keeper and fruit-grower should get this periodical, and read it. As it is furnished free by Uncle Sam, there is no excuse for any man remaining in ignorance as to the nature of our insect-enemies, and how to destroy them.

While the different species of the genus *Apis* differ in size, coloration, temperament, and habit, there are comparatively slight variations in structure—a necessary inference for every zoologist. But if we study the other species of the family *Apidae* we shall find every variation, and ob-

tain a very good idea of how the special organs in *Apis* may have been evolved and perfected from simpler organs in other genera. This may be illustrated by a few sketches of some of the more important structures, as, for instance, the polleniferous organs and the wax-producing apparatus. (See Fig. 25.) The figures very well illustrate the fact that the modification of structure and hairy vestiture, which facilitates the collection and transportation of pollen, while exhibited perhaps in the greatest perfection in the hive bee, is nevertheless an evolution from similar structures possessed by other species of social bees, such as the *Meliponæ* and *Bombi*, and still more remotely from such as are possessed by the solitary bees.

In the production of wax, the hive-bee exhibits a lavishness not found in any of the wild bees, not excepting the species of *Trigona* and *Melipona*, which approach it most nearly in social economy. As a result we find that the wax-secreting organs of *Apis* are much larger than in any other wax-producing bees. In *Bombus* they are greatly reduced and otherwise different in structure, resembling, however, very closely those obtaining in *Melipona* and *Trigona*. In the solitary bees, which produce no wax, these specialized structures are entirely wanting. These solitary bees, no matter in what situations or of what material they make their cells, generally store them with honey or pollen, and, after depositing an egg, cap the cell and leave the young larva to care for itself. The habits of the social bumble-bee (*Bombus*) are but a step in advance, as the larvæ are developed in a mass of pollen and honey, in which they form rather imperfect cells. When full grown each spins a silk cocoon which is thickened by a certain amount of wax, which is added by the adult bees. The females labor, and several co-operate in the same nest. In the bottle-bees (*Melipona*) a still further step is seen, as the cells, of a rather dark, unctuous wax, are formed into regular combs, and are somewhat imperfectly hexagonal. They are, however, in single horizontal tiers, separated and supported by

intervening pillars, more like the nests of the social wasps, and the cell is sealed after the egg is laid upon the stored food, just as in the case of solitary bees. The honey is stored in separate flask-like cells, and but one queen is allowed to provide eggs.

HOW TO GET RID OF FOUL BROOD.

THE FOUNDATION PLAN EXPENSIVE; A PLEA
FOR THE PHENOL TREATMENT; DO
QUEENS CARRY THE INFECTION?

By Wm. F. Clarke.

I consider this the most important practical question at present before bee-keepers, and I should like to say a few words in reference to some editorial remarks on the subject in last issue of GLEANINGS, page 527. I hardly think the suggestion that intelligent and progressive bee-keepers offer to furnish foundation, frames, and new hives to owners of foul-broody stocks, is at all likely to be carried into general effect. What a wealthy firm can do in this line is no rule for individuals who are keeping bees on a limited scale. It seems to me that what is necessary in order to secure a riddance of this fell disease is, first, to find some cheap and easy method of cure; secondly, to find an effectual preventive; and, thirdly, to thoroughly disseminate a knowledge of the means of prevention and cure among bee-keepers.

What is now generally known as the McEvoy cure is too costly for general adoption. The expense per colony is about as follows: Two sets of frames, one set of starters, and one set of full sheets of foundation, from \$1.25 to \$1.50. If the suggestion made in GLEANINGS is followed, the cost of a new hive must be added, say \$1, making \$2.50. The work can be satisfactorily done only during the honey-harvest, and consequently it involves a loss of all surplus that season. For this item add \$5, making a total of \$7.50 per colony.

When I started my present apiary, which was certificated by the Foul-brood Inspector as perfectly healthy, I had a bee-keeping neighbor whose apiary consisted of 80 colonies which were known and admitted by him to be foul-broody. The inspector chalked 14 of those hives to be burned, and ordered the remainder treated on the costly method above mentioned. By the time the work was done the apiary was reduced to 40 stocks. This reduction of stocks adds another and a large item to the cost.

GLEANINGS deserves commendation for the full information it has given its readers concerning various methods of drug cure and prevention. It is, I am persuaded, along this line that we are to work out the general salvation from foul brood.

I have been greatly astonished at the failures reported by bee-keepers who have tried the Cheshire recipe; but a long and painful experience has taught me the secret of this general failure. It has resulted from the refusal of the bees to take the medicated syrup. I have not met with one case in which a bee-keeper has reported failure after the bees had taken, stored, and fed upon phenolated syrup. Mr. Cheshire virtually predicted this failure. He said in Vol. II., page 562, of his great work:

"Ligurians refused the food, and succumbed to the disease." * * * "To place the food with added phenol, on the hive, will, however, do nothing in the greater number of cases. If honey be coming in, the bees will not touch it; but open the stocks, remove the brood-combs, and pour the medicated syrup into these cells immediately around and over the brood, and the bees *will use* a curative quantity of phenol." As I read these directions I gathered that the bees *would use* a curative quantity administered in the above manner, even when honey was coming in. But I could not succeed in making them do it. However, I subsequently discovered a couple of wrinkles which I am very anxious to make known, in order that bee-keepers may experiment in view of them. The first is to feed the phenolated syrup at a time when there is absolutely no honey coming in. Take advantage of the period of complete cessation of nectar-yielding, when the bees are ravenous for food, and are like a hungry man who will not be particular to get quail-on-toast, and other epicurian dishes.

The second wrinkle is to take care not to medicate the syrup too strongly with phenol. I overlooked in my first trials this pregnant sentence: " $\frac{5}{100}$ dispatched the bacillus quickly when honey was coming in, and $\frac{7}{50}$ when it was not." I found that, even in a time of scarcity, the bees refused the $\frac{5}{100}$ decoction, and I kept diluting the syrup until they took it freely. I do not wish to "holler until I am out of the wood," and I am not yet prepared to tell fully "what I know" of foul brood; but I do not want to delay until another season at least a partial detail of my experience. The present season is so unfavorable that considerable feeding will have to be done this fall; and I want to say to bee-keepers who know or suspect that they have foul brood, *do your feeding not later than August, and medicate your sugar syrup with phenol anywhere between the $\frac{5}{100}$ and the $\frac{7}{50}$.* It is my firm belief, which it will take a large amount of rebutting evidence to shake, that, if these rules are strictly followed, Cheshire's recipe will cure any case of foul brood that is curable. I believe, too, that the same prescription will be an effectual preventive. The cost of the phenol is a mere bagatelle, and need not be made account of at all.

There is a great deal more I could say on this subject; but "my time is not yet." Longfellow says in his Psalm of Life, "Learn to labor and to wait," which is what I am trying to do. There is only one thing more I feel it necessary to say now, and that is this: I am afraid your confidence in the safety of taking queens out of foul-broody hives, and introducing them into healthy ones, is misplaced. You say a very few cases of queens carrying foul brood from one colony to another have been reported; but there are so many other ways in which it could have been carried that you are inclined to

doubt them all. Surely you have never carefully read Cheshire, Vol. II., pages 547-549, where it is proved to a demonstration, by dissection and microscopic examination of queens, that the *bacilli* have been found both in the ovary and in the egg. In one case, when a half-developed egg was crushed flat, *nine bacilli* were quickly counted. I pray and beseech you not to take any more queens out of foul-broody colonies for the purpose of introducing them to healthy ones. If we are to get rid of this terrible scourge we must run no risks, but, in all cases, "make assurance doubly sure."

Guelph, Ont., July 3.

[If Mr. McEvoy recommends treating colonies during the height of the honey-flow, of course this would make an expense depending upon whether the season was good or not. But my experience has shown that foul brood is much more apt to break out before or after the honey-flow. It is when bees eat their stores clear down that they get to where the diseased germs are. So I think we may say that in most cases, at least, treatment will be administered when there is no honey-flow. But suppose we do treat at this time. As seasons have been uncertain of late, \$5.00 would be a very large estimate of the actual loss. I think, therefore, we should, in the great majority of cases, throw out the \$5.00. I only suggested furnishing a new hive; but the one diseased can be boiled just as well as not. If this is accomplished during odd hours, the estimate you give could not run much above \$1.50 or \$2.00. So the foundation plan is not so very expensive, after all. And we must assume that the treatment by medication must cost something in the way of the drug in the first place; medicating the syrup; feeding, and the cost of the syrup itself. Practically, then, there would be no very great difference.

With regard to the phenol, I personally tried it diluted 500, 1000, 750, and, in fact, all sorts of dilutions; and in nearly every case it would apparently check the disease, but not in a single case do I remember that it *cured* it entirely, *in the long run*; and when we were fussing with phenol, foul brood in the mean while got pretty well scattered over our yard. The economy of the foundation plan rests in the fact that it is an absolute cure; and if every colony is treated at once, before the disease gets a start, the expense can not be very great. And still again, my own experience with phenol was corroborated by that of a number of correspondents from Australia at the time; later on by Prof. Cook and many others.

I feel quite sure that in your own case you will find the phenol is only a temporary relief, and not a cure. But I thoroughly appreciate the point you make—that, *if* we can avoid the expense of foundation, waste of brood, and general interruption to the colony, by any method of medication, we should hail it with delight; and notwithstanding all the reports that I remember to have read seem to be against the phenol, I am still open to conviction.

My advice to owners of large apiaries was meant to be a suggestion, because they can well afford foundation and frames for a couple of hives, free of charge, rather than run the least risk of the disease being transmitted to their own yard. In other words, we can well afford to take a stitch in time, even though that little stitch costs a little something, in order to save nine stitches later on.

With regard to the disease in the ovary of the queen: I would not deny that Cheshire found

spores in the ovaries of queens;* but certainly we never had a case that was transmitted that way when we were experimenting along that line; but of course I would not carry the impression that it is wise to make a practice of taking queens out of diseased colonies and putting them into healthy ones. I would always take the safer course. It is not wise to drive too near the brink, even though we feel *perfectly sure* that we can drive within an inch or two of that brink and not run off.—ED.]

CALIFORNIA ECHOES.

By Rumbler.

One person has found honey a dear article in Riverside, Cal. He stole sixty sections from an apiary, was caught in the act, and the justice put the price of honey right up to \$1.00 per section, \$60.00, or sixty days in jail. The thief is in jail.

When uncapping honey for extracting, fasten a whetstone to the place where you wipe your knife. In wiping over the stone, the knife is kept to a keen edge. I am indebted to Mr. Schaeffle, of Calaveras Co., for a part of this idea. [Good. Paste this in your hat (head).—ED.]

If I have ever said any thing reflecting at all upon the nectar-giving qualities of white sage, I will now take it all back. This year my observation has been where mountains are covered with it, and the bees have gathered tons of the most beautiful honey ever deposited upon the tongues of mortals. White sage is fully equal, if not superior, to either black or purple sage.

I suppose our Eastern friends desire to be kept posted on the length, breadth, and thickness of our honey-yield. It continues discouraging to us. Wild buckwheat, upon which so many depend for the last yield of the season, seems to be withering. It has the appearance of insect-work in the stalk, sapping the life from it. Again I reiterate the remark that our yield will not approach that of 1893.

M. H. Mendleson, of Ventura, does nothing in the management of bees in a small way. He moves his bees to the bean-fields, and his wagon for moving them will carry 100 colonies. With this rig it takes but a short time to surprise the blossoms of a new field with a great force of busy workers. Bro. M. puts the yield of Southern California at half a crop, and advises bee-keepers to hold their honey for 5½ to 6 cts. per pound.

*I am one of those who, though recognizing Cheshire's great work, do not believe that he was infallible in all things. You remember how severely he criticised his cotemporaries for the mistakes they had made. Later developments have shown that he was quite as capable of such sins as they. The man who pulls motes out of his brother's eye is pretty apt to have some tolerably big ones in his own. Hence, while I do not deny his statement here, I can't quite swallow it when real practice seems to be at variance with what he saw or thought he saw in the microscope.—ED.

When John H. Larrabee left his apiary in Vermont to serve the government as an heroic "apistical experimenter," his brother Walter stepped into his shoes as a worthy successor at the home apiary. After a year's service, John left the government position for a higher walk in life, and walked into matrimony. Walter, like all observing bee-keepers, noting the felicitous condition of his brother, has also recently walked into matrimony. Walter and his helpmeet, I believe, stick to the bees and the farm, while John runs a bicycle-factory in Lansing, Michigan. [Good for Walter! The force of habit is strong. Beware, Bro. Rambler.—Ed.]

When Mr. Alpaugh returned to Canada, from his travels in the Golden State, he gave some of his experiences in the *Canadian Bee Journal*; and among other things he said he found a condition in a certain California honey-house that he would not divulge, for it would amuse some Californians, and it might make some mad. Well, I have waited for the secret to come out; and, behold, Bro. Gemmel the tale unfolds before the whole Oxford Bee-keepers' Association, to their evident amusement. Bro. Alpaugh found a skunk in a can of honey—that's all. Why, my Canadian friends, that is a common occurrence. That particular apiary was infested with foul brood, and the owner was making a disinfecting compound to be used in the early spring. "Mephitis mephitica" and honey I would recommend to Inspector McEvoy, or any Canadians afflicted with foul-broody apiaries. It is easily prepared, as Mr. Alpaugh witnessed.

A petition is out for governmental interposition in behalf of *Apis dorsata*. Prof. Benton says it cost not much less than \$1000 for his abortive effort to import the great bee. Of course, Prof. B. does not wish to abort again on his own capital; but it seems to me that, if *Apis dorsata* is worth any thing to bee-keepers, it is a mighty poor national industry that can not land the bee here on its own account. [Are we sure *Apis dorsata* would be of any practical value once introduced? I have the impression from what I have read of them that they are exceedingly hard to domesticate. If such is the case, would it not be better to ask for appropriation in much more needed directions? We need, for instance, an apicultural station under the national government, and Frank Benton would be a good man to conduct it.—Ed.]

"There comes a tenderfoot. Now we shall have some fun," said a bee-keeper to his helper; but when the supposed tenderfoot emerged from the foliage of a gum-tree near the apiary, he was veiled ready for emergencies. "Not much tenderfoot there," said the bee-keeper, "and no fun." This leads me to remark: Why do we laugh with delight to see a fellow-mortal stung by our bees? and the more dignified the unlucky man is, the more intense the laughter. I think the reason is found in the fact that

dignity stands no show before the angry hum of the bee. A reverend gentleman is supposed to be very grave and dignified; but let the sharp persistent hum of half a dozen bees sound close to his ears, and dignity is instantly dethroned. He swings his arms with greater energy than when pounding the pulpit; ducks his head, and, with hat toppling off, plunges into the neighboring bushes, with coat-tails in the air. Perhaps he comes out with an eye swelled shut; but the only sympathy he gets is a laugh and a shout—"Got stung, hey?" A cool, collected bee-keeper, then, should be the most dignified man on earth.

SHAKING BEES FROM OFF THE COMBS.

Question.—I am bothered very much in getting bees off their combs when I wish, for any reason, to change combs with certain colonies, and in extracting. We are told to shake them off, but there must be a peculiar way to shake them; for, shake as hard as I can, I get very few off, and generally make them angry when I try it. Will you please tell us in GLEANINGS how you get bees off their combs when you wish to?

Answer.—In changing combs in the apiary I always shake the bees off, or the majority of them; and with hybrids and the blacks, every bee can be shaken off, providing the combs are built in the frames as they should be, so that they fill the frames full and are in a straight and even line with the frame, thus giving the bees no little holes or open space along between the bottom-bar to the frame and the comb, into which they can crowd in such shape that they can not be dislodged as long as they stay there. After having the combs built out as above, and desiring to take a comb away from the bees, I place the projecting ends of the frame on the ends of the two middle fingers of each hand; and then with a quick upward stroke throw the ends of the frame against the ball or thick part of the hand at the base of the thumb. As the frame strikes the hand, let the hands give a sudden downward motion, which makes the shock still greater. As the frame strikes the fingers it is again thrown back against the hand, and so on till all or nearly all of the bees are off. The principle is, that the bee is on its guard all the while to keep from falling off, thus holding on tenaciously so as not to be easily shaken off by any motion which tends to throw it down. By a sudden stopping of the upward and a quick downward motion, the bees are thrown off their guard and dislodged from the comb in an upward direction. I do not remember of ever having broken a comb by

shaking it as above described, although some claim that they can not shake bees off their combs without breaking the combs more or less. In this way I have no trouble in shaking off black bees and hybrids; and if we disturb the Italians, causing them to fill themselves with honey, they can be shaken from their combs about as easily as black bees. But even if we can not afford to wait until they are filled with honey, four-fifths of them can be shaken off. To get off the remainder, one of the different bee-brushes, now to be had of supply-dealers, will finish the job very quickly; or, instead of the bee-brush, you can use a turkey or goose quill to fully as good advantage by trimming off about one-half of the wide side, so that the feather part will not irritate the bees. Of course, this will appear a little awkward at first, but will soon be found easy enough. In working for extracted honey I used to adopt the same plan to rid the combs of bees, and succeeded very well, although it is much harder work on account of the combs being so heavy. With our perfect escape-boards of the present time, it is not necessary to thus shake the bees from the combs when extracting, for the bee-escape cleans the combs of bees perfectly, and is the thing to use where all the combs in any upper story to any hive are to be removed.

HOW MANY ENTRANCES TO A BEE-HIVE?

Question.—In making hives, how many entrances should be allowed? I am told that, beside the front or main entrance at the bottom of the hive, an entrance should be made at the rear also for ventilation, to be opened during hot weather, and one near the top of the hive to be open at all times when the bees are storing surplus honey, so they need not have to travel so far to carry honey from the entrance to the top of a second or third story hive. What is your opinion in this matter?

Answer.—Regarding the ventilation matter, I much prefer to make the entrance large enough to give all the needed ventilation in times of extreme heat, and have it so arranged that it can be easily contracted to meet the requirements of the smallest colony when desired. My reasons for preferring are that, unless the rear entrance is closed during cool nights, it makes the hive so cold by the draft of air thus caused, that the bees can not work to advantage at comb-building or evaporating nectar; and, worst of all, the bees get a habit of using this ventilator for an entrance, so that, when it is finally closed, the bees which have been accustomed to use this as an entrance to the hive go out at the regular entrance, but return to the old place only to find it closed, thus causing a great commotion and loss, as they know of no other place of getting into their home, having so marked on their first flight. As to the entrance into or near the surplus apartment, any one arguing that such is a necessity shows a lack of thorough knowledge of

the inside workings of the hive. The bees which gather the honey are not the ones which deposit it in the cells, as I have several times proven by taking away a queen of one variety of bees and introducing a queen of another variety. For instance, I once took away the queen of a black colony in June, and noted the time the last black bee hatched, and when the first Italian bee emerged from its cell. As young bees do not gather honey till they are sixteen days old, when the colony is in a normal condition, on the fifteenth day after the first Italians hatched none were seen going in and out at the entrance but black bees, while an examination of the surplus-apartment, in which bees were briskly at work building comb and depositing honey, showed scarcely a black bee there, but all were Italian. And this is only one instance among many which have proved the same thing. Consequently I am opposed to more than one entrance to any hive.

[I sometimes practice your method; but more often I pick the frame up, grasping the projecting end of one end of the top-bar; and, doubling my fist, I strike the top-bar one sharp quick blow at a point where there are no bees. I find I am more successful when I take the bees by surprise; because, the moment they are jarred once, they will hold to the cells tighter than ever. I am also careful not to smoke them much if any before this shaking-off process; otherwise the bees stick their heads into the cells and take a firm grip.—Ed.]

FEEDING BEES SUGAR SYRUP IN THE SPRING.

Allow me to say one word with regard to the management of bees in spring. Some few prominent bee-keepers, with more zeal than wisdom, recommend feeding bees, at this season of the year, large quantities of sugar syrup, so that, when they begin to work on clover, the hives are already full of syrup, and consequently the first, and, in fact, all the clover honey, must go to the surplus-boxes. Now, all this sounds very nice, and possibly some beginners may follow such a course until a little more knowledge on the subject convinces them of the folly of that kind of practice. I will give my reasons why not to do so.

When the surplus-boxes are put on to make room for the queen, the bees will usually move a large part of the stores from the brood-chamber to the surplus-apartments, and thus you see you have an adulterated instead of a pure article for the market. But it has been said that a little sugar won't poison anybody. Very true, it will not. But to do so, will poison your conscience; lower yourself in your own estimation, blast your reputation, and injure the honey-producing interests of the country. The people want a pure article, and will buy it and use it liberally, when convinced of its purity. Every business man, or nearly so, to whom you offer honey, will ask you if it is pure. Now, if there is the least taint of sugar about it you must say so or

He. But if you begin to explain that there may be a little, etc., why, the game is up and you are out, for no respectable dealer will touch it, unless you can vouch for its purity. True, you could make a big report at the close of the honey season; but I am proud to believe that no Canadian bee-keeper would feel very happy over a crooked report, however large, consisting of sugar and honey.

Let us most religiously see to it that Ontario honey shall stand extra No. 1, in the markets of the world. Work hard and make your honey crop as large as possible; but never sacrifice quality for quantity.

Belmont, Ont., May 4.

—S. T. Pettit, in the *American Bee Journal*.

Mr. Boardman, to whom we sent the above extract, replies:

Read carefully on page 345 of GLEANINGS the last part of my article on feeding before the honey season. I believe it is true, and so accepted by all fair-minded bee-keepers—that stores once sealed over in the hive will not be again unsealed during the season unless some extra inducement is brought to bear upon the bees to make them do it. We all know how frequently the extractor has been recommended for this purpose when the queen has been restricted for room. Reversible hives and reversible frames are to induce the bees to unseal and remove their stores. So well established is this fact that I consider it a waste of time to discuss the matter.

H. R. BOARDMAN.

East Townsend, O., June 6.

CELLULOID TABLETS FOR NUMBERING HIVES.

Mr. Root:—I inclose a little piece of celluloid, with the request that you investigate the practicability of using such material for numbering hives. It can be had in any color. White, of course, with black numbers, would be the best for hives. It seems to me it would be a very desirable material for that purpose, as it would not be injured by the sun's rays, nor by moisture. I wish to get numbers for about 100 or 150 hives, and really don't know what to get nor where to get it. To get a painter to paint them on metal would be too expensive; ordinary cardboard might answer, still it would not be very durable. There ought to be quite a sale for such things if they can be furnished at a reasonable price.

G. F. HYDE.

San Diego, Cal., May 26.

[The great trouble with such tablets is, they are too light and expensive. Painted tin ones, as spoken of by Dr. Miller, would be, I think, much better. Dr. Miller, who uses such tablets, and to whom your letter was sent, writes as follows:]

I never thought of the thing before; but I believe Mr. Hyde's suggestion is a good one, to have numbers for hives ready made. One who knows the advantage of it is not likely to have any other plan than to have the number stay always with the stand, the number on the hive changing whenever it changes from one stand

to another. I don't know of any better way than to have tags with numbers on them, so they can easily be changed from one hive to another. But I don't think celluloid is the thing. It is, I think, more expensive than tin, and not so durable. I spoiled some for Emma last winter by having it too near the stove, and I'm afraid the heat of the sun would sometimes be equally great. I think it would pay Mr. Hyde to have some tin tags painted, but I think you can get them up in quantity for less money, and accommodate a good many.

Marango, Ill.

C. C. MILLER.

[We can certainly make the numbered tin or zinc tags—numbering black and tags white, if desired. Perhaps another year we shall list them.—Ed.]

CONDITIONS FAVORABLE FOR SWARMING.

From the 3d to the 10th of June I had 14 swarms from 100 hives of bees. From the 11th to the 29th inclusive I had 7 more swarms. During the first period the bees gathered some honey; but during the second period they gathered it much faster. During the first period the days were hot; but during the second there were many hot days also. But—and here comes a difference—during the first period, not only were the days hot but the nights were unusually warm for any time of the year; while during the second period the nights were noticeably chilly. So my conclusion would be that hot nights with hot days, during a honey-flow, tend to produce what is called the swarming-fever; while cool nights—other conditions being the same—tend to discourage it. This in connection with your second editorial, page 488.

JOHN S. CALLBREATH.

Rock Rift, N. Y., July 1.

[Very likely you are correct. We had those conditions during the time referred to in the editorial.—Ed.]

THE CLOVERS VALUABLE TO BEE-KEEPERS, WHEN SOWN FOR BEE-PASTURAGE.

Mr. Root:—Will you please give a short article on crimson and alsike clover? I should like to know when to sow them, and also their value as bee-plants.

D. P. REAVIS.

Francisco, Ind., May 30.

[Alsike, medium red clover, and all the clovers commonly used in farming, are usually sown on grain in the spring. This whole matter is so well known that we need not take space for it here. Crimson clover is something new; and it has been clearly proven in many localities, even as far north as we are here in Ohio, that it may be sown, say at about the time corn is cultivated for the last time, in the corn, and will then take root, and come up and get sufficiently established to withstand the winter, blossoming some time in May, a little before white clover or any other clover comes out, if I am correct. During the coming fall this matter will be tested sufficiently to settle the question as to just how much crimson clover will do in furnishing feed, bee pasturage, or clover to plow under.—Ed.]

THE PROPER WEIGHT FOR BICYCLES; GEAR, TIRES, ETC.

Friend Root:—There are two questions I want to ask you that I am anxious to know. 1. What is the weight of the wheel that you use in your trips about the country? 2. What is the gear of your wheel, and what gear would you advise for all kinds of roads? Mrs. T., as well as myself, is an enthusiastic wheeler as well as bee-keeper, and we are no "spring chickens" either. Another thing, why doesn't somebody write a little book, to sell for about a dime, on the care of the wheel—how to repair it, adjust it, and fix the different makes of tires, etc.? In my opinion, A. I. Root would be the man. Had I had such a book at first it would have saved us a great deal of annoyance as well as some money.

M. F. TATMAN.

Rossville, Kan., July 3.

[If a person is an experienced rider—that is, has had at least one season's experience in riding, so that he feels measurably at home—a 22-lb. road wheel is about right. If he is a learner, a 25, 27, or 30 lb. wheel—perhaps the last weight—would be better for him. It is usually best for the beginner to purchase a second-hand wheel weighing about 30 lbs.; and these he can get very cheaply now, because the more experienced riders are now all crazy for the light ones. A. I. Root is now riding an 18-lb. Rambler, 1 $\frac{1}{2}$ racing tires, and geared to 68 inches. He weighs about 125 lbs., normally, but this wheel seems to be a little too light for him; for he has broken out several times some of the fine cobweb spokes, and has buckled his frame a little. The latter has not hurt its riding qualities, and the spokes have been replaced at slight expense. As a general thing, however, I think it would be better for the average experienced wheelman to ride something a little heavier—about 22 lbs. seems to be now about the accepted weight; and, if indications are correct, riding weights will not run much under this next year. The 22-lb. is what I am riding myself—a Monarch, which I prefer to a Rambler. I have not had the least trouble with it, and often carry my boy on the handle-bar in what is called a "Kozy" child's seat. Our combined weight is about 180 lbs.; and yet as I ride carefully ten or eleven miles an hour I have no fears but that my bicycle is amply strong. My machine, as well as my father's, is geared to 68 inches. This is none too high for a light-weight wheel such as 20 and 22 lbs. When wheels weighed 40 or 45 lbs., 56 and even 60 gear was high enough.

I see there is a good deal of effort made now to get a changeable gear—one that may, by a "flip of the fingers" at the saddle or handle-bars, be changed to a high or low gear. Possibly I may be mistaken, but I would not give a cent for any of them. With my 68 and 70 gears that I have tried, I think I have climbed all the hills that I ever did on my lower gears. Early last year I rode a Victor with 63 gear, climbed all the hills with it, and later in the season I put on 70 gear and rode up the same hills. The point is right here: With the higher gears the rider has more time to push the pedal down. With lower gears he has to keep chasing the pedal. Under such circumstances, especially in high speeds, it is not possible to exert the full amount of power on the pedal. Both theoretically and practically, then, I prefer a gear not lower than 68. But I would add a proviso that the wheel should not weigh more

than 30 lbs. I have not tried a 76 or 80 gear, but I should not be surprised if I should find comfort in using them also, because there is less kicking in the air, no chasing of pedals, but a slow, easy, graceful motion, instead of a wabbling, quick-kicking, pedal-chasing, so characteristic of the lower gears.

Although you do not ask it, perhaps a word in regard to tires may not come amiss. I prefer a single-tube semi-roadster—that is, without removable inner tube. They hold air better, and it is now possible to repair them. A couple of years ago we did not know how; but now that that question is solved, single-tube tires, in my estimation, are far preferable.

As to size of tire, while I once, with all the rest, thought 1 $\frac{1}{2}$ and 2 inches were the most comfortable for the road, the 1 $\frac{1}{2}$ semi-roadsters that I ride are just as comfortable; and instead of weighing 6 or 7 lbs. per pair, they register only 3 lbs. A. I. R. is riding a 1 $\frac{1}{2}$ double tube; and while he is not particular whether it be single or double, he says 1 $\frac{1}{2}$ is plenty large for him.

You suggest the wisdom of writing a little book; but so rapid has been the change in the subject of cycling, such a book would be out of date in six months; and so we must turn to the manufacturer's catalogs, and to the special journals that are issued. The *Bicycling World*, published at Boston, Mass., is one of the very best. The price is \$1.00 a year, weekly.

There, you can see that bicycling is one of my hobbies. It is almost impossible for me to stop here. But I remember that I am talking to bee-keepers mainly and wheelmen secondarily, and so I will stop right here.—Ed.]

W. D., Ky.—To get rid of the small ants, find their nest if possible. Make a hole through the center of the nest with a crowbar, and pour in about half an ounce of bisulphide of carbon, which you can get at your drugstore. Quickly cover the hole, and it will destroy the nest, ants and all, but it will not kill vegetation. If you can not find the nest, put a little molasses on a board, poisoned with strychnine, or some other poison. Put this in a place where only the ants themselves can get at the sweet. This will kill them as they make their visits; but, of course, the better way is to get at their nests.

G. L. V., Mass.—The subject of artificial incubation of queen-cells is very old. Under the heading of "Lamp Nursery," in the old editions of our A B C book, away back in 1878 and '9, there are full particulars on this subject; but there are very few queen-breeders, if any, who now use artificial heat for hatching cells. What are known as hatchers—a series of queen-cages put down between the frames, or on top of them, over a powerful colony—is preferred. These little cages contain a single cell; and the heat arising from the cluster is sufficient to hatch them. Of course, the natural heat of the colony is far superior, more regular, and better in every way, than any thing that can be supplied by artificial means.

DR. MILLER's slang—just see how he goes for the editor, in Straws! and then observe how he sins himself in the same way, in the next few Straws!

PERHAPS it is a little early, but not very much honey, even from basswood, is being reported. We have had a fairly good flow, and hope others have fared as well as we.

You will see by Straws that Dr. Miller thinks the hive discussion should be continued as long as it brings out valuable facts as it now seems to be doing. I really do not wish to continue the subject if there is not a call for it, and simply ask. Do others feel about it as Dr. Miller does? GLEANINGS is yours, and ready, I hope, to dish up for you whatever you like best, providing it is good and wholesome.

SHALL the Bee-keepers' Union be consolidated with the North American? is a question that is now and should be thoroughly discussed preparatory to the next meeting of the latter at Toronto. It is being advocated by the *American Bee Journal* and the *Bee-keepers' Review*. So far as I can at present see, GLEANINGS is also in favor of the scheme. Bro. York thinks it would give us a membership of 500 or 1000, and a fund from both treasuries of \$800; and then, as he pertinently remarks, "we could petition Congress or State legislatures, in such a way that they would hear and—grant." You are quite right, Bro. York. Of course, the consolidation would not affect the workings of the Union.

WE have printed some 52,000 copies of the A B C book heretofore, without a scrap of advertising. In the present edition, or the one about to be launched forth, we propose to break over our rule and allow a certain amount of select advertising from queen-breeders, supply-dealers, honey-merchants, and, in fact, anybody reliable, desiring space at the end of the book. The A B C goes to a very desirable class of customers—beginners—who would see the advertising cards on its pages when they might not see them elsewhere. The space will be charged for at the same rate as for one insertion in GLEANINGS. Copy must be sent in before August 1, when the forms will be closed. The next edition comprises 10,000 copies. A few copies have been sent out to supply pressing and immediate orders.

BEE-PARALYSIS INHERITED FROM THE QUEEN; DUTY OF QUEEN-BREEDERS, AGAIN.

A CORRESPONDENT writes that he purchased a queen last year of a queen-breeder, and that

the bees of this queen subsequently developed bee-paralysis. In the mean time he had raised nine queens from this mother, and the bees of all these nine queens showed the same disease. This, I firmly believe, is only one of many cases, and goes to show that the disease is inherited from the queen. How careful, then, all queen-breeders should be that bee-paralysis is entirely exterminated from their yards! Some of the friends thought that my calling for a "show of hands" of all queen-breeders who would destroy every case of paralysis in their yards, as soon as discovered, was a measure both extreme and unnecessary. It may be in the case of those who do not sell queens; but it certainly is not for the breeder.

THE HOME OF THE HONEY-BEES ENLARGED AGAIN.

ONCE more the Home of the Honey-bees is to receive a substantial enlargement in order to enable it to turn out more goods. Another story is being added to our wood-working building, and new machinery is being put in, so we hope to nearly double our present capacity for turning out hives and sections. We have already ordered another large engine, which all told will give us a total horsepower of about 200. New and larger exhaust dust-fans and dust-separators have been found necessary in order to keep pace with the unprecedented demand for our new polished and sanded sections. Later on we will show you how we look with the recent additions.

DEATH OF A PROMINENT SUPPLY-MAN.

I REGRET to chronicle the death of Chas. E. Parks, which took place at his home in Watertown, Wis., on the morning of July 1. He was a member of the firm of the G. B. Lewis Co., of that place. He was intelligent, progressive, and, with his other accomplishments of push and business sagacity, an inventor. He was, I believe, the largest stockholder in the company, and the man who invented the machinery now in use by that firm, for making sections, and also for what is known as the Parks basket-crate—a sort of shipping-basket or box that is used largely for a great variety of purposes. It was he also who demonstrated, if I am correct, the possibility of making the present one-piece sections in quantities. Although not the original inventor, he brought the section before the public. Mr. Parks was personally known to the writer, who has had several pleasant talks with him at conventions and elsewhere. When I last saw him he looked the very picture of health and strength; and it was a great surprise to me when I learned a few months ago that he was lying dangerously ill in Florida—notice of which I gave at the time in these pages. He leaves a wife (daughter of G. B. Lewis) and three children.

The affairs of the G. B. Lewis Co. will be con-

tinued as formerly, and will be managed, probably, by G. B. Lewis and his sons.

CRIMSON CLOVER AS A HONEY-PLANT.

□ WE clip the following from a recent issue of the *Farm and Fireside*:

Crimson clover, sown the middle of August on the writer's experiment plot, commenced blooming the first of May and ripened its seed early in June. For four weeks the honey-bees hummed joyously over its beautiful blossoms. Wherever it can be grown, crimson clover is a honey-plant of great value. It is the first of all the clovers to bloom. Where the bee-keeper has white clover or alsike clover, he can add one month, at least, to the length of the honey harvest by a field of crimson clover.

I could not make out from the paper either date or locality; but the paper is published at Springfield, O.

NUMBER-TAGS FOR HIVES.

IN another column Dr. Miller inquires regarding the cost of tin tags, numbered, to put on hives. In our last issue this form of tag seemed perhaps the most feasible; but since that time I have called to mind how queen-nursery cards, of which we used to sell a good many (a card of ordinary cardboard manilla, having certain printed matter on its face), have stood the test of year after year of weather; and I have been wondering if a tag-board manilla would not be far better—or at least as good, and far cheaper. We know that paint does not stick readily to tin. In four or five years it will either rub or flake off, and the tin will turn to a dead, rusty brown, leaving the figures in black in poor and indistinct contrast. Manilla tags, something like what are used on express packages, when neatly tacked upon the hive, and printed with a bold-faced type, with common printers' ink, will stand the weather, and outlast the painted tin tags. □ It is possible that it might be advisable to treat such tags, after being printed, to a solution of oil, but I hardly think it necessary. Well, such tags can be gotten up for one-fourth or even a fifth of what ordinary tin tags would cost; they would last as long, or longer, and could be easily duplicated, when necessary, at a slight cost.

GLEANINGS UNPREJUDICED.

IF there is any one thing that the editor of GLEANINGS is trying to do, especially since, as publishers, we are interested in a large supply business, it is to select fairly, impartially, and honestly, matter that shall give an unprejudiced view of bee-keeping. It is easy and natural for a trade-journal to be prejudiced toward its own business; and while, perhaps, we may possibly have been *unconsciously* guilty in this respect, we strive earnestly to give every side a fair hearing. The whole bee-keeping world seems to have settled down, in the United States at least, on the idea that the

Langstroth hive is about right; but here come along some very prominent, influential, and expert bee-keepers, giving some solid arguments in favor of a deeper or cubical hive. It is with pleasure that I give you the benefit of their opinions in this issue. Should these opinions prevail, and carry that bee-keeping world with them, it would make a howl among supply-dealers. While we might "howl" with the rest, we propose to let the truth come out.

Again, I have tried to, and propose to let the advocates of the double brood-chamber give their honest opinions concerning the merit of that form of hive. And, still again, I propose to let the ten and twelve frame folks advocate *their* ideas. While I do not think it would be wise to continue this discussion indefinitely, enough has been said to call out more, and to lead us nearer to the goal that we are all seeking—the kind and shape of hive that will give us the most honey or money with a minimum of labor.

FOUL-BROOD INFECTION FROM COMBS; AN AGGRAVATING CASE.

A PROMINENT bee-keeper, whose name I do not mention for fear he would not desire to have the facts made public, writes that one of his out-yards is badly affected with foul brood. It seems he purchased some combs of a party who lived at some distance. These combs were shipped in open hive-bodies, with only slats nailed over the top. They arrived at the station on Saturday night, and unfortunately the out-yard in question of our friend was within a short distance of the freight-house. Of course, it was not bee-proof, and a window was broken out. Our friend being entirely ignorant of their arrival, the bees on Sunday had a regular "pow-wow" over those combs, because they were dripping with honey; and the agent, arriving, threw the freight-house doors wide open to "let the bees out." Of course, this made matters ten times worse. He sent notice to the owner of the out-yard, but it seems he did not receive it—or, at least, not until the next Monday morning, when all the mischief had been done. At that time he repaired hastily to the scene, examined the combs, and found them to be badly affected with foul brood. Well, in just three weeks' time the disease manifested itself in various quarters of the apiary, just as we should expect it to do. Our friend managed to keep it down somewhat by cutting out diseased cells as fast as they appeared, as he did not wish to resort to the heroic treatment of destroying all combs, brood and all, until after the harvest. This procedure, it seems, kept the disease under control, but it kept breaking out elsewhere. His plan is now to put all the diseased colonies in an isolated location, and prune the diseased brood out, or destroy entirely the combs badly affected.

The combs which were shipped in open hive-bodies in the first place, and which gave rise to foul brood in an apiary that was perfectly healthy previously, should at least have been examined before being shipped. I will assume that the party who sent them was ignorant of the presence of foul brood in them; but, ignorant or not, it seems to me he should be prosecuted to the full extent of the law, to teach him a lesson; at all events, I think it would be wise for any one who buys combs to examine them carefully before using them. If they come from an apiary whose owner is slipshod in his methods I would not take them at any price, especially if foul brood had been in the vicinity, or was likely to be. It seems that the party who shipped the combs to our bee-keeping friend in the first place was warned to be very careful. In view of that warning, the fullest penalty of the law is none too good for him.

The bee-keeper having just acquired the disease in his out-apiary asks what we think of his methods of procedure—cutting out diseased spots in the combs; of entirely destroying such as were badly affected; and finally of isolating all cases so treated, in a location by themselves. The plan is all right; but to be on the safe side I would see that all such honey, and, in fact, any of the honey coming from that yard, even though the colonies from which it was taken appear to be perfectly healthy, be boiled, or at least be kept at a temperature of 180 degrees for two or three hours. We always want, for safety's sake, to assume that the honey that has been extracted from colonies in the vicinity of foul brood may contain the germs of the disease. If it is put on sale at the market there is quite a liability that bees in the vicinity will get a few sips at it, and then away goes the contagion in a new locality.

With regard to cutting out diseased spots from the combs containing here and there a little infection, this may be all right as a temporary expedient; but I have rather the impression, from reports received, that the disease is quite liable to reappear in such colonies. I see no reason why it should not. To make a sure thing of 'it, I think putting the bees into clean hives, or one that has been thoroughly boiled, on frames of foundation, and compelling them to draw some of the foundation out before feeding, is the only real safe way. If there are only two or three colonies in the yard so affected, they should be all so treated; but when the disease gets such a fearful headway, and honey is coming in, perhaps the temporary expedient of cutting out the diseased spots would do during the honey-flow; and after that time I would certainly extract all the honey after the brood-rearing had ceased, or largely so; give them frames of foundation, and feed the honey back; or, better yet, after it has been boiled; or, better yet, clean syrup. I am not

satisfied that medicating it with any sort of drug is an advantage or may be.

THE FIVE-BANDED BEES.

DEDICATED TO DR. MILLER

By J. H. Markley.

(Lib.—Branigan's Pup.)

Old Mr. Doolittle had some fine bees,
A cross from the very best strains;
For seventeen years he had bred them with care,
And spared neither money nor pains.
They had the least bit of a stump for a sting,
And yet had a very long tongue;
Large bodies, strong legs, and very large wings,
They went to the field very young.

Chorus after each verse:

Buzz-a-buzz-buzz what wonderful bees!
For beauty they surely would please,
There never was known such workers before,
As Doolittle's five-banded bees.

They worked on red clover with perfect success;
Were busy from morning till night;
They made lots of surplus when other bees
starved;
Their debut was hailed with delight.
Their queens were prolific—remarkably so—
Laid eggs with wonderful haste;
For beauty no other queens could excel—
Wore five bands of gold round their waist.

Chorus:

They found their way to the Home of the Bees,
To show that they were just the thing;
When Ernest got after them with a sharp stick—
He said, "The five-banders will sting."
He said that, as workers, they didn't excel;
Their "gold plate" was not worth a pin,
They winter-killed worse than the "leather-
backed" strains;
Now, wasn't that truly a sin.

Chorus:

Bee-keepers turned over to Ernest one day,
And each of some point would complain;
And thus did the people with wonderful thud
Sit down on the five-banded strain.
Some said they were lazy; some said they were
cross,
And some e'en their beauty decried,
They died off in winter, they dwindled in spring,
And thus the poor five-banders died!

Chorus:—

Carbondale, Kan.

[I am sorry I can't rhyme in my answer to you; but my "sharp stick," I think, never got after Doolittle's five-banders. His strains (and I saw them in his own yard) were not cross. They appeared to be good breeders; and that they were good workers I had no reason to doubt. I did not criticise Doolittle's strain or that of any one else who bred them carefully from *purely Italian stock*; but the *tendency* of some who turn their sole attention to *color*. A strictly five-banded colony is rare, and hard to get, even if we eliminate all other desirable qualities out of account; and in order to fill orders according to color and marking, every thing else was apt to be lost sight of. The mere fact that reports from all quarters showed that the craze for color was giving us bees cross and short-lived (that is, poor winterers), shows that there was good ground for my protest. I do not object to color if we do not sacrifice other qualities that go to make up the bread-and-butter side of bee-keeping.—ED.]

OUR HOMES.

Know ye not that ye are the temple of God, and that the Spirit of God dwelleth in you?—I. Cor. 3:16.

Saturday morning, June 29, news reached me that a near and dear relative was very low with malarial typhoid fever. As her home was not over forty miles away I started off on my wheel. When a little more than half way there I stopped with another relative, a brother of the sick one; and in talking the matter over in regard to these fevers that are so apt to occur at this season of the year, my attention was turned to a matter of vital importance to the homes of our people—the water we drink. Let me go back a little.

Forty years ago our nearest neighbor in the town of Mogadore, Summit Co., O., lost a child by typhoid fever. My mother went over and helped to take care of the child. Shortly after its death she was taken down and had a long siege; in fact, she just escaped with her life. Before she recovered, a sister, very near my own age, was also stricken down; but the physicians, with great care and labor, managed to prevent the malady from going any further. It was then nearly springtime. The first case of the fever started in July or August, and it ran in that neighborhood for more than half a year after. Well, my uncle told me there was typhoid fever in that neighborhood now; and the Mogadore physician said they had typhoid malarial fevers in that locality almost every year. A year or two ago he became convinced that the water they drank from a certain spring was at the bottom of the trouble; and he gave strict orders that no water should be used for drinking—purposes from that particular spring. Some friends came from a distance to take care of one of the patients; but the doctor told them the same—they must not drink any water from that spring. Well, all of the family and all of the neighborhood obeyed the doctor's commands except one young woman who laughed at his caution, and said she would drink all the spring water she pleased. She alone was stricken down with typhoid fever. Those who heeded the doctor's orders escaped. This spring is right close to what was my boyhood home. I have drank from it hundreds of times, and know all about it. It is at the foot of a hill on the edge of a mucky swamp. The water boils up from the sandy bottom. If you dip out a painful, however, before the spring is full again, surface water from the mucky swamp may run in, as well as spring water from the bottom. Not more than two rods from the spring there used to be an old stable; a little further away, a slaughter-house. Is it any thing strange that, when the spring should be dipped dry, may be several times a day—say on washing-day—that the surface-water from that nasty swamp should mix in with the pure water? And, by the way, typhoid malarial fevers almost always begin to appear when the wells are pretty nearly dry. The State of Michigan made some extensive experiments along this line some years ago, and gave us some carefully prepared statistics that seemed to indicate very plainly that low water in wells must have some connection with the prevalence of fevers in the locality. Well, after we had talked this matter over, and each one present had furnished more or less facts—facts all pointing in one direction—I began to ask questions in regard to the drinking-water, etc., where our relative was now prostrated with fever. I was told they had an excellent well of water; but, like many other wells at this season of the year, the water was very low. Furthermore, in building

an addition to their home a year or two ago, they built directly over the cistern; and the sleeping-room had been located in this new addition, almost *directly* over the cistern. I at once questioned about the state of the water in the cistern. Being covered up so closely it smelled very bad; and our sick relative had said, just before she was taken sick, that she was going to have that cistern cleaned out and filled up, and a new one made out in the open air. I stepped on my wheel, and in a little more than an hour I was at the bedside of my friend and relative. While attending school in early life my home had been with this aunt; and a strong friendship had always existed between us, especially after I decided to make her God my God, and her people my people.

I found the doctor with many of my relatives consulting as to what could be done for the loved one. Their old family physician was absent on a visit, and a young doctor was called in from a neighboring town. I told him I wanted to meddle a little. When I explained that it was about the cistern and the drinking-water, he said I was exactly the man he wanted to find. The case had puzzled him ever since he took it up. In the early stages my aunt was delirious. She would get up in the night, before they knew she was very sick, and she was once found on the floor, in a faint. Unless constantly watched she would get up, and insist that she was not sick at all, and that the watchers and doctor could go home. He said he felt sure there was a reason for the peculiar symptoms of both members of the household. Some of the cistern water was pumped. None of it had been used for drinking—purposes, but it was too bad to wash even one's hands and face with. Furthermore, this cistern had at different times overflowed and got into an unused cellar; and this unused cellar was shut up close. Now, their well, where all their drinking-water came from, was not *twenty feet away*, in a porous, sandy, and gravelly soil, from this closed-up cistern and cellar. The patient was calling often for a drink of cold water right from the well. My uncle urged that there could be nothing the matter with the well water, because it was so beautiful to look at, and so pure to taste. When I told him the germs of fever might exist when neither taste nor smell nor *looks* would indicate it, he became greatly surprised. The doctor backed me up most vehemently, and said something as follows:

"Dear friends, the latest developments in the way of typhoid fever indicate most clearly that it is not contagious unless one drinks the water the sick ones have been in the habit of drinking."

Somebody suggested that there might be danger in using it for cooking.

"No, my friends," continued the doctor, "providing the water used for cooking be boiled, it seems to be perfectly safe. And rather than run any risk, if you have any reason to suspect the drinking-water, it should be boiled before using it. We are making great progress in this very matter of the cause of fevers, and the whole evidence seems just now to point to an astonishing degree, toward the fact that the water we drink—especially the cold water right from the wells or cisterns, is the main cause of these terrible fevers."

Now, friends, it did me a lot of good to have a good talk with that bright young doctor. He was full of life and energy, and full of love for humanity; and he assured me that one of the great obstacles in the way of getting rid of these malarial fevers was to get people to have faith in the doctor, and to believe he *knows* his own business.

So much for looking out for the bodily comfort and safety of my sick relative. At the time of my visit she had regained consciousness, and the doctor said the symptoms had changed unexpectedly for the better. She knew me, and expressed much pleasure in seeing her "boy" once more, for I used to be "her boy" in my schooldays. She expressed some surprise to see so many relatives coming, and, stranger still, because she was not, as she said, very sick. As it was evidently a task for her to hold on to any thread of thought for any length of time, I talked with her briefly at intervals. I very soon found out that death had no terrors for her, for her hope was in Him who has passed *through* death, that he might lead us and take us safely through the dark valley to the immortal shore beyond. I sang to her a verse of that old hymn—

How sweet the name of Jesus sounds
In a believer's ear!
It soothes his sorrows, heals his wounds,
And drives away his fear.

Then I talked to her about the helplessness of doctors and friends, but of the mighty power of the great Father who has promised to be with us in times like that. Fearing that she was becoming wearied I made some haste to bid her good-by, promising to pray for her. Before I had mounted my wheel again, *another* sister came to tell me what my aunt had said after I had gone out. It was something like this:

"Were you here when we had that sweet little meeting?"

When the listener assented, she replied:

"Oh, it did me so much good!"

I felt almost sorry I had not talked with her longer; but the doctor said, and I too felt sure, that her recovery depended greatly upon quiet and rest. He said he feared a return of her delirium; and any little excitement, especially any undue exertion of the brain, might prove fatal. Now, the particular point in this talk to-day, dear friends, is this: The season of the year is upon us when we may expect fevers. The condition of the rainfall where most of you live is such that your wells may be low. For the sake of your dear ones, for humanity's sake, and I think I may say for Christ's sake, do be careful, and look to it in regard to your drinking-water. If I am correct, people many times suffer greatly from the effects of bad drinking-water, even if they do not come down with a fever. The tired and overworked mother, the weary hands from the harvest-field, and, in fact, any and all of the inmates of our homes, may have headaches, a feverish feeling, exhaustion, and nervousness, to contend with that they need *not* have at all were these matters duly attended to. For a long time I have disliked the taste of the water from our cistern, even though we have a slate roof, and the best cistern we know how to make, with a filter for the water to run through. A few weeks ago we pulled out the chain pump and wooden tubing. This old wooden tubing was water-soaked and partly rotten; and just as soon as it was out of the way, that objectionable taste disappeared. We now have a water-drawer that takes air clear to the bottom of the cistern every time the pump is worked. If you have any reason to fear the water is not just right, and that you can not get water from any other source conveniently, boil the water before any of you drink a drop of it. I have not space here at this time to speak about the water furnished to the cows that give the milk; but I will just add that, in a neighboring county, a number of cases of diphtheria were traced almost unmistakably to the visits of the milkman; and our health officers are now demanding that he who sells milk shall furnish just as

good water for his cows to drink as he would furnish for his own family.

I felt as if it would be best for me to make my stay a brief one, and so I took my wheel again. May be the work I had done made me feel happy; and perhaps being free from care, and riding through a beautiful part of the country, also made me feel happy. And, by the way, it seems to me I never before saw so many pretty gardens as I passed that afternoon through Summit and Portage Counties. The gravelly hills especially seemed to be recognized and appropriated. Fruit and berries were plentiful everywhere. Why, in one place I saw potato-tops higher than the picket fence, and in the month of June too, and after that terrible frost just back in the month of May. Now, lest you accuse me of telling great yarns right here in one of my spiritual talks I will explain that the gravelly hillside where those potatoes grew had been cut into along the road, so the picket fence was on lower ground than where the potatoes grew. Yes, and people were digging new potatoes almost if not quite the size of hens' eggs. When I asked if it were possible that they grew after the frost, I was told they hoed the dirt over the tops and covered them up till the blizzard passed by. This was some trouble, but it gave them new potatoes of their own growing when they were retailing at 40 cts. a peck at the corner grocery. Why, it paid, and paid big, for all the time and trouble. But I must remember my gardening talks come in another department. For some reason, as I was telling you, a wonderful thrill of peace and happiness and joy came into my heart during my ride about sundown from Randolph to Springfield. The road was sandy, and made the wheeling difficult; yet by going along the foot-paths that had been trodden by the bare-footed children I made very good speed. In one of these foot-paths that ran up over the bank quite a little higher than the road, my pedal struck the hard ground at the side of the path, and I went over down the bank almost as suddenly and unexpectedly as if somebody had hit me with a club. I was a little bruised, it is true, and my clothes were somewhat soiled; but almost before the bruised spots had got done hurting I burst out into expressions of thanksgiving and praise that I had been hurt no worse, and that it was my privilege to live in such a beautiful world, and to visit so many pleasant and happy homes. Yes, and may be I could help a little to make them pleasanter and happier still—who knows?

As my home was nearly 30 miles away, and it was between sunset and dark, I decided to pass the Sabbath *away* from home.

Next morning at the usual time I was sitting in the same old Methodist church where I used to attend Sunday-school just 45 years before. The superintendent was absent, and the minister was away, so they called on me to give them a little talk at the close of the exercises. I told the children who I was, and pointed out to them the seat where I used to sit when I was only ten years old. Then I told them of one particular Sabbath when I repeated *forty* verses from the Testament, and how one of my classmates cried because the teacher told him there was not time for him to say his *eighty* verses. You see, they had just started a new plan. For every ten verses we got a blue ticket; for every ten blue tickets we had a reward-ticket; and for every ten reward-tickets we were to have a little book. I think the little book I got for committing to memory 1000 verses is somewhere in the family now. I told that little Sunday-school I would not repeat *all* of those forty verses then and there that I committed to memory 45 years before; but I

said I would give them two or three verses that I verily believe had lodged in my memory away back in earlier years, and have held their place there ever since. In fact, I do not know but they are framed and hung in that little picture-gallery I told you about in our last issue; and, oh what nice little verses they are to be engraved on the tablet of the heart—especially little hearts!

"But I say unto you which hear, Love your enemies; do good to them that hate you; bless them that curse you, and pray for them which despitefully use you.

After Sunday-school was out we drove around past that spring that had been the cause of so many cases of typhoid fever. It was walled up, and there did not seem to be any outlet to it—at least, not a very complete one. And this suggests an important matter. A spring or well, to be wholesome, should have some method of letting the water run away in a continuous stream, or of removing the water daily. The stream down by Champion Brook runs a steady stream except during a very severe drouth. Just as soon as it stops flowing over the top of the iron pipe which surrounds it, the water becomes stagnant, and unfit for drinking. Last season, when the boys told me they could not drink the water, I made an opening in the iron pipe, a foot lower down. Then it began to flow as before, and the water was cool and nice. Of course, we can not have a running stream from a well; but most wells furnish very much better water if there is a constant removal of the water. Sometimes watering the horses or other farm stock will very much improve the drinking-water of a well, especially where the water comes out of a rock. But the greatest care should be taken to prevent surface-water from seeping in during a dry time. Large-sized sewer-pipe set down into the rock, the joints made water-tight by cement, is perhaps the nicest arrangement that can be made; but I believe that, taking the wells as we find them, water from a good cistern, with slate roof on the buildings, is very much safer as a preventive of fevers.

In the afternoon I attended a funeral. The deceased was a prominent man in the vicinity, and I met great numbers of my old friends—many of them whom I had not seen for between forty and fifty years. Now, I do not know that I ever enjoy attending a funeral; but I did feel very happy at that funeral that Sunday afternoon. Although the house was crowded, I found a place near an open window where I could hear distinctly every word uttered by the gray-headed clergyman. Most of the friends of my boyhood had grown gray-headed during the lapse of time, and many wrinkles furrowed the faces of those who were boys and girls in my schooldays; but, notwithstanding, they were good-looking still, for they were for the most part progressive, intelligent people. Now, friends, if we live right, if we take care of these bodies right, we may be happy on Sunday, and we may be happy week days. We may be happy when we are old and gray and wrinkled; yes, we may be happy and joyous, even when we attend a funeral. By the way, I want to speak of the hymns that were sung. It seems to me I never heard any grander sacred music than we had there. There was one deep bass voice that had a depth of volume, and softness and flexibility (if our musical friends will not criticise my expressions), that stirred wonderfully the emotional part of my nature. I asked somebody, after the service was over, who it was.

"Why, that was Captain Clemmer."

"John Clemmer?"

"Yes," was the reply, "John Clemmer."

"Why," said I, "he was a celebrated singer fifty years ago."

And it is true. When he was twenty he could sing so as to move the hearts of men; and now at seventy he had this wonderful gift still; and may God grant that he is still using this gift as a power to bring men out of despondency and darkness into the bright light of faith and hope in Christ Jesus.

IRRIGATING FORTY ACRES OF CELERY.

Next morning, after the events narrated above, I was up and dressed and on my wheel at 15 minutes past 3. May be some of you do not know that it is light enough to see, the first day of July, at such an early hour; but so I found it. I begged permission of my relatives to get up in this way without disturbing any of them. My ride was along near Springfield Lake, in Summit Co. The valleys between those great gravelly hills were so full of fog that they also looked like lakes. At just 5 o'clock I rode into the beautiful city of Akron. It was not quite breakfast time, to be sure; but I was quite ready for breakfast. I asked the night policeman if he could tell me where to find a lunch at that early hour. He said at first it was somewhat of a question; then he suddenly remarked: "Oh, yes! there is a man and his wife over there who are *always* up and ready for business. I feel pretty sure they will fix you out nicely." In a minute more, with the aid of my wheel over the vitrified-brick pavement, I stood before a little building called a temperance restaurant. The man was up, and said I could have some breakfast in five or ten minutes. His face looked familiar to me; and when I told him who I was, it turned out to be one whom I met years ago in our county jail. He was in trouble; and, together with the other spiritual advice I gave him, was—what do you think, dear reader? Why, I told him the shortest way out of *his* troubles—in short, the "straight and narrow path" to get out and keep out—was to *get married*. He knelt with me on the cold stone floor of the jail, and promised to lead a better life; and he finally, it seems, took my advice and got married; and he and his wife had been for years doing a good business right on that crossing close by the electric cars and steam-cars. They gave me a breakfast in short meter, that was fit for a king—or, rather, I *thought* it was, and that, you know, amounts to the same thing.

It is a little funny that, when I got on my wheel, I was happy again; yes, a new streak of happiness seemed to have got into my wheel; and there is not any nicer road for wheeling, that I know of in the world, than that from South Akron to Copley.

I reached friend Atwood's celery-farm before he was up—or, at least, he was not out to his place of business. I found a boy firing up a traction engine. This engine was belted to a rotary steam-pump. The pump was large enough to throw a stream of water four inches in diameter. The inlet-pipe is five inches, and the outlet four. This rotary pump lifts the water perhaps five feet. He has utilized a creek that runs perhaps a quarter of a mile north of his forty acres of celery. The water comes to the pump through a twelve-inch sewer-pipe. Then by cementing the joints very securely he sends the water through five-inch

sewer-pipes all over his forty acres. The four-inch stream pours out on, say, half an acre at a time. When this half-acre is thoroughly soaked he puts it on the next one, and so on. Whenever the ground gets dry enough the cultivators are kept going, and the whole thing is working like a charm. His five-inch sewer-pipes, good quality of seconds, cost him only a cent and a half a foot. He manages to dispense with expensive valves by plugging the openings with a wooden plug held in place by bolts on a U-shaped yoke. In fact, our friend Atwood has, at comparatively small expense, worked out and got into actual practice the best irrigating-plant I ever saw anywhere.

Now a little advice to those who are thinking about irrigating. A windmill may answer for small areas—say a quarter or half an acre; but for a whole acre you will want a big windmill and a big tank for storage. But you want lots of water to do the work right. During a severe drouth, such as we had in May, sprinkling water on top of mucky ground is apt to do harm rather than good; and even letting water on through an inch hose is slow work, and answers for only a small area; but with a stream coming out of a four-inch pipe you can flood the ground, and make it soak in clear to the roots of the plants. The forty acres of muck land I have mentioned has a very little slope, so that, by taking water on at the highest point, it can be made to run over the whole surface. I should have said, looking at the ground at the time I was there, it was almost too wet. Friend Atwood says it is the way celery wants to be kept to do its level best. As one approaches the grounds and gets a glimpse of it from the hill, it looks almost like an enchanted land instead of a reality. The straight rows,* running away off in the distance, look like slender threads of gold, especially where the Golden Self-blanching is planted. Then the White Plume would make silver threads, contrasting beautifully with the other; and the Giant Pascal with its deep dark green, and larger, and of more robust growth, comes in again to delight the eye and please the lover of high-pressure gardening. Friend Atwood has been constantly increasing his acreage ever since he started, and his celery has always gone off at good prices; and, if I am correct, the supply has never been equal to the demand, especially during the winter months. At present they have found the safest method of wintering to be the open air. With their great quantities of muck that can easily be kept dry for facility in handling during the winter months; *i.e.*, it is kept dry by letting the water off through the drain-tiles—they get a complete protection from frost, and are never troubled with rot. This land, I presume, would not have brought \$5.00 an acre a few years ago; but now I doubt whether it could be bought for \$200 an acre.

FOURTH OF JULY, AND HIGH-PRESSURE GARDENING AND FARMING.

You may inquire what these have to do with

*To secure rows so absolutely straight, as they do on celery-farms, a small rope—say something like a clothes-line, or larger if you choose—is stretched from one end of the field to the other. Then a roller, heavy enough to make the ground smooth and solid, is run over the rope, and the plants are set in the print this rope makes in the ground. The hard rolled surface also makes a nice place to walk on while you are setting the plants. After the plants are set, flooding them with water makes a sure thing of an even stand. I believe that sometimes, when the weather is exceedingly hot, the plants are shaded by one-foot boards held up by a piece of drain tile at each end of the board and one in the middle. As these boards are used afterward for bleaching the celery, they are always near by, ready for use.

each other. Well, only this: I have for six months past been trying to get time to visit friend Terry, my cousin Wilbur Fenn, and some of the other progressive men in that direction; and when it was decided that we should stop all work on the Fourth, and "shut up shop," letting every one celebrate and enjoy himself after his own fashion, I decided to take mine with a wheel-ride; and I commenced celebrating about 3 o'clock on the afternoon of the 3d. You know I always take a new route where I can do so conveniently, so as to see more "homes" and meet with more adventures. So this time I got lost as usual, and did not find myself until I was unexpectedly in sight of friend Crawford's. Even though it was nearly sundown I stopped to take a look at his berries. I wished especially to see if the runnerless strawberry on friend Crawford's grounds was an ever-bearer, as mentioned on page 573. Sure enough, it had some berries on, but they were not as small as raspberries, after all, and the plants did not come from friend Goldsborough, but from a man by the name of Niman, in Texas. It had put out blossoms, and ripened fruit of fair size and good flavor since my previous visit. Their potato onions had, in consequence of the dry weather, ripened up and matured a small crop almost before July came in. The white-top onions were also going to be a failure, or pretty nearly so, so far as getting top sets of any size was concerned.

I reached friend Terry's just as it was getting dusk. His automatic watering-device I found close by the roadside, and there it was doing duty, sure enough. The water (regulated by a float) always stands just so high in the trough, no matter how many cattle go there to drink; and not a drop of water is wasted during this dry time. The water comes from a spring on higher ground, four or five rods away. His potatoes this year are the New Queen, Irish Daisy, and the Freeman, with a few other sorts for testing. The Freeman, although an early potato, is making a much better show than any of the others. I could not see a trace of blight; the stand was very perfect and even. The leaves were thrifty, and of a bright green. Although his clover was the best I had seen in either Medina, Summit, or Portage Counties, it was having a rather tough time of it.

The succession of dry seasons we have been having is doing much to encourage opening up the low mucky grounds throughout Ohio, and some important facts are coming to light. In the potato-field adjoining Terry's, a valuable fact shows clear out in the road to the passers-by. Half of the field was planted with potatoes raised on upland, and kept hard and firm by being buried on Terry's plan until the time of planting. The other half of the field was planted with potatoes not as good, grown on muck land. The muck seed gave ever so much the best stand, and the potatoes are now away ahead of the others. I believe it is generally considered that potatoes grown on low muck ground are not as good for table use; but I think I have heard before that they were just as good to plant, or even better. It is often claimed that potatoes for seed raised on some other farm or some other ground are better than those raised on the same piece of ground.

I found Walter Atwood (brother to the one who has the celery-farm) cultivating his garden. A row of tomatoes containing green fruit almost full size attracted my attention. "Surely these haven't grown to this stage since the frost?" He replied that they were carried safely through the frost by being covered with a double thickness of burlap. Where only a single thickness was used, the plants were more or less injured. Well, half the row showed

beautiful, smooth, handsome tomatoes. They were grown from a paper of Burpee's Matchless. The other half were crooked, twisted, ungainly things, hardly worth taking as a gift, even when ripe. These latter were grown from a paper of seed furnished by the United States seed department. Of course, they were a free gift; but on a single row of tomatoes it cost my relative a dollar or more for taking a paper of seeds as a gift instead of buying them from a responsible seedsman. The government seed-shop had labeled them Lorrilland; but they were certainly nothing like the Lorrilland, but the poorest and most worthless strain I think I ever saw in my life.

I found my cousin Wilbur Fenn with the ground all fitted, ready to plant about nine acres of potatoes. These were to be put in the 5th of July. When I inquired what condition his seed was in he took me to the cellar and showed me over 100 bushels of Monroe Seedlings, scarcely sprouted at all, and almost as hard and firm as when they were first put in. It was a surprise to me, as it was the 4th of July, and after the most severe hot dry weather we have had in any season, to find potatoes in such excellent order as this. Well, it is somewhat owing to his good cellar for the purpose, and somewhat owing to the fact that the potatoes are regularly shoveled over about once in two or three weeks. He has learned the trade of keeping potatoes in good order, and he does it every time. This is a part of his system of getting good crops from potatoes planted in July. Yes, and we must not forget that the late-grown potatoes are the only ones that could be kept hard and firm, like these. The cellar is pretty well down in a gravelly loam. Then the earth is banked up all around, clear up to the woodwork of the building. The windows are tight, and covered with carpeting, so as to exclude light, and also to exclude the summer heat from the outside. In fact, it was so cold down there on the 4th of July that it almost made me shiver. His neighbors and others keep saying, "Well, you hit it this time, but some time you will be caught out by an early frost—see if you don't." Well, he has been caught repeatedly by early frosts and freezes; but he gets his potatoes into that cellar, by some hook or crook, notwithstanding; and such late-grown potatoes are worth more in the spring, for table use, planting, or any thing else. All things considered, he finds the Monroe Seedling the best for his special system of any. Of course, he has other potatoes planted earlier; and we looked over a whole potato-field of Freemans, Six Weeks, Craig Seedling; and last, and probably looking best of all, Monroe Seedlings that were pretty nearly a foot high.

Then we adjourned to the berry-patch. I think I never saw so many nice raspberries on, say, a quarter of an acre of ground before in my life. They are the Hillborn. But his gravelly loam is specially adapted to small fruits, and almost all other kinds of fruit generally. In going to the house we passed the strawberries. He went over to Matthew Crawford's after he had pretty well sold out of plants. But friend C. said he could give him some good plants of the Barton, Beverly, and Beder Wood. All are imperfect except the latter. I made quite a fuss over the raspberries; but I uttered more exclamations of delight over that strawberry-patch on the 4th of July. The whole family had used all they wanted, and there happened to be more beautiful large berries, dead ripe, than even "Uncle Amos" could manage. Now, I do not know whether it was the varieties mentioned; that beautiful, gravelly loam where there had been a garden

for a good many years, or whether it was cousin Fenn's special treatment; and especially I can not understand why he should have great *perfect* strawberries so late in the season when everywhere else they are dried up and gone. I have noticed that friend Crawford gives the Beverly a big recommend; and perhaps the excellent varieties have something to do with it.

By the way, I must not forget to mention that, while I was at friend Terry's, I was treated to a generous dish of his inimitable Sterlings, and on the 4th of July too. You know I once decided to drop the Sterling; but that beautiful rich tart taste, when once tried never to be forgotten, made me decide that the one row of Sterlings that still remains on our grounds shall be kept there after all, as so many people prefer the Sterling for a late canning berry, and one that will stand the frost as well as or better than any thing else. On the way to the house a group of five bright interesting children claimed my attention.

"Now, Uncle Amos, you must come and see our garden before you go home."

Sure enough, there was the *children's* garden. It was not much larger than a dinner-table—perhaps the size of two dinner-tables. It contained two monstrous hills of potatoes. Of course, Wilbur Fenn's children would have potatoes in *their* garden. Then there was one row of peas ready to pick, and a sprinkling here and there of other vegetables. And then I told them about Huber's garden. He promised his Sunday-school teacher to plant five cents' worth of seeds, and give the crop to mission work. He was going to take a five-cent packet of radish seed; but I suggested he should go to our seed-woman and get an ounce for the five cents, as he did not have to pay any postage. After planting his bed full (the bed being about as large as a good big dinner-table) he had some seed left which I told him he might take back. He took back three cents' worth, and paid *two* for what he planted. In about 30 days he sold 29 bunches at 3 cts. per bunch, making 87 cts.; but it was on one of our highly fertilized plant-beds. With another five cents he bought half a dozen tomato-plants. They are trained up on the most approved plan, taught by our Ohio Experiment Station, and they are now loaded with green fruit. That reminds me that we put our first picking of tomatoes on the wagon to-day, July 8. They were from the Fordhook Early, planted in a deep bed so they could be covered with sashes during the May frosts. They are now trained on poultry-netting, and stand perhaps four feet high.

At Willis Fenn's (another cousin) I found him spending the Fourth getting his ground ready for seed corn. Hay is worth from \$20 to \$25 a ton, and it behooves a progressive farmer to save every bit of it if possible. His plan of "cultivating" potatoes just before they come up pleased me so much that I want to describe it here. He uses the same clod-crusher described in the Potato Book, page 181. See cut below.

Clod-crusher and Leveler, made of 4x4 Scantling.

It is simply six 4x4 hard-wood scantling, 8 feet long, put together with bolts, with the corners down. This is drawn over the field so as to mash lumps, level the ground, and scrape the very daylight out of every thing in the shape of weeds just starting. It leaves the gravelly loam almost as level as a brickyard; and when the potatoes come through they look remarkably pretty, and the ground is in just the right shape for the Breed weeder a little later.

In cultivating potatoes or any other crop during a dry time like the present, I believe it is considered on all hands that level culture gives the best results. Stirring the soil has a tendency to make the surface dry out faster, it is true; but notwithstanding this, a soft mellow surface resists drouth infinitely better than a hard solid crust; so we must stir the soil. But if, after having stirred the soil, you leave it in ridges or furrows—even small furrows—such as our 12 or 14 tooth cultivators leave—the drying-out process goes on more rapidly than if these little furrows were all brushed down level and smooth; and in order to do this, friend Terry has a strip of board fastened to the back end of his cultivators, the corners of the board rounded off, and the lower edge slightly rounding, so that the ground which is a little lower in the middle of the furrow curves slightly upward toward the top of the hills. This treatment, both in theory and practice, leaves the soil in the best condition to resist drouth, and to take advantage of the first shower. As soon as you have rain enough to leave a crust over the surface, the harrower with the board follower should go over it again.

I found Richard Fenn (*still* another cousin) harrowing his potatoes with an ordinary square-toothed harrow, the teeth being straight down instead of slanting. I asked him if that was not rather rough treatment for the little potato-plants; but he told me to look at them after he had gone over, and see how much they were injured. I had to give up that he was doing a splendid job of cultivating, with little or no injury to the potatoes. His field had been gone over with the clod-crusher, shown above, just before the potatoes were up.

Further on I visited Mr. Metlin. He married a bright black-eyed cousin, who used to be a playmate of my childhood. I tell you, friends, it is awful nice to have a good lot of cousins, especially on the Fourth of July. These people had gone away; but the old black-cherry trees where I used to help myself to their fruit, 45 years ago, were still furnishing their luscious treasures. A big broad ladder stood right in front of the door, reaching into the top of one of the great old trees. Before I took my wheel again I pinned a paper on the door, which read: "Cousin Amos called, and in your absence helped himself to the cherries. He extends many thanks." Then I paid a brief visit to my aunt Julia, who is now 91 years of age, and the only remaining one on earth of my father's family of eleven boys and girls.

When my wheel and I reached my own home, our people were just gathering around a Fourth-of-July supper on the lawn. And thus ended my Fourth.

FLORIDA TRAVELS.

The home of Irving Keck, of Bowling Green, was my next stopping-place. Friend K. selected his present location after quite a little examination over different portions of Florida. One thing that attracted him to Bowling Green was the beautiful soft water; and his good wife has hit it exactly in calling it "snow water." It is so clear and soft that it reminds one of melting snow in winter time when you want a nice drink of pure water. Another thing that took hold of him was the sight of real corn-

cribs filled with real corn. Perhaps there are few other places in Florida where farming is carried on to such an extent as to require a corn-crib; but before friend Keck got down to raising crops of corn he brought in tools for farming such as they use in Illinois and Iowa; and he tells me that, when he first started to plow with two horses, the neighbors came for miles around to see the new-fangled farming-tool. But it was not long before they caught on, and he sold several plows. But before one of his neighbors could make it work he had to go over and start up and get the thing going. The corn raised is, however, different from our corn here in the North; and it is put in the crib with the husk on, the husk protecting it from the weevil, which are very bad in that warm climate. The locality seems to be a pretty fair one for bee culture; but friend K. has so many other industries on hand—fruit-growing, gardening, general farming, a small mill for grinding corn, with an engine to run it, etc., that he does not give the bees very much attention of late.

Charles Stevenson, of Bowling Green, purchased a queen and one pound of bees of us in the month of June; and from this start, and nothing else, he increased to seven colonies, besides the original, in one season, and produced 112 lbs. of comb honey. The next season he secured 350 lbs. of comb honey from five colonies; and this product from a single queen and a pound of bees in June is perhaps the largest on record. A sad fact stares me in the face right here. When friend Stevenson got that first pound of bees and queen he was full of enthusiasm and energy and love for the wonderful new industry. Is it not a little sad to think that a mere novice, almost without experience, should sometimes produce larger results in the outset than he does when he gets to be a veteran in the business? Now, Dr. Miller must not feel hurt because of what I have said, and imagine that I have nobody in mind but himself. It is not so, doctor; but just now my impression is that some bee-keepers right around Bowling Green would complain that theirs is not a good locality.

Most of our readers have at different times experimented with a little vegetable called chufa, or earth-almond. Well, these are raised in immense quantities in Florida, for pigs. The pigs harvest the crop, and leave the ground in splendid condition for any future crop. I think these little nuts (for they taste like nuts) are fully as good as if not better than peanuts, and they can be grown with very little care or labor in almost any locality. I believe they have a permanent value on the market, but I have forgotten what it is.

A great many experiments are being made in the way of permanent pasture in Florida; but the weather is altogether too warm for most of the clovers and forage crops of the North. The cassava root is very valuable, both for food and for stock; but it can not be kept any way but in the ground. It must be dug almost as it is fed out. This is the plant that furnishes the tapioca of commerce; and it is such a simple matter to separate the tapioca from the root itself that each housewife can prepare it herself. The residue of the root, after taking out the starchy portion, makes most excellent puddings—at least, it does under Mrs. Keck's manipulation. The plant is propagated by cuttings, or, in fact, by chopping up the stalks at almost any stage of growth, if I am correct.

There is very much difference in the quality of the soil in Florida. If you want good land, select that with a heavy growth of pine-trees—large trees, and close together. Where the trees are few, and far apart, and small and

spindling at that, the land is not of much value—at least, for farming crops. At different places in Florida you find little patches of sand, of greater or less extent, where it seems that almost absolutely nothing will grow. These are called "sand soaks," or "chokes." There are some of them on friend Keck's land, and he has tried in vain to get any thing to grow on these spots, unless it is the wild cherry. This flourishes where nothing else will grow at all. Friend Keck has a queer theory about orange-trees. He says twelve good orange-trees on an acre of ground will bear more fruit than any larger number, after they once get established. If these twelve trees were equal in size to some of the trees I saw, it might be true.

Most of our older readers will remember the articles we used to get from Mrs. Mahala B. Chaddock. Well, one of her queer speeches was, that she wanted to go down to Florida and wrap tissue paper around oranges, and drive a mule team. Through the kindness of friend Keck it was my pleasure to ride after a "mule team" several days. In fact, he took me from Bowling Green to Avon Park and back, a distance of twenty miles, or rather more, considering the roundabout way we went. Our first call was on the National Peace River Phosphate Co. The phosphate is secured by a process called in California "hydraulic mining." The surface soil is removed until they reach the strata containing the phosphate nodules. These are granules, the size of shot up to that of a hickorynut—perhaps the most of them the size of a pea or bean. By means of a steam-pump, water is thrown with great pressure into the bank, or sides of the soil, crushing and crumbling down the sand and phosphate grains together. Then the same engine that carries the pump sucks or draws up the mud and water. This is elevated sufficiently so it can pass through a series of revolving cylinders, letting the mud, dirt, and sand run off into a pond or lake, while the valuable phosphate is saved. After the sediment settles in the lake, the water is used over and over again. The valuable phosphate is then loaded on to cars, and carried to the mill, where it is more thoroughly washed, and then dried and shipped where wanted, to different parts of the world. Later on I passed shiploads of this phosphate going to foreign countries. The composition is similar to that of bone or bone meal; and it contains so large a percentage of phosphorus that it is now to some extent separated and used for making matches. Its origin is largely a matter of speculation; but it seems likely that it comes from decaying bones and animal matter of fish and various reptiles, which have accumulated or washed up into beds.* In process of time the phosphate grows or accumulates in these nodules. It is a little strange that this exceedingly valuable product of Florida is used but very little by Florida farmers and gardeners, because it does not happen to be the chemical element needed for their soils. A little talk with the managers of the phosphate plant very soon convinced me that there was no imaginary value placed on the product. In fact, they know what they are doing, almost as well as does the miner of gold or silver. The output is sold according to the per cent of

phosphate it contains; and this is determined by accurate chemical assay. The managers are as much at home in the science of chemistry as bee-keepers are in discussing queens and hives; and it brought vividly to mind my researches in chemistry during my early years, while I discussed the matter with them. One of the men on the steamboat told me the phosphate industry of Florida amounted to 27 millions of dollars a year; but from some government reports that I have gone over hastily since my return home, I am inclined to think that somewhere about half that sum, or less, would be nearer right.

STRAWBERRY-PLANTS.

It is altogether too dry here in Medina to fill orders for strawberry-plants, unless it is very small orders, with plants taken from our beds kept wet by our sub-irrigation.

WANTED—FIGWORT SEED.

If you haven't got any, can't you gather some for us? We will pay you \$2.00 for a pound of fresh new seed; and now is the time to gather it if it is growing on your premises.

WANTED.

Samples of the new vineless sweet potato. As there has been a good deal of inquiry in regard to this, I wish some of the friends would mail me some samples, to try their cooking qualities; also tell us how low you can ship them by the barrel.

SCARLET GLOBE TURNIP SEED.

We have something over 100 lbs. of this seed, raised by one of our bee-keeping friends. We can offer it at the following prices: Ounce, 5 cts.; 4 lb., 10 cts.; 1 lb., 35 cts.; 2 or more lbs., 30 cts. per lb.; 5 lbs. or more, 25 cts. per lb. If wanted by mail, add 10 cts. per lb. for bag and postage. By consulting any of your seed-catalogs you will see the usual price is 50 or 60 cts. per lb., oftener 60.

SWEET CLOVER OR BOKHARA SEED FOR SOWING.

As none has been offered in response to our call in last issue, we are obliged to buy the hulled sweet clover, called Bokhara, of the New York seed-merchants. This is just as good, but it costs more than the ordinary sweet-clover seed furnished by bee-keepers. This is because the latter is usually sold and sown with the hulls on. Now, this is just as good for seed with the hulls on; in fact, some claim that it germinates better; but when you are buying it by the pound you do not get as many seeds as when the hulls are off; therefore the best prices we can make for the present, on hulled clover seed, generally called Bokhara, is 18 cts. per lb.; 5 lbs. at 16 cts.; 10 lbs. or over, at 15 cts. If wanted by mail, add 10 cts. per lb. for bag and postage. We can supply any quantity promptly at the figures given above. As soon as we get some of the new crop with the hulls on the prices will probably be the same as in our catalog.

CRIMSON-CLOVER SEED, HOME-GROWN AND FOREIGN-GROWN.

In answer to several who have asked if the seed we advertise is home-grown we quote from a letter received by one of our New York seed merchants:

"Our crimson-clover seed is all imported stock. There is very little, if any, American-grown seed in market; besides, we are selling and shipping carloads to the producing countries; so, even if you buy direct from Delaware, it is very doubtful whether you get Delaware seeds. We consider the imported seed better and cleaner than the domestic."

By another season, very likely there will be plenty of home-grown. With the excellent reports that come with the crops that have been already produc-

*Quite a quantity of bones are thrown out in the mining operations; but these are either thrown aside, or utilized in some other way. Sharks' teeth are also quite plentiful in phosphate beds. I carried a lot around in my pocket until they cut through the lining, and then I had to give them away. If you were to see one of them, and feel its serrated edges, you would not wonder so much how it is that a shark can bite off a man's leg at one snap of its jaws.

ed for the past two or three years, it seems a shame for the United States of America to be obliged to send across the ocean for this seed. And here is a field for bee-keepers to get a crop of honey and a valuable crop of seed, and feed for all kinds of stock, to say nothing about improving the land by having clover to plow under. For prices see last issue.

AMERICAN PEARL ONION-SETS.

The present state of the crop indicates that prices will not be less than 25 cts. a quart, \$1.50 a peck, or \$5.00 a bushel.

White Multiplier onions, 10 cts. per pint; 15 cts. a quart; \$1.00 a peck; \$3.50 a bushel.

Winter or Egyptian onion-sets, quart, 5 cts.; peck, 35 cts.; bushel, \$1.00. If wanted by mail, add 10 cts. per quart extra for postage and packing. All of the above will be ready to ship when this reaches you.

We have described the above three varieties of onions so frequently that we shall not go over it again here, except to say that all of them may be planted out now. For fuller particulars, see our seed and plant catalog, mailed free on application.

OTHER THINGS THAT MAY BE PLANTED THE MIDDLE OF JULY.

Kidney wax beans will give a crop for table use before frost; and with usual good luck a crop of seed also; the same with the Best of All green-podded wax beans. Either kind, qt., 20c; peck, \$1.25.

Beets for table use do nicely put out now; also early cabbages if you have the plants. Carrots and parsnips, as well as mangels, will produce half-sized roots, which are considered better, by many, for stock. Put them in rather thick.

Now is just the time to put out celery, if you can get the plants; but at present we are short of all kinds.

Corey's Extra Early and Ford's Early corn will also give roasting-ears, probably. All kinds of sweet corn can be put in now for corn-fodder. Until our sweet corn is sold out we will make a special price of 50 cts. a peck, or \$1.50 a bushel.

Cucumbers for pickles will probably escape the frost. Ounce, 5 cts.; lb., 50 cts.

Now is the time to start Grand Rapids lettuce for fall use. Put it in beds with boards a foot high around the outside; give it plenty of water, and keep it covered with cotton sheeting when the sun is hot.

You can sow almost any kind of onion seed for sets; but if the fall should be very wet you would have bunch onions instead of sets.

If you want to raise your own seed peas, now is the time to plant them. While the crop will not be as large as spring planting you will get seed free from bugs—at least, that has been our experience; and we have never had them fail to make good peas for table use, when sown in July.

We have some Premium Gems that have come up beautifully within the past week, and there has not been a bit of rain on them since they were planted. We make a special low price on the Premium Gems of 75 cts. a peck, if ordered now.

If you have some extra-early potatoes that are already sprouted, or that you can induce to sprout right away, they will make a crop before frost.

All kinds of radishes will do nicely now if you have the right kind of soil for them. We are getting magnificent ones from our muck grounds right along, without a bit of rain. The Chinese Rose winter is one of the prettiest winter radishes for fall planting.

Salsify, or vegetable oyster, will be large enough for nice table roots if planted now; and we can give you fresh seed, of our own growing, for 10 cts. an ounce, or \$1.00 per lb.

This is also just the time for spinach during this month and next. It is also just the season for all sorts of quick-growing turnips. We consider the Purple-top White Globe as perhaps the best.

Last, but not least, now is your time to sow buckwheat and crimson clover. Sow both at the same time on the same ground; and if you do not get a crop of one you are pretty sure to get a crop of the other. All seeds by mail, 9 cts. per lb. extra.

FRESH LOT OF IMPORTED QUEENS.

We have just received a fine lot of imported queens direct from Italy. A good many orders have been awaiting their arrival, but we shall have a few more choice queens to spare. Price now is the low-

est at any time of the year. Best imported, that is, the very best select, are now only \$4.50; fair imported, \$3.00.

THE RUNNERLESS STRAWBERRY—MORE ABOUT IT.

Mr. Root:—The runnerless everbearing strawberry you lately mentioned in GLEANINGS was doubtless from a plant I sent friend Crawford for trial last year. The fruit is not much larger than a raspberry, and shuckless. I have never known a plant to send out a runner, because it is their growth habit to make crowns instead of runners. Yesterday I separated the roots of a plant and counted seventy-two crowns, each of which had some roots, or would soon put them out if set in the soil as a cutting. They not only bear continuously from May till frost, but put out again after the first frost last autumn; and I picked a few in December. The fruit is rather soft, and quality fairly good. To those who, like myself, like strawberries in and out of season they are an acquisition. I have not yet sold any berries in our market, and don't know how they will take. They were raised from seed brought over by me in 1891. Everbearing strawberries are common in France. I have now several hundred splendid-looking French and English seedlings.

ARTHUR T. GOLDSBOROUGH.

Wesley Heights, Washington, D. C.

Italian Bees in 10-frame Langstroth hive, at \$4.00.

Tested Italian queen, 75c; two or more, 60c each. Untested, 50c each. Address

OTTO KLEINOW,
No. 122 Military Ave., Detroit, Mich.

Square Glass Honey-Jars.

We have on the way another car load of honey-jars. Four sizes: dimes, half-pounds, pounds, and 2-pound jars. Jars and packing is first-class, and safe arrival is guaranteed in every instance.

Bro. Root seems to discriminate against the Muth jars. Our friends are therefore advised to compare prices in Muth's and Root's catalogs before ordering. We mail these catalogs together.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—We are receiving new comb and extracted. New white comb, 14; extracted, white, 6½@7; dark, 4½@5. Demand very light. Beeswax, 22.
July 20. HAMLIN & BEARNS,
Kansas City, Mo.

CHICAGO.—*Honey.*—We report no new comb honey on market as yet. We anticipate a price of 14@15 cts. for fancy white comb. Extracted will sell at from 6@7, depending on quality. However, it will take a month to establish prices on a firm basis.
S. T. FISH & Co.,
July 18. 189 South Water St., Chicago, Ill.

ALBANY.—*Honey.*—We received our first consignment of new honey from the apiary of I. N. Brown, Clarksville, Albany Co. It is not No. 1 quality. The capping has that unattractive yellow appearance, and we do not think it will bring over 10 or 11 cts. We have frequent calls from summer resorts for fine white honey at good prices.
CHAS. McCULLOCH & Co.,
July 18. Albany, N. Y.

SAN FRANCISCO.—*Honey.*—Honey is firmer, the crop not turning out as large as expected. I quote light amber extracted, 4½@5; white, 5@5½. Comb honey scarce at 10. Beeswax, 27@28.
HENRY SCHACHT,
July 13. San Francisco, Cal.

MILWAUKEE.—*Honey.*—This market continues very much the same for honey as when we reported last. The demand is very slight, and as yet the new crop has not made any appearance. However, the conflicting reports with regard to the possibility of a short supply in some parts of our State have had a tendency to make our market firm on choice old, and we quote choice 1-lb. sections at 15@16; common, 10@14; extracted, in kegs and barrels, white, 7½@8; dark, 5@6. Beeswax, 22@26.
A. V. BISHOP & Co.,
July 20. Milwaukee, Wis.

DETROIT.—*Honey.*—Best white comb honey (new), 14; but little offered. Extracted, 6@7. Beeswax dull, 24@25.
M. H. HUNT,
July 18. Bell Branch, Mich.

BUFFALO.—*Honey.*—Strictly fancy new comb would bring 12@13; other grades proportionately lower. The demand is light yet, and we advise only moderate shipments. Later on we can handle a great many pounds as well as it can be sold anywhere.
BATTERSON & Co.,
July 18. Buffalo, N. Y.

BOSTON.—*Honey.*—Nothing new to note in the honey market. No new has come in as yet, but we expect some every day. There is very little demand. Price for comb, 14; extracted, 5@6.
E. E. BLAKE & Co.,
July 19. Boston, Mass.

KANSAS CITY.—*Honey.*—The old crop of comb and extracted honey is about cleared up. We quote new 1-lb. comb, No. 1 white, 14@15, No. 2, 12@13; No. 1 amber, 12@13; No. 2, 10@11; extracted, white, 6@6½; amber, 5@6. Beeswax, 22.
C. C. CLEMENS & Co.,
July 20. Kansas City, Mo.

FOR SALE.—White comb honey, 14 and 16c. on board cars.
G. R. RUTZAHN, Menallen, Pa.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty.
J. P. IVEY,
Secretary Bee-keepers' Association,
Phoenix, Maricopa Co., Arizona.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c.
OLIVER FOSTER, Las Animas, Col.

S. T. Fish & Co.,

Queens, Either 3 or 5 Banded.

60c each; 6 for \$3.25. These low prices are to induce you to try them. Catalog free.

CHAS. H. THIES, Steeleville, Ill.

Don't Be Afraid to Buy

those fine, tested Italian queens I am offering for 65 cents, just because I offer them so cheap. It is not on account of any inferiority that I sell them so cheap, but because I replace, every year, all of my queens in over one hundred colonies, run for honey production, and what I get for the old queens I consider just like finding. A good many are sold already, but there is a fine lot on hand yet, equal to any in the country. A few misnamed ones at 30 cts. each.

T. H. KLOER, Terre Haute, Ind.

Please mention this paper.

For Sale!

A Hawkeye camera, recommended by E. R. Root, of whom I purchased it 3 years ago, with instruction-book, plate holders, and plates, at \$37.00. Will sell for \$32.00. Has scarcely been used since, and has an excellent lens which alone cost over \$30.00. Also a World typewriter, in good order, for \$3.00; a copying-press, nearly new, for \$3.50; a Victor safe (new), list price \$60—will sell for \$45.00; a 4 H. P. portable engine and boiler, in good order, \$115.00; a rotary pump for lifting water for irrigating, in good order, for \$25.00; a counter-shaft, new, price \$10.00; also a lot of Dovetailed beehives, combs, foundation, and fixtures. Particulars on application. CHRISTIAN WECKESSER, Sanborn, N. Y.

CONVENTION NOTICES.

There will be a meeting of the Southeastern Bee-keepers' Association in Fort Scott, Kan., Sept. 19th, 1895. All are cordially invited.
J. C. BALCH, Sec., Bronson, Kan.

The annual meeting of the Northern Illinois Bee-keepers' Association will be held at the residence of O. Taylor, in Harlem, Ill., on Tuesday, Aug. 30, 1895.
B. KENNEDY, Sec., New Milford, Ill.

The Southwestern Wisconsin Bee-keepers' Association will hold its next meeting at Platteville, Wis., Oct. 8th and 9th, 1895. Come all! Don't get discouraged, even if we haven't got a crop of honey. We shall have a good time at Platteville just the same. Bring your wives and daughters with you. Many interesting subjects will be discussed.

M. M. RICE, Sec., Boscobel, Wis.

A BARGAIN in QUEENS
BY RETURN MAIL.

Either golden or leather-colored. All warranted purely mated, workers to show at least 3 bands, at 50 cts each. Three-band breeders, \$1.00. Golden are from one of Doolittle's very best. Leather queens are from an extra choice imported mother.

Choice tested queens, this season's rearing, from imported mothers, 65 cts. each, ready now. Safe arrival and satisfaction guaranteed or money refunded. No disease.

L. H. ROBEY, Worthington, W. Va.

PRICES SLAUGHTERED

ON THOSE BEAUTIFUL RED-CLOVER QUEENS.

One queen, 60 cts.; two, \$1.00. I defy the world to beat them. Don't fail to try them. Satisfaction guaranteed.
G. R. ROUTZAHN, Menallen, Pa.

QUEENS!

Good,
Better,
Best.

The latter is what I am trying to furnish, with what success a long string of testimonials might startle you, as the season is now prime for the rearing of queens, and in competition with some other reliable dealers I will furnish to any new customer 2 Golden Queens for \$1.00; a straight five-banded breeder, \$3.00. Address

W. H. LAWS, Lavaca, Ark.

In responding to this advertisement mention GLEANINGS.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they wish to dispose of, we will insert notices as below, first insertion free of charge. After the first, 10 cents per line. We do this because there is hardly value enough in these queens to pay for buying them up and keeping them in stock, and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have 25 black and hybrid queens for sale at 35 cts. each.
C. G. MARSH, Belden, N. Y.

We have 35 black and hybrid queens, all very profitable, reared in '94, which we will sell for 25 cts. each, or 6 for \$1.00. Write at once, as we will not hold them long.
RANKIN BROS., St. Clair, Mich.

25 or 30 hybrid queens reared this spring; the very best layers. Some of the colonies have gathered 100 lbs. of honey this season; 30 cts. each.

W. J. FOREHAND, Fort Deposit, Ala.

Special Offer.

For July and August only, to those who have never tried our strain of honey-gathering Italians, we will send one sample queen for the trifling sum of 50 cts. One queen only will be sent at above price to one address. All queens warranted to be purely mated. All orders filled by return mail, weather permitting. Address all orders to

LEININGER BROS., Fort Jennings, O.

Please mention this paper.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All advertisements intended for this department must not exceed five lines, and you must say you want your advt in this department or we will not be responsible for errors. You can have the notice as many lines as you please, but all over five lines will cost you according to our regular rates. This department is intended only for bona fide exchanges. Exchange for cash or for price lists, or notices of offering articles for sale, can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

WANTED.—To exchange 200 colonies of bees for any thing useful on plantation.

ANTHONY OPP, Helena, Ark.

WANTED.—To exchange several good safety bicycles. Honey wanted. Send sample.

J. A. GREEN, Ottawa, Ill.

WANTED.—To exchange 26-in. planer, power scroll saw, all iron; tenoner, and mortiser, for portable sawmill, or other wood-working machinery. Will give a bargain for cash.

GEORGE RALL, Frenchville, Trempe Co., Wis.

WANTED.—To exchange foundation-mills and honey-extractors for honey or wax.

I. J. STRINGHAM, 105 Park Place, New York.

WANTED.—A foundation-mill, in exchange for other goods. L. L. ESENHOWER, Reading, Pa.

WHAT have you to exchange for a 200-egg size Invincible Hatcher?

G. J. STURM, Mt. Erie, Ill.

TWO practical young farmers, both married, want to work some gentleman's farm on shares or for salary; prefer a good stock farm with some rich bottom land. We mean business. Write to-day.

MANLEY BROS., 197 Yale, Mich.

WANTED.—By a young man lately arrived in this country, a temporary or permanent opening in an apiary or gardening business, preferably situated in the State of New York or contiguous States. Applicant knows something of the care of bees, and is fond of a healthy outdoor life. A cheerful home rather than salary an object. Is a trained clerk, with good recommendations.

Address C. C. DOORLY, 355 W. 31, N. Y. City.

WANTED.—To exchange steam-pump for foundation-mill, Dovetailed hives, or foundation.

E. SIMMONS, Potsdam, Dade Co., Fla.

WANTED.—To buy 2 tons extracted white-clover honey, in 60 lb. tins.

GEORGE G. WILLARD,
270 Pearl St., Cleveland, O.

WANTED.—To rent or buy an apiary in basswood belt of Wisconsin.

E. BARBER,
Sherburne, N. Y.

WANTED.—To exchange latest improved Marvel magic lantern, best quality (cost \$45), also 100 choice views, for honey, beeswax, or offers.

E. E. SLINGERLAND, Troy, Pa.

WANTED.—To exchange bees in new 8-frame L. hives for a ladies' bicycle.

W. D. SOPER,
Jackson, Mich.

Feeding Back

Instructions regarding the selection and preparation of colonies, preparation of the feed, manipulation necessary to secure the rapid capping of the combs, time for removing the honey, and how to manage if a few sections in a case are not quite complete; in short, all of the "kinks" that have been learned from years of experience, and the "feeding back" of tons of honey. Price of the book, 50 cts.

Queens By Return Mail.

Remember that I am selling nice, yellow, tested, Italian queens, of this year's rearing, at \$1.00 each, or six for \$5.00, and sending them by return mail every time—have been doing so for two months. Advanced Bee Culture and one queen for \$1.25. The book, queen, and REVIEW one year, for \$2.00.

W. Z. HUTCHINSON, Flint, Michigan.

Proof Beyond Doubt.

A customer, looking over my 400 hives in home apiary, said, "Where are your bees? Mine were flying all around thick this morning." I said, "Just stop; look down at any hive." He was amazed. They were just pouring in thick with their heavy loads. This proves two things—they can't be excelled as workers, and quiet.

I opened several hives. He had no veil; was in the apiary ½ of an hour; was not bothered once. Try them. Untested guaranteed queens, 75c. Send for wholesale price list.

Wm. A. Selser,
Wyncote, Pa.

Golden Italian

Queens by return mail, from a breed-er obtained of Doolittle, which he selected and tested out of 1000, for his own special use; he said this queen is a better one than the

World's Fair Queen,

which was valued at \$50.00. Also

Italian Queens

from one of A. I. Root's very best imported breeders; price of queens, untested, 55c; six for \$3.00; 12 for \$5.50; tested, \$1.00 each; 6 for \$5.00. No disease. Shall run 400 nuclei. Ask for free circular, which may be worth dollars to you if you buy queens. Safe delivery and satisfaction will be guaranteed in each and every case.

H. B. QUIRIN, Bellevue, Ohio.

SECTIONS, BEE-HIVES, SHIPPING-CASES

We make a specialty of these goods, and defy competition in quality, workmanship, and prices.

Write for free, illustrated catalog and price list.

STRAY STRAWS

FROM DR. C. C. MILLER.

CRIMSON CLOVER won't count for much as a honey-plant if its chief use is to plow under before blooming. But then, some of it will be used for raising seed.

I WOULDN'T WORRY much whether it was stored in a large or a small hive, if I could have, like that Nevada man on p. 551, a steady honey-flow of $\frac{3}{4}$ to 3 months.

TWO THOUSAND cubic inches is the capacity of brood-chamber C. W. Dayton has reached in the last 13 years (p. 551). That's the figure Quinby settled on 40 or 50 years ago.

DID YOU EVER see bees gather pollen from sweet clover? If you did, what color is it? My bees never seem to gather any. [Honey alone seems to be what they are after around our sweet clovers.—ED.]

TELL YOUR WIFE if she wants nice bread-crumbs, to have *very dry* slices of bread, save them up in a paper bag from time to time, and mash them with a rolling-pin. Then dip in them your meat to fry. [I'm going to try it. It tastes good in imagination already.—ED.]

C. W. DAYTON doesn't want to be "encumbered by unnecessary stores and combs in the hives in the busy season." What harm does an extra comb of solid honey do in the busy season, providing there is extra room for it in the hive? I don't know of any except the weight in handling. Do you?

SWEET CLOVER is now at its best, July 15. Bees don't commence on it till 8 or 9 o'clock, but are thick on it the rest of the day. Probably they can do better on something else early in the morning. [Some day, if it keeps on spreading in the waste places as it has been doing for the last four or five years, we shall value it more than we do now.—ED.]

MY LITTLE PATCH of crimson clover, sowed this spring with oats, is not an immense success. July 15 I found some stalks in bloom a foot high. But it has been through a bad

drouth, and is overshadowed by heavy oats. I suppose it never ought to be sowed in the spring, and I am afraid it will hardly stand one of our winters.

FOR YEARS, following the lead of Adam Grimm, I had a ventilating-space of $\frac{3}{8}$ inch at the back of my hives; and, strange to say, it was never used as an entrance as Doolittle fears, p. 560. But my ventilating-space was at the top, and he may mean at the bottom. I think it helped to keep down swarming, but it retarded the capping of sections at the back end.

TIN TAGS for numbering hives are to be listed another year, perhaps (p. 561). Good! all but the "perhaps." But I don't want to wait till next year. Some of my old tags are lost, and some are getting dim. I can tell the numbers by the place in the row, but I want them correctly numbered before going into the cellar. Punch a little hole in each, to push a half-inch nail through.

CRIMSON CLOVER, according to a footnote on p. 561, is to be sown "about the time corn is cultivated for the first time." Didn't you mean just before going through with the cultivator for the *last* time? [Yes, this was a mistake of our business manager, Mr. Calvert. Only a few advance sheets, however, like your own, had the misprint. A. I. detected the error, and the type were changed.—ED.]

TO SHAKE BEES off combs, I have for years followed Doolittle's plan as learned from him, and given on p. 559; also the plan given in the footnote. For very heavy combs I like Doolittle's plan best, and the editor's plan for combs of medium weight. For very light combs I use a still different plan. Hold the frame in the left hand by one end of the top-bar, and pound on the back of that hand with the right fist.

FRANK BENTON is named on page 559 as a good man for a government apicultural station. Hardly, if he'd be as slow about getting out reports as he has been about getting out the report of the St. Joe convention. [That may be; but I was thinking of that splendid ability he could use if he would; and would he not, under

government pay? He has already made some valuable reports as touching apiculture for the Department of Agriculture.—Ed.]

I DON'T KNOW whether it's best to have more than one place for entrance to a hive; but I notice that, when there's a small hole half way up the front of the hive, the bees crowd it a good deal more than the regular entrance. It's an old-fashioned way; but as the bees seem to like it, isn't it just possible it's a good thing? [That practical bee-keeper, Mr. Julius Hoffman, of "Hoffman-frame" fame, with his several large apiaries believes in having two entrances—one at the bottom and one at the bottom of the second story. His hives are deep.—Ed.]

A SCREW IS LOOSE in the reasoning at top of page 551. Because a ten-frame hive contains only seven frames of brood, it is argued that an eight-frame hive will have only five. I think one of my colonies that had seven brood in a ten-frame hive would have nearer six brood in an eight-frame hive, for it would have much brood in the outside frames of the small hive, and none in those of the large hive. [I think you are right; but I supposed you would not assent to Snell's argument here.—Ed.]

YOU'RE RIGHT, Ernest, on page 549, in saying that I had great difficulty in getting queens to lay in a second brood-chamber. But you may also remember that, in controversy with friend Hatch, I insisted that my queens went back and forth readily, and kept eggs in two stories. I'll see you about this later on. [Do you mean to insinuate that I got on to the wrong side of the fence, i.e., Hatch's side? Really I had forgotten which side I was on. I'll look out next time.—Ed.]

"THE SURPLUS will be a little whiter in appearance where there is a little capped honey under the top-bar than where the space is taken by brood," says F. A. Snell, p. 550. That is, sections are darkened if too close to the brood; and because I can't make sure of the strip of honey to make the brood keep its distance, I want a top-bar not less than $\frac{3}{8}$ thick. [Here is a point for the anti-thick-top bee-keepers to consider a little more than they do; but this is not the only point in favor of deep bars.—Ed.]

RUNNERLESS STRAWBERRIES (p. 573) will be objected to by those who don't want non-swarming bees; but I'd like to have a few of each. But I hardly want stingless bees till Sunday-school teaching has worked a little deeper into Marengo boys. [The real stingless bees, and we have tried them, are no better than bumble-bees. Yes, at our out-yards I'd rather have bees a little cross, and with good long stings. One of our colonies at our bass-wood yard was robbed early in the spring. Fortunately, the thieves encountered one of the crossest stocks. At any rate, they got no honey, and it was evident that they left in post haste.—Ed.]

FOUL BROOD can not be affected by drugs, and it's no use to try any thing in that line, seems to be the verdict on this side the water. May be. But in the face of so much testimony in favor of drugs from good men on the other side of the water, it seems to me pure pigheadedness to refuse to make any trial. If I had a case of foul brood in my apiary I would at least use in the healthy colonies some of the drugs that have a reputation as preventives. If it did no good it could do no harm. [After you had tried as much as we, and failed, your courage would be weak.—Ed.]

SINCE WRITING that "straw" about "tin tags," I find an amendment on p. 564 in the shape of manilla tags. My tin tags have lasted a good many more than "four or five years," and the white paint is still pretty good; but on some of them the black figures are wearing off the white paint. I first tried manilla tags, but in less than a year I one day found them all torn off. But that may have been a piece of malicious mischief. [There, now, you've spoiled my scheme. Seriously, perhaps we had better give up the manilla, and consider again the tin tags. To make them in a wholesale way, and cheap, we must have time to figure. Yes, we'll list the tin tags if they are the best. The sample you send is in good condition.—Ed.]

THE BIG CONVENTION AT TORONTO.

HOTEL ACCOMMODATIONS, ETC.

By R. F. Holtermann.

Friend Root:—I have just been in Toronto to arrange for the North American Bee-keepers' Convention. You are aware that the first session is to be on the evening of Sept. 4th. The convention will meet in the auditorium, normal school. As the meeting is during the first week of the Toronto Exhibition, I expected to be unable to make arrangements with any first-class hotel for reduced rates; but I have succeeded. You will remember the hotel at which members stopped in Brantford when the convention was held there. You were all more than satisfied. Well, the proprietor of that hotel, Mr. Palmer, is now proprietor of the Palmer House and the Kensington, in Toronto. I do not know whether the bee-keepers made so good an impression upon him before, or what is the reason: sufficient to say, he, after a little, consented to give the following rates: Per day, \$1.50, providing members double up. If they require separate beds, \$1.75 per day. This is at the Palmer. The Kensington, just across the road from the Palmer, is upon the European plan—rooms 50 cents and up. In the vicinity are good coffee-houses,

etc., where meals can be secured at from 10 cts. up, depending upon the wants and tastes of the individual—or, perhaps, to speak more correctly, the desires and capacity of the individual. The street-car passes the hotel, and it can be taken within a block of the normal school, without change. The car also runs directly to the exhibition. The hotel is also two blocks from the union station, and not much further to the boat-landing; so I think we are fortunate in this respect. There will be reduced rates to Toronto, covering Canada. Michigan will have a single rate, return tickets. There will be other very low excursion rates from various points in the United States, of which notice will be given you later. Those not within those limits should take regular rate till they reach such territory, and then the excursion rate to Toronto. There will be very low boat rates via Lake Erie and Lake Ontario.

The honey-flow has been rather poor, but I believe there is a very general determination to attend the North American Bee-keepers' Convention in Toronto. The leading papers over here are giving us every assistance, and the meeting will be well advertised.

Brantford, Ont.

[We may be sure that no stone will be left unturned by Bro. Holtermann for the convenience and accommodation of the bee-keepers. We were treated handsomely at Brantford.—ED.]

HOW MANY BEES IN A LARGE SWARM?

SOME INTERESTING EXPERIMENTS OF HOW A BEE-ESCAPE WAS USED TO COUNT THEM ONE BY ONE; WHAT IS THE AVERAGE NUMBER OF EGGS A QUEEN WILL LAY PER DAY? AND WHAT IS THE MAXIMUM?

By J. L. Hyde.

Perhaps what I am writing may be old to you; but if not, you may have it for what it is worth.

I have been weighing my bees that swarmed this summer, or three or four of them, to see how many constitute a swarm; and the best that I could do I could not make out more than 7 or 8 lbs. This would make about 2100 or 2400 by my reckoning. I had a swarm come out July 3, that I counted, and I want to tell you right here how I counted them. I had the queen clipped, so I caught her when she swarmed, then covered the hive with a sheet so no bees could go back into the hive. After I had caged the queen I put her into a small basket and hung it on a stick a little way from the hive (the bees had clustered on a tree while I was doing this); and when the bees returned they all went into the basket with the queen. I then shook the bees out of the sections (as I had already put the sections on), and made them cluster with the others that were in the basket. I then took out all the old comb with brood, and carried these to a new hive,

after shaking some of these bees off the combs, and getting them also to alight with those that were clustered, until I had 8 lbs. in the basket. Then I took a small wooden box that would hold about two quarts, and scooped into it a little over $\frac{1}{4}$ lb. of the bees.

Before they went into the hive, when hiving them I placed the box with the bees in it on the Little Detective scales that I bought of you. I had ready in my hand at this time a Lareese bee-escape; and when the bees had flown out of the box sufficient to weigh just $\frac{1}{4}$ lb. without the box, I clapped the bee-escape on the box so that no bee could get out without going through the escape right before my eyes. I then set the box on to a board, and by puffing a very little smoke in among the bees they were in a commotion, and very soon they commenced to march out through the escape in single file, and they came along just about as fast as I could count them, until they were nearly all out. Well, I counted 747 bees in $\frac{1}{4}$ lb., which would be about 3000 in a pound. Now, if there were 3000 in one pound, there would be in 8 lbs. 24,000, which were about all that the hive contained. There might be about one pound more that I carried with the brood to the new hive, together with the ones scattered about the ground and hive. This is about as large a swarm as I have.

Now, what I should like to know is, what becomes of all of the bees if the queen lays 3000 eggs per day, and her eggs all hatch into bees? Doolittle says that she sometimes lays more—4000 or 5000, I think. If she lays only 3000 eggs per day, in 21 days she would have 63,000 eggs and brood; and in 21 days more there would be that number of bees which are not able to fly much, so they would not die by wearing out their wings. Now, we will wait three weeks longer, and have as many more; and the first three weeks of bees would not be all dead yet; so we should have by this time something like 100,000 bees; that is, in a six-weeks' hatch we should have that number; and the fact is, we do not have more than a quarter as many. Wouldn't it be better to say that the queen lays on an average 1000, and seldom lays 3000 eggs? Or will some one tell where the bees go to?

Pomfret Landing, Ct., July 16.

[Years ago, from the most careful estimates we could make, not counting them one by one, we found that a pound of bees, not filled with honey, as is the case of bees just swarmed out, would aggregate between 4500 and 5000; that when filled full with honey this number would drop down to between 3000 and 3500. You see, you weighed bees that had come out with a *swarm*; and, of course, as they always do on such occasions, they filled themselves with honey to enable them to start building comb, and to leave enough rations besides to enable them to hold out until field-bees can bring in more. Your figures, then, would corroborate very closely those that were obtained by ourselves and friend Hasty years ago.

Along about that time I personally weighed

several large swarms; and the largest that I remember of weighed 9 lbs. Quite a number reached the 8-lb. limit. After they had been hived for a day or two, and had drawn out some comb, I weighed them again and found in nearly every case they had lost from 25 to 33 per cent in weight. This assured me that it was not in loss of bees but in loss of weight, due to empty honey-stomachs.

With regard to the number of eggs a queen may lay in a day, if I remember correctly none of the authorities, including Doolittle, have claimed that 3000 was the *average* per day, but that the queen was *capable* of laying that number. The experiment can be repeated by any one by slipping an empty comb of newly drawn-out foundation, or, better, partially drawn out, into the center of a populous colony. If all other combs are filled with capped honey and brood, and the comb just put in is the only one available for the queen, it is not an uncommon sight to see 3000 cells in this comb on both sides filled in twenty-four hours. Yet I believe that Doolittle and all the rest of the authorities will agree with you that 1000 would be a fair average estimate. If I am not right in interpreting Mr. Doolittle, he will please correct. While 3000 eggs seems to be the maximum, I think Doolittle may also be right in saying that queens may sometimes lay 4000 or 5000.—Ed.]

DO BEES POLLENIZE STRAWBERRY-BLOSSOMS?

SOME ARGUMENTS ON THE OTHER SIDE OF THE QUESTION.

By John Handel.

Hon. Eugene Secor says bees do not work on strawberry-blossoms, but would like to "take it back" if his statement can be proven false. The readers of the *American Bee Journal* agree with him, with but one or two exceptions—unless there are more, like myself, waiting to have their testimony expressed by some one else.

Now, I am so astonished at the conclusions arrived at from facts brought out by this question that I should like to bring the subject up before the readers of GLEANINGS, especially since friend Secor tries to clinch his argument or corroborate his statement by saying that wild strawberries were just as abundant twenty years ago, before a bee, either domestic or wild, entered his county, as now. Here on the Mississippi bottoms, where our bees are able to gather Iowa pollen, there are numerous wild bees gathering pollen from flowers of all kinds, especially those that bloom early. Some of the readers have undoubtedly noticed them as veritable little swarms hovering around the early pussy willow. Those small wild bees can always be seen working on the blossom of the strawberry, providing we look close (for some of them are so small that the naked eye will barely notice them as a bee). There are various sizes, however—some nearly as large as the domestic bee. They usually have a metallic hue or luster, but differ in color. Those little wild bees are very plentiful here, but I know nothing of their habits, except that they gather pollen. They are undoubtedly natives of this

country. Then why are they never mentioned by those who are trying to rob the carrier of nature's "long haul" egg-basket of its honor? They are surely distributed over a considerable area, else there would not be so many here, and so many varieties of them.

I have also seen the domestic bees work on the blossom of the strawberry—not always—neither do they on white clover or buckwheat, but probably one year in five. Here the strawberry blooms at a time when the bees can gather pollen from a dozen different sources; and unless frost, etc., destroy the buds of some, the bees choose that which is best or most abundant, and probably, therefore, neglect the strawberry. But this occasional or periodic visitation of flowers by the bees may be one of nature's wonderful laws. Stock-breeders are well aware of the fact that a certain amount of inbreeding is necessary in order to establish an improvement. Queen-breeders also try to imitate nature. After crossing choice individuals they are satisfied for a time, breeding in that strain until the type is a permanent fixture.

Last year bees in this locality paid little attention to white clover: just now what little there is left is in bloom, and but very few bees can be seen working on it; yet there is almost nothing else for them to do. Most of them are clustered outside of the hive, seemingly waiting for something to turn up. Now, if considerable seed is formed in those two crops of clover, would the fact that but few bees worked on it prove that bees do not pollenize clover? Bees work on the blossoms of buckwheat only after a dew; and unless the temperature drops sufficiently at night to leave condensed moisture on the flowers they are apt to blight, and no seed will form. Is it the wind, cold, or wet? or do bees pollenize the blossoms of buckwheat?

Savanna, Ills., June 17.

[One good witness to the fact that bees have been actually seen to work on strawberry-blossoms is worth more than a dozen claiming they never saw such a thing; but, taking it all in all, in view of what friend Secor has to say (and he certainly is fair and honest in what he says), bees do not in all localities work on the strawberry; and perhaps in localities where they have been known to do so it is only occasional.—Ed.]

THE PHILADELPHIA BEE-KEEPERS' CONVENTION.

The annual summer meeting of the Philadelphia Bee-keepers' Association was held at Woodcliff apiary of Wm. A. Selser, Jenkintown, Pa. The new trolley cars on York Road being open this year for the first was the means of bringing a large delegation from the city. The meeting was called to order at 2 o'clock by Pres. Henry Townsend. After welcoming the guests he gave a lecture on the general construction of the honey-bee, and its work, illustrated by several large charts that had just

been received by the association, from England. This was highly appreciated by the members, and was the means of getting a large number present to become deeply interested in bee-keeping. After the general business was disposed of, which followed the president's address, Mr. John Shallcross, of Philadelphia, read a very interesting paper on the relation of bees to fertilization of plants and flowers. This was followed by an address by Mrs. Thomas, of New York, who has been trying to get authorities to establish an apiary in Central Park, New York. She is now in Cincinnati, O., trying to interest authorities there in establishing a public apiary in their park.

F. HALMAN, JR., Sec.

Wyncote, Pa., June 13.

[Mr. Selser is one of the queen-breeders who has lately come strongly into prominence. He is an enthusiast on the subject of bees, and has done much to enhance the interest of the pursuit in and about Philadelphia. It is with pleasure that we show you one of his yards. Wyncote is simply a suburb of Philadelphia.—Ed.]

CAGING A QUEEN AT SWARMING.

POST-CONSTRUCTED QUEEN-CELLS: SECTIONS AND TIERING UP: QUESTIONS OF A BEGINNER ANSWERED.

By Dr. C. C. Miller.

A correspondent writes:

I have six colonies of bees, in which I take great delight; but on account of poor health I desire no increase. So when the bees swarm I have practiced the plan given on page 69 of "A Year among the Bees." Cage the queen; in five days, cut out queen-cells, and, five days later, cut out cells again and liberate the queen. Last year the plan worked like a charm. This year it failed in one case. The swarm issued May 3, and I caged the queen and put her where the bees could care for her. May 8 I cut out queen-cells, and May 13 I cut out queen-cells and liberated the queen. May 30, or 17 days from the time I liberated the queen, the swarm came out again. Knowing the queen was clipped I was in no hurry to cage her; but in a moment I saw the queen rise, and fly among the bees in the air. Then I knew it was not my old queen but a young one. On examination I could find not a sign of a queen-cell left in the hive; and how could they make a queen-cell with no eggs or young larvæ? and why should this last queen leave the hive with no sign of a queen-cell in the hive? It was impossible for this young queen to be fertilized, as she could not have been old enough. If I kept her in the cage she never could be fertilized. Please explain the case and say what you would do. J. S. F.

I don't know for certain; but I can at least give a guess as to one way. You cut out queen-cells May 8, and the bees immediately started a lot more. May 13 you cut them out again, but this time one escaped your notice, for these post-constructed cells are sometimes exceedingly difficult to detect; and somewhere about May 20 a young queen hatched out. May 30

she flew out to meet the drones, and the bees flew out with her. Possibly if you had left the swarm alone it might have returned to the hive; and yet, bees are freaky things, and you never know for certain what they may do. In any case, I don't think I would cage such a queen, but just return the swarm to the hive, and I don't think you would need to return it many times before the bees would settle down to business and give up their foolishness.

SOME QUESTIONS AS TO WORKING FOR COMB HONEY.

I believe you make a specialty of comb honey. This I have been doing on a small scale, and desire a little information to offset my inexperience. I should be obliged if you would answer my questions in GLEANINGS.

1. What style of section do you think the bees work most easily in? I am using the "three opening;" but this debars me from tiering up, and I thought it might be advisable to change.

2. Do you advocate "tiering"?

3. Do you use the eight or the ten frame hive for section honey? Mine are ten-frame, as I thought that I could contract a ten-frame but could not expand an eight-frame hive. W.

1. I don't believe the bees care such a wonderful sight what kind of sections you give them; but I suspect that, if they expressed a preference, it would be for that which comes the nearest to a regular brood-frame. The reasons in general for using one kind of section in preference to another are because we want what will suit the convenience of the bee-keeper, and especially what will suit the demands of the market. For these reasons the $4\frac{1}{4} \times 4\frac{1}{4}$ section is very popular. As to the width of the section there is not so much agreement. The tendency seems toward a narrower section than that which was at first used. I think nearly every one used them $1\frac{1}{8}$ at first; but at present there are in use sections $1\frac{3}{8}$ wide, $1\frac{3}{4}$, $1\frac{1}{2}$, and I think there are some who use $1\frac{1}{4}$. Before answering this question further I will anticipate the answer to your second question by saying that I would not have a section that would not allow tiering up, so I would not have a section without open top. Mine are open top and bottom. I have tried them with open sides, but could discover no particular advantage, with the disadvantage that they are not quite so safe from marring in handling.

2. I practice tiering. I think we can not well get along without some way by which we can give the bees additional room without waiting for them to finish entirely what sections are on. If sections have closed tops, and are placed on top, there can be put on, at one time, only a single tier. With a hive no larger than ten frames this will allow only 28 to 32 sections, and a strong colony will easily work on more. Then when they are nearly finished there will be a loss of time when the bees might just as well be filling up some fresh sections. With a strong

colony and a flush harvest I should want at least 40 one-pound sections on at once.

3. I used ten-frame hives, and then cut them down to eight frames. If it were to do over again I would try side by side the two sizes before changing them all. If you will contract half your hives to eight frames, and then run the two sizes side by side for two or three years you will be able to come to some decision. I'm obliged to confess I don't know which is best.

Marengo, Ill.

RAMBLE 137.

IN CALAVERAS COUNTY.

By Rambler.

WHEN we were passing through San Francisco we learned from a reliable source that Bro. Pryal,

our genial fellow-traveler, had also made his escape from the siren of Eureka, and returned, via steamer and seasickness, to his home, and was, with greater assiduity than ever, engaged—to the Oakland Waterworks. Our informant stated that, every Saturday afternoon, our fisherman friend would be found at the artesian wells of the waterworks, angling for bites. Of course, we judged that our informant was joking, and in this way wished to convey the idea that our friend had not lost interest in piscatorial sport, even in the business whirl of a great city. Our informant also said that our jovial friend Jones, the gasman, was about to move his bees and his household goods to Sonoma Co., where bees, hogs, and poultry would distract his everyday life.

In order to have a little more spice to our journey, the fates conspired to run us into a political whirlpool in Stockton—bands and banners, torchlight processions, rockets and fireworks, and thousands of people, shouting themselves hoarse just because the Democratic candidate for governor had arrived. We did not allow the political furor to have much effect upon us. We moved out of the city due east toward Calaveras Co. A treeless and dry country intervened for a good share of the distance. Dwellings were miles apart, and there was no sign of taste and adornment in their construction, neither were the surroundings adorned with trees and shrubbery. A rough board cabin, without a shade-tree, a rose-bush, or a bee-hive near it, is about as lonesome and desolate a place as one can imagine. Water here was drawn from wells 230 feet deep. It required a considerable rigging and a stout horse to haul up a barrel of water. The horse traveled in a circle, operating a large drum set upright, and the rope was wound upon this. The liquid

was so valuable that the owner preferred we should get water for our ponies further along. In Milton we found liquid of all kinds plentiful. It appeared that every other building upon one side of the street was a saloon, and there was considerable stir here. This is the terminus of the local railroad from Stockton. From this point freighting into the mountains is performed with those big wagons, and all the way from four to twelve horses.

We were now approaching the great mining regions, and continually met that class of men, typical of the mining industry.

After leaving Milton we had another lonely stretch of road through a slightly wooded and hilly country, and it was upon this road that Black Bart and Smiling William worked at the industry of highway robbery. The stage over this route used to carry much gold from the mines, and at such times it was a tempting object to these bold fellows. Owing to the many lurking places for robbers, the gold route was changed to a more open country to San Andreas, so we were not a particle afraid of robbers. We knew well enough that if we were held up the robbers would gnash their teeth in disappointment when they saw the leanness of our purses.

MR. E. H. SCHAEFFLE AND FAMILY.

Angels' Camp is one of the most prosperous mining towns in California; but we halted here only one night, and worked slowly next day up the hills to the town of Murphy. I had for some years had a very pleasant pen-and-paper acquaintance with a bee-keeper here; and he had written me so many valuable kinks in the art of cooking that I felt a wondrous "fellow feeling," and thought that here we should find a

fellow-bachelor, but were disappointed. The half-tone will show the style of bachelor we found; and here allow me to introduce to the GLEANINGS audience Mr. E. H. Schaeffle (Shelfle) and his wife and baby May, Clarence in front, Ernest and Marian in the rear, and Nellie at the right. Mr. S. and family live within the city limits. His lot of a few acres is bounded upon all sides by streets. The cozy house, honey-house, and the apiary, are embowered in a luxuriant growth of fruit-trees, vines, etc. In this well-utilized space there are 135 colonies of bees; and, though near a much-traveled highway on either side, they do not seem to molest travelers to a vexatious degree.

Mr. S. uses the Gallup frame, and produces comb honey, using a section which holds 1 $\frac{1}{4}$ lbs. of comb honey, or thereabouts, which he sells for 25 cts. each. The honey is all sold in the home market, which includes several min-

to each side of a comb for rapid uncapping. Mr. S. had a very good idea, however, along with his uncapping, and not confined to the bread knife. He uses hot water, as many others do, into which to dip his knife. The water is used in a two-gallon stone crock. If the water is put in boiling hot the crock will hold the heat for a long time. Select a crock upon the edges of which there is no enamel. If there is, file it off. Now, when the knife is removed from the crock, draw it across the edge of the crock as you would across a whetstone, and the edge of the knife is kept as keen as a razor, which is no small item in uncapping.

The honey flora in this vicinity consists of fruits, manzanita, buckeye, coffee-berry, a sprinkling of sage, and the blue tarweed. Tarweed is held in contempt by bee-keepers generally in other portions of the State, for it yields a dark honey with a bad flavor, and thus in-

MR. SCHAEFFLE'S APIARY, FRUIT AND BERRY ORCHARD.

ing towns outside of Murphy. The extractor is used sparingly; and upon my first glimpse of him, on the 7th of November, he was extracting honey; and, although the honey he was extracting was from combs he was transferring, a portion of it was new honey; for at that late date the bees were busily at work storing honey.

A VALUABLE KINK IN KEEPING UNCAPPING-KNIVES SHARP.

Mr. S. preferred a common bread-knife to uncap with, and practiced the economical cut. With the broad point of his bread-knife he would take off a capping about as large as a silver dollar, and then wipe his knife; then another dollar size is slashed off, and another wipe. It will be seen that his preference for the bread-knife over the Bingham is from the limited amount of extracting done. If Mr. S. had several hundred combs to extract per day I have no doubt he would be obliged to adopt a trowel-knife, and work the up-and-down cut

tures by admixture not a little of the better grades of honey. But the blue tarweed of Calaveras Co. gives a fine white honey, with a flavor that would please the most fastidious taste; but for all that it has a fault here—it soon granulates in the comb after removal from the hive. Mr. Schaeffle had any quantity of as white comb honey as will be found anywhere; but it was solid, and practically unsalable in that shape; and in this case, unless the honey can be sold immediately, it should be extracted.

Robbing is a severe affliction here. Mr. S. said that, when robbing commences at one end of a row of hives, unless he was there to prevent it they would follow up and clean out every colony in the row. Eternal vigilance is a necessary qualification of the bee-keeper. Sometimes he could prevent robbing by going along and "tickling," as he termed it, the bees at the entrance of each hive with an asparagus-bush. This sort o' stirred them up and put them on the defensive. His best remedy, how-

ever, was a block of 3x4 joist long enough to cover the entire entrance clear across the front of the hive; in the center of this, and on the four-inch side, a notch was cut just large enough for a drone to get through. This, placed before the entrance, would usually cure.

Mr. Schaeffle had also much trouble with brood in his sections. "Queens persisted in climbing above and filling a whole super with brood; and this habit was not indulged in by one or two colonies, but nearly all of the 135. It became a serious matter with him; and, to save his honey crop, the adoption of queen-excluding honey-boards became a necessity. Mr. S. showed us a large number of filled sections that had been spoiled by this pernicious habit of the queen. As there is but little complaint among comb-honey producers in this direction, Mr. S.'s case is exceptional, and rests, perhaps, on the fact that his 1 $\frac{3}{4}$ -pound section holds a comb about the same thickness as a brood-comb, so the queen more readily enters the super.

The best yields in his apiary have been 250 lbs. of comb from one colony. Our friend was busy with his bees, his honey, and his wax. The latter was rendered out upon the kitchen-stove. I admired the forbearance of Mrs. Schaeffle over the little drops of wax that would get upon the floor, and especially when the five-gallon can of wax boiled over upon the hot

stove, and the flames ascended to the ceiling. Ernest ran in with a pail of water; but Mr. S. was ahead of him with a broomstick. Running this through the bail of the can he made for the door with it. All went well until upon the veranda, when a little tilt of the broomstick allowed the can to slide off, and the wax was nicely spread across the veranda floor. These little mishaps are what every bee-keeper experiences more or less, and are admirably adapted to test individual patience; and I am happy to say the Schaeffle family viewed the

matter serenely, and scraped the wax up carefully, and we all rejoiced that the conflagration went no further than the wax.

RAMBLER'S VISIT.

SOMETHING ABOUT "CHINESE TEA."

By E. H. Schaeffle.

I was busy uncapping, when the door of the honey-house opened and the liberated bees rushed out past the face of a grave-looking stranger. As he did not flinch I remarked, "You are no stranger to bees?"

"No," he replied. "I am sometimes called Rambler."

In a few minutes I had met his companion, Wilder; the team was turned in on the grass; Rambler was then made at home, and the boys hung up with me for almost two weeks. Some of you who have been favored with only a "drop in" from them may wonder how I managed to hold them so long. Well, to be honest I played a very small part in it. Wilder, who is a very bright rustler, thought he ought to brush up on some of the rudiments of his education, and, meeting an old lady friend from New Hampshire, who is now engaged in a neighboring town in teaching the young idea how to shoot, put himself under her tuition, and it took some time to complete the course of study. Though he declares she is "all wool and a yard wide," and Rambler—well, now I am as much of a Rambler myself, and he may come back at me if I give him away; but this is the only chance that I'll have at him; so, here goes.

Rambler, like A. I. Root, is a strict teetotaler—so much so that he declined my wife's mince pies; but—oh that "but"! At Angels he handed over his linen to a Chinese laundry; and on going for his wash the "heathen Chinese" handed Rambler a cup of tea. Now, Rambler had frequently heard of the excellence of Chinese tea, and so took it down at one long deep swallow, when he discovered it was—brandy! Coming home, Wilder and myself found our overcoats very comfortable; but Rambler refused to put his on, and gave as a reason that he had his overcoat inside of him, and was very warm.

This was not the only experience here, for the Rambler fell an easy victim to the smiles of a native daughter whom he persuaded to allow him to photograph; but the honor, and the nearness of Rambler, so overcame her that the smiling Betsy could not control herself, but rocked to and fro, and smiled and smiled. Rambler persists that the photo does not do her justice, and refused me a proof; but Wilder proved more susceptible, and so here it is. Let all the Eugenias look and wail.

While here we discussed the bee business in every phase. The prevention of granulation in honey and the clarification of dark honey we found could be accomplished; but each process

required heat, and so all were voted no good. A motive power for extracting was canvassed. Rambler suggested a weight with sprocket-chain, to draw up and let it run down while the operator was uncapping. My suggestion was the wheel and treadle of a sewing-machine, placed under the uncapping-table; from this, and to one side of the operator, a belt running to the extractor, back of and to one side of the uncapping-table, thus making it possible to uncup and extract all at the same time, and keep a perpetual motion, as it were.

SMILING BETSY.

About a year ago I designed a hive holding 12 Hoffman frames, each $6\frac{1}{2}$ inches deep. This, Rambler thought, would work finely in this section. I showed him sections that had been filled to the last cell with brood; but this was an old experience with him, while old with me. It is not desirable, as I lost all of my first crop of honey and close on to 100 stands of bees by the queens laying eggs in all the supers, and some of the hives had three and four cases. Nevertheless, I had about $2\frac{1}{2}$ tons from eighty stands, spring count. While Rambler was here a postal from S. L. Watkins, of Grizzly Flats, El Dorado Co., arrived, stating he would soon be here, and that his best swarms had given close on to 500 lbs. of honey, and were still at it on the day he wrote, Nov. 12th, so that, while Rambler and Wilder have found it necessary to drive all over the State to work off their blues over the total failure of the honey crop in their section, we in this neck of the woods not only do not have to feed, but are fed in this off year by our bees.

From here the migratory bee-keepers, Wilder and Rambler, drove directly home, a distance of 500 miles, which is counted a small ramble by these old perambulators. That their next ramble may bring them this way is my wish.

Murphys, Cal., Nov. 19.

WOOD-BASE FOUNDATION.

DO BEES GNAW IT DURING A DEARTH OF HONEY? COMBS BREAKING DOWN, AND THE REMEDY.

By J. B. Locken.

What time has not been devoted to gospel work I have spent with my bees, making many various experiments with the Schmidt & Thiele brood foundation, hoping by personal experience to ascertain its value.

As soon as it came to my notice I secured several pounds; and while I was stimulating my bees by feeding, preparing them for early artificial swarming. I gave some colonies full sheets of wood-base foundation, placing it in the middle of the brood-chamber. The bees drew it out very nicely, and it was soon filled with solid brood. But one difficulty that I soon discovered in the use of full sheets was that it warped at the bottom. I think the reason for that is, the bottoms of the frames are exposed to the damp air and the moisture of the bottom-board, after the rain, and also because it is near the ground. To remedy this evil I tried half-sheets with better result; but still this did not work to perfection. There was yet room for improvement.

The first of June I formed a number of two-frame nuclei. They now cover about six frames. In these nuclei I have used half-sheets and a third part of a sheet, the latter with most excellent results. I have carefully examined every frame in which I used veneer foundation, and can find only one frame where the bees have gnawed the wood base.

If the white clover would give us a yield for the bees to store honey, I do not anticipate that they would stop to gnaw the "wood base," but would soon have it covered out of sight. But the prospect of a white-clover crop is not encouraging. The clover is abundant and in its height of bloom, but it does not seem to secrete any nectar.

My bees have stored some honey from the small-fruit blossoms, and during that time my nuclei built up and drew out these combs.

□ I do not yet know what notions the bees may take during the cold and damp seasons of the year, as early spring and late fall, when they have nothing to do but gather propolis, and fill up every crack and crevice. I have seen them gnaw large holes in the combs, at these seasons of the year, when I couldn't see any reason for it, except that they didn't want to be idle, for the honey-bee is the very model of industry. Should I run my bees for extracted honey, or expect to move my bees about from one location to another to obtain the benefit of various honey-plants in their season, to prevent the breaking-down of combs I would use veneer foundation.

Several years ago I worked in an apiary of 300 colonies, divided in two yards. From the

home apiary we moved 100 colonies for basswood, of which they gathered 11,000 pounds. As soon as the basswood-flow ceased we moved them again, a distance of about 25 miles—this time on the prairie, for horsemint, which gave an abundant yield that fall. We extracted about 8000 pounds of that.

The second move we made, we were so unfortunate as to have from ten to fifteen colonies break down. I do not remember the exact number. It was a very warm and sultry night, and the roads being rough helped to bring about the sad result. The colonies that broke down were nearly all in Langstroth hives. The Gallup hives came through all right. In cleaning up the broken down hives I noticed that all the combs that had broken down had simply dropped out of the frames, leaving from $1\frac{1}{2}$ to 2 inches of comb fastened to the top-bar. If these combs had been built on wood-base foundation I do not think they would have broken down.

As is nearly always the case, the queen very seldom lays eggs in the top cells near the top-bar, but always leaves a space where the bees usually store honey. As a result, that part of the comb, where all the weight comes, is the weakest, as it doesn't become tough, like the rest of the comb, by breeding. If the combs break down in moving, extracting, or handling, they usually break near the top-bar, where the honey is stored. To prevent that difficulty I am quite confident that the use of a half or a third sheet of veneer foundation would remedy all the defects in that line. It would also keep the combs from sagging as much as they do with a full sheet of common foundation, and there would be no hindrance in cutting out queen-cells.

Now, is there not some way by which a third of a sheet of wood base could be made in with the full sheet of foundation, so if one should desire to put in full sheets and have one-third wood base, it could be done? If that could be accomplished, the question would be solved. There would be no risk to run then, nor fear that the bees would gnaw the foundation in drawing it out. It would prove an advantage in every way, and perhaps the wood base would at last meet the long-felt want of a foundation that would not easily sag nor break down. The use of one-third sheet has proven satisfactory to me. I have as fine a lot of combs in my yard, drawn out on that foundation, as I have ever seen. Further experience will reveal its value; and it may become true, as the editor has already remarked, that "old things that have been discarded and declared valueless in the past have come up again, and demonstrated that there is something of value in them after all."

New London, Wis., June 26.

[Experience years ago showed that bees occasionally show a decided dislike to the

wood in foundation; and during a dearth of honey they would, as you say, here and there gnaw down patches of comb down to the wood. The increased expense, and this propensity on the part of the bees, compelled us to adopt wires instead. Wiring is very cheap; it secures the sheets of foundation firmly in the center of the frames, and, when drawn out into comb, never breaks down. But I must say, on the other hand that I have seen some of the prettiest combs built from wood-base foundation that I have ever seen. I think we have a few of them yet.—Ed.]

POOR SEASONS FOR TEN YEARS.

A DISCOURAGING OUTLOOK: WILL IT ALWAYS BE THUS?

By John Murray.

I should like to get some more goods, but the bee-business has been so poor I can't afford it. It used to be around here so that, one year with another, a colony of bees would average 100 lbs. per annum; but the last good year was when A. I. Root was here (1889). We used to get fall honey nearly every year. When Japanese buckwheat first came around I got \$2.00 worth to get my neighbors to grow it; but I don't think I got \$2.00 worth of buckwheat honey since, although it has been grown close by every year. Now we are in the middle of the basswood bloom. Other years it commences to bloom about the 9th of July. The first tree I noticed in bloom this year was on the 24th day of June. The nights are so cold that light frosts formed in the hollows on the 28th of June. Bees have made no honey to speak of, and they are weak, and on an average have not over half as much brood as they ought to have at this time, and drones are very scarce. It is a sign of queenlessness to see them around. My bees made a little honey on basswood last week, but not sufficient to whiten the combs. The dry weather in the spring killed the white clover, while the sumac and some other plants that had their leaves frozen, and bloomed out again, will be late, so there is a chance yet. There is certainly so much bloom here in summer time that, if the conditions are right, we shall get honey any way.

There seems to be a great change coming over this country. We don't have the thunder and lightning we once had. The springs are all drying up, except the deep ones. I don't think the creeks or the Wisconsin River is over half as big as it was, and it is the same all over the West. Thousands of lakes and ponds that had fish and muskrats in them are dried up, and flax is grown in their bed; and so large a stream as the James River, in Dakota, is so low it can be waded almost anywhere. That is what I am told; and if this drying-up process goes on as fast in the next thirty years as it has in the last, I would not give much for this whole section west of the Dakota Lakes.

Woodman, Grant Co., Wis., July 1.

[But, friend M., it has not been ten years since I made that pleasant visit through Wisconsin. It is true, we have had more drouths than usual for several years; but it is not very long ago that our seasons were so wet, especially the fore part of the year, that people really longed, and perhaps prayed, for the ground to get dry enough to work as it had been in the good old times.—A. I. R.]

REARING QUEENS TO ITALIANIZE AN APIARY.

Question.—My bees are all pure Italians, and all my neighbors for miles around have either blacks or hybrids, so that it is impossible for me to Italianize my bees, the neighbors' bees being all kept in box hives, and therefore having a great many drones in the summer season. How can I, in rearing queens for my own use, secure them purely fecundated? and what would be the best time of the year to rear such queens?

Answer.—There are several ways of doing this, nearly all of which I shall speak being used by myself to a greater or less extent during the past twenty-five years. A good and practical plan is to give to all of the colonies, which have good Italian queens, one or two frames of drone comb, so that large numbers of drones will be reared in your own apiary, which will be very likely to secure the pure mating of one-half or more of your queens; and when one is found that is impurely mated, kill her and give the colony a queen-cell from your pure breeder, and try again. As your colonies increase, your drones will increase also; and the more drones reared in your Italian colonies, the better will be your chances of having all purely mated.

The next plan would be to give capped brood to your drone-rearing colonies early in the spring; and this, together with a little warm feed given each day, will cause the desired queens to lay in the drone comb early, through the stimulation given, thus giving you strong colonies with plenty of drones, before your neighbors' colonies rear any drones. As soon as any drone brood has been capped from three days to a week, start to rear queens, and in this way you will have your queens ready for the first drones which appear. The main objection to this plan is, that such rearing of queens comes at a time when it is likely to interfere with your crop of honey; for in all queen-rearing the colony is thrown out of its normal condition; and whether the old queens are taken away from their colonies to give place for queen-cells desired, or nuclei formed to take care of these cells, this interference comes at a time when all should be booming as much as possible along the line of rearing the laborers (bees) in time for the honey harvest, which, as

a rule, will be from 30 to 50 days ahead. I am one of those who believe that impure stock, with a good yield of honey, is to be preferred to pure stock and little surplus honey.

Another plan is, to wait till fall about rearing queens, when, if you can preserve the desired drones till all your neighbors' drones are killed off, you will have every queen to mate with the drones you desire. To preserve drones, gather all the drone brood you can find in the apiary from the queens you have decided shall be drone-mothers, and mass this brood in one hive, tiering it up, if necessary, to accommodate this brood and lots of honey; for, the larger the hive and the more honey it contains, the better your chances of having the drones preserved in large numbers. When this drone brood is massed, the queen should be taken away from the colony; and as often as a new queen commences to lay she should be taken away also, and this colony kept supplied with sufficient worker brood to keep it in a prosperous condition, so that it will not be robbed of its honey on account of fewness of bees to guard and care for it. If you wish that all the drones which your queens mate with shall be strong, robust fellows, on some cloudy day (when it is not so warm that you will be troubled with robbers, nor so cold that the bees will gather in bunches to keep warm) look this hive over and hand-pick the drones, killing all which you think are not such as you would desire. To best do this, take out the first comb and pick out as above, when it is to be set into an empty hive, set on the stand originally occupied, and thus when you have gone over every comb, and the drones clinging to the sides of the hive and bottom-board, your colony is just where you want it, without any extra handling of the frames. You are now sure that every queen will come as near perfection as is possible along the line of right mating; and were it not that this plan requires much extra work and care in feeding the queen-rearing colonies, that fairly good queens may be reared out of season, and, also, that this late manipulation of colonies forfeits our chances for successful wintering, I should say that this was the plan above all others to secure purely mated queens. But with all of these drawbacks, I have thus reared queens which proved of great value to me.

Another plan is to take a hive containing our best hand-picked drones to some locality isolated four or five miles from other bees; and, as often as may be, take a load of nuclei, supplied with queens from our best mother, they being from three to five days old, to this isolated place, leaving them there from eight to ten days, when they can be brought home with laying queens, which will, as a rule, be all mated with the desired drones. With a proper rack fixed on any light spring wagon, from 12 to 25 can be carried to and fro at one time, so

that this is not as laborious as it at first appears, and it has this advantage: our queens can be reared at a time when nearly every queen will be perfection itself, all being reared in the height of the honey season, when the best queens can be reared with the least work.

Still another plan is to rear the queens and drones in the best part of the honey season, and, when ready, take the drone colony, and as many of the nuclei as have queens of mating age, to the bee-cellar at about 11 o'clock A. M., and leave them there till 4 P. M., when they are to be brought out and allowed to fly, after all other drones have ceased flying for the day. If each nucleus and the drone colony are fed a little diluted sweet just before setting out, and the hives set facing the sun, queens and drones will fly the same as they would were it three hours earlier in the day. If you have no cellar handy, the bees can be confined to their hives for the five hours spoken of, if ample ventilation is provided, when the result will be the same.

But after a trial of these I have come to the conclusion that, for the practical bee-keeper, the first plan is the one to follow; and, let me whisper in your ear, the mismated queens which you will get by this practical plan will give you just as good results in honey as will any of the purely mated queens; and *honey* is what the average bee-keeper is after. What the average bee-keeper wants is one or two good pure Italian queens to rear his queens from; then let them mate as they please; and let me assure the reader that such a mode of procedure will give perfect satisfaction so far as honey-gathering is concerned. Of course, it will be necessary to have a good queen to rear stock from every two or three years, else we shall soon run into a race of bees we shall not be satisfied with.

THE STEPHENS FEEDER.

A FULL DESCRIPTION OF IT.

By Geo. W. Stephens.

Last fall I had 23 colonies of bees to feed; and, not having feeders enough, and having waited in vain for a fall flow of nectar until I thought it was too late to send for more feeders, I hastily made some which I found to work satisfactorily; in fact, I like them for many reasons better than any other feeder I have ever seen or tried. I mail one to GLEANINGS and will also try to explain to its readers how it is made. It is not patented, and any one who is handy with tools can make them. They

could be sold so low that it wouldn't pay one to make them for himself.

Take a piece of board $\frac{1}{2}$ inch thick, and saw it in the shape of a Bland dollar, but five or six inches in diameter; then cut eight notches, equidistant, around the edge, about as large as a $\frac{1}{2}$ -inch auger-hole; and with an extension bit bore a $3\frac{1}{8}$ hole $\frac{1}{4}$ inch deep. See Fig. 1.

Get another piece of board, which may be $\frac{3}{8}$ thick, and cut it the same size as the first one; but saw out from the center a piece $3\frac{1}{4}$ inches in diameter, as in Fig. 2. Save the small piece, and nail a cleat across it, as it will make a handy cover when wanted, as in Fig. 3.

Use basswood, because pine and some other kinds of wood seem to give the bees a bad taste in their mouths, and they do not take the syrup down quite so readily. Now get a strip of tin two inches wide, and long enough to encircle the pieces and lap about $\frac{1}{2}$ inch. Nail it around the first piece so that about $\frac{1}{2}$ inch of the strip will project on the under side. Nail the second piece flush with the upper edge of the tin. Take a Mason glass jar, either a pint or a quart; knock the glass lining out of the cap, and make a few perforations close to the top of the cap. Don't make the perforations too large; the size of a common knitting-needle is about right.

Now your feeder is finished, and it is a good one. Spread a piece of burlap over the brood-frames, with a hole cut in its center 3 or 4 inches in diameter; set the feeder over the opening; fill the jar with syrup, or sugar and water; invert it and place it top down in the feeder, as in Fig. 5. Put on an empty hive-body, and spread over the bees around the feeder pieces of carpet or any thing that will keep the heat of the cluster in. Some might prefer to use a board with an opening in it instead of the burlap. Those who prefer to feed sugar and water instead of syrup will find that, by putting several pieces of flannel or other material in the mouth of the jar before screwing on the cap, they will get the percolation principle to per-

fection. Two or more feeders may be placed on the hive at one time if it is desired to feed faster. The feeder is sufficiently deep so that the jar will not tip over, and every thing about it is close enough to prevent the escape of the heat of the cluster. Another advantage is, the jar being glass, one can see when it needs refilling, without taking it up, which is impossible with a tin can or crock. I call it, for short, the Stephens bee-feeder.

Dennison, Ia., Jan. 24.

[This came some time ago, as will be seen above, but was overlooked, and hence we produce it now in anticipation of fall feeding.—ED.]

SCARCELY ANY WHITE HONEY.

We are getting scarcely any white honey in this section, and it is so dry we fear we shall get but little dark honey, as the buckwheat will be a failure unless it rains soon. D. COMPTON.

Troy, Pa., July 19.

THE FIRST FAILURE.

The honey season is now so far advanced that I am able to report to a certainty a total failure—the first in a lifetime. E. E. EDWARDS.

Alexandria, Ind., July 15.

ONE OF THE WORST SEASONS EVER KNOWN.

I have been in the bee-business for several years, and this is one of the worst I have had. The spring frosts cut off the bloom, and, followed by dry weather, left the bees in bad shape. I have not had a swarm, neither have I taken any honey, and shall have to feed soon to keep them living. I have about 40 stocks.

R. W. BURRELL.

Caledon East, Ont., July 19.

MOST UNFAVORABLE SEASON.

We are having the most unfavorable season here that we have seen in more than 30 years. All kinds of fruits were killed here by the succeeding frosts, commencing May 13. We have had but very little rain since the frosts. Meadows are yielding less than a quarter of the usual crop of hay. Pastures are dried up. I am feeding my cows hay and grain daily. Money is tight, and many men are out of work. I have ten colonies of bees which had to be fed until chestnuts bloomed, to keep them alive.

D. H. ODELL.

North Collins, N. Y., July 15, 1895.

UNPRECEDENTED DROUTH, AND HONEY FAILURE.

We have here a season of unprecedented drouth. It is a tough one for farmers, and a dollar does not grow on every bush this year. Rainfall at my place, since the first of February, has been only 7.1 inches, whereas in ordinary seasons the average for the corres-

ponding period is about 18 inches. It is a sandy region here, mostly, and the ground is like dry ashes to a great depth. Forest fires have been running fearfully. Hay and oats are dried up; and even apple-trees, two years from setting, show symptoms of dying. I doubt whether there is a ton of good clover within two miles of me. I have but two new swarms of bees, which came out early in June, both from one hive. A dozen others have not swarmed at all, and they are laying in little or no surplus honey. Sweet clover is the only grass that still looks green and bright under the heat and dryness. But corn thus far is growing finely. Buckwheat has no sweetness.

Muskegon, Mich., July 18.

A. BAXTER.

Bees are doing well at present, but we are needing rain very much. R. B. LARKIN.

Patronville, Ind., June 15.

Bees in this part of the country are doing better this season than they have for several years. MRS. J. N. HEATER.

Columbus, Neb., July 12.

Bees are doing fairly well—have made about two tons of honey so far. H. T. GIFFORD.

Verona, Fla., June 4.

Bees are booming—commenced swarming June 1. Total loss wintering and springing, 15 per cent. I have now 90 colonies.

CHAS. M. WELSH.

East Galway, N. Y., June 3.

The bees are doing well this season for the first time in three years. Our box-hive friends have had no surplus honey at all for three years, but are getting very good yields.

Brownsville, Tenn., June 3. S. H. CLARK.

ENCOURAGING FOR CALIFORNIA.

The honey in Southern California is very fine in quality this season. I have not seen it better in twenty years. A. P. HERRICK.

Campo, Cal., July 9.

HOPES REVIVED.

The heavy rains of this week will bring on the blessed heartsease. We got 1000 lbs. from 23 stands last year, after this time; so our hopes are revived. W. M. MILLER.

Joy, Ill., July 19.

DONE WELL.

My bees are doing well; have increased twofold, because I could not attend to them, but yet are making considerable surplus.

E. G. HEDDING.

Paw Paw, W. Va., July 18.

ALTHOUGH honey is coming very slowly, as intimated elsewhere, from sweet clover, we are compelled to use a tent while working with our queen-rearing colonies.

FOR the first time in several years we have been enabled to fill almost all our orders for queens, from our own apiary. Our trade has not been less; but now that we have gone back to the good old-fashioned method of raising queens, it is an actual fact that we can raise *more* queens than we could by fussing with the new-fangled plans.

BEE-KEEPERS are now generally recognizing the value of the bee-escape. Here is one point in their favor, which I believe has not been mentioned before. Mr. O. R. Coe, an extensive bee-keeper in the Catskill Mountains, at Windham, N. Y., says this of them:

One of the most important uses of the bee-escape, and one that I have never seen in print, is the use of it in keeping out fresh thin nectar the day we extract, by putting on a bee-escape early in the morning, and never at night, as usually told to do; then if there is any uncapped honey it will have been evaporated (or boiled down) by the bees during the night.

THERE is every indication that the meeting of the next North American at Toronto will be an unusually large one; indeed, we always have good conventions over in Canada. It is thought there will be 300 or over in attendance, and half this is a fairly good number for the North American. Let the attendance, enthusiasm, and good will be big—yes, very big. There will be reduced rates on the railways, and unusually low hotel fare. See full particulars elsewhere in this issue, just after Stray Straws.

A COUNT shows that we have, all told, 365 colonies and nuclei, the larger portion being of the latter. The former will give us quite a little crop of extracted honey, but just how much we do not know. A little honey is coming in every day; and as the only thing the bees are working on is sweet clover, the honey will be largely of that kind. Sweet clover is beginning more and more to come in after the regular flow; and even if it does nothing more, it enables the bees to fill out the combs, especially sections nearly filled from clover and basswood.

CRIMSON CLOVER.

WANTED, information regarding the adaptability of crimson clover for bees. We already had an article in the Gardening Department as to when to sow. So much is being said of it in agricultural papers that we should like two or three articles from *bee-keepers* who have

tested it, and are in position to speak of its merits as a *honey-plant*. I am at a loss to know just whom to write to; but I am sure that, among our large family of readers, there are some who can stand up and speak. Hello! it seems the request has in part been anticipated. Here is what a bee-keeper has to say of it already:

I noticed the little clipping about crimson clover, in *GLEANINGS*. It's a great bee-plant, and comes so early it gets ahead of drouth. Every farmer and bee-keeper should buy it. It stands several degrees below zero here with no protection; in fact, we think, with Prof. Mossey, it is hardier than red; will also grow on poorer land, but land can be too poor for it. It should be sown early to insure its wintering; north, not later than last of August. Home-grown seed is much hardier. A. F. AMES.

Claremont, Va., July 18.

We want more reports from a large number, so that we can have a comprehensive symposium on crimson clover. And, while we about it, can some one send us a good photo of the clover? We have many artists in our ranks.

HONEY-CROP FOR 1895.

I WOULD call attention to Reports Encouraging and Reports Discouraging, in this issue. On account of the late frosts, and the drouths throughout the North especially, the honey crop, I am afraid from present indications, will not be even as good as last year; yet, as is always the case during poor seasons, some bee-keepers harvest good crops. I call to mind the case of H. R. Boardman, of East Townsend, O., whose bees, I understand, are fairly rolling in the honey. Neighbor Vernon Burt, a few miles north of us, has done well also. Neighbors Chase and Prince, while they have not had entire failure, have secured light crops. Our bees have done fairly. I am afraid the average, all told, however, from clover (comb honey), throughout the United States, will hardly approximate 15 lbs. per colony. Heartsease and sweet clover and crimson clover, in the North and East, will yield fairly well; and in California, especially in the southern part of the State, while their crop has not been as large as in some other years, it is considered good.

THE AMALGAMATION OF THE NORTH AMERICAN BEE-KEEPERS' ASSOCIATION AND THE BEE-KEEPERS' UNION.

ON page 489 we referred editorially to some excellent ideas put forth by the editor of the *Bee-keepers' Review*, and the matter is now being discussed in the leading bee-journals. There seems to be little or no opposition to the scheme, except from the General Manager of the Union himself; and his opposition is rather big, because he is a mighty man of valor. In the *Bee-keepers' Review* for July he has this to say:

I have carefully read the editorial in the last *Review* on the above subject; and while I fully agree with it as to the object to be attained, viz., organ-

ization, I do not indorse some of the methods suggested or hinted at, to obtain it.

It is well known that "Organization" was my pet theme for years; and what organization the National Society did have was through my efforts in that direction. I have spent both time and money in trying to get up an efficient organization—one that would be a power for good, and at the same time make it a permanent institution. But as soon as the National Society was incorporated, a "howl" went up from some selfish, narrow-minded bigots, who fought it inch by inch, and apparently, at least, accomplished its dissolution—for at the last meeting at St. Joseph they ignored the past, cut down the constitution, threw out the by-laws, all for what? Heaven may know, but I don't. As the report of that convention has never been published, we may never know the "whys" and "wherefores" of their action. Let us look at the history of the matter a little before entering into the discussion of the *modus operandi* proposed.

At the 19th annual convention held at Columbus, O., Oct. 3, 1888, a new constitution and by-laws were adopted by unanimous vote. These documents were prepared by me very carefully, and presented at the convention of the previous year. They were referred to a committee, and that committee referred them back to the convention, without recommendation. Coming before that whole body, they were unanimously indorsed, and then and there adopted.

Article X. of that constitution reads as follows: "A Defense Committee of seven shall be appointed for the purpose of considering the applications of members for defense from unjust lawsuits by those who are prejudiced against the pursuit. This committee shall be the officers annually elected by the National Bee-keepers' Union, which is hereby declared to be affiliated to the International American Bee-keepers' Association. Its President is hereby made a Vice-president of the Association, and its General Manager also a delegate to the International Convention."

Could any thing be plainer? The Union was *officially declared* to be affiliated to the National Society, and its President and General Manager declared to be officers of the Association.

In St. Joseph last fall, this was (if I am correctly informed) all thrown out; indeed, the whole by-laws were repealed, and the Union "divorced." Now, in less than a year, up comes the present proposition to re-marry the two again. The National Association is to marry the Union, as a blushing bride, probably because of her dowry. What child's play and foolishness!

The Union is prosperous and successful, and needs no "affiliation." The National Society is the impecunious party, and must do all the "sparking" if a re-marriage is effected.

As General Manager of the Union I must say, seriously, that no amalgamation can be made unless so determined by a full and free vote of all its members, upon proper presentation of the aims and objects thereof.

I do not believe that the members of the Union will ever consent to have the funds, raised for defense, diverted to other channels, and used for delegates "to see the boys and have a good time." I know that my consent will never be given for such a thing.

THOS. G. NEWMAN.

Chicago, Ill., June 24.

Elsewhere in the same issue the editor comments upon Mr. Newman's article as follows:

The only change in the constitution that bore fruit was that of affiliation—State and other local societies paid \$5.00 per year, and were then affiliated with the North American. But very few societies remained in affiliation more than two years, and this feature soon became a dead letter. The clause making the officers of the Union a defense committee of the North American did not influence the actions of either society. It was a sort of expression of good fellowship, or sympathy, or an indorsement of the Union by the North American; but the Union went on conducting its affairs as it saw fit, and the North American did the same. There was nothing even approaching the "married" relation to which Mr. Newman so figuratively alludes.

The constitution and by-laws were cut down and revised at St. Joseph because time, that sure tester of all things, had shown that the constitution and by-laws adopted at Columbus were not adapted to the condition of things in this country. Change of constitution, affiliation, incorporation, and kindred

changes will not benefit the North American unless made in conformity with existing conditions; and the brightest of us can not always tell when they are so made—only time and experience can demonstrate that.

It may not be the best that the North American and the Union should join forces; but that one society has more money than the other seems a strange argument to advance against such a course. To have money in the treasury is well; to have spent it in a good cause might have been better. I do not mean to insinuate that the Union has neglected to spend money when it could be wisely spent; but neither the Union nor the North American has for its object the accumulation of money. It is not a question of how much money each society has in its treasury, nor which has changed its constitution the more times, but whether, all things considered, it is *advisable* that the two societies join forces?

The Union was organized for a specific purpose, and has done its work well; but a close observer must have noticed that the amount of work it does lessens as the years go by. At first there was more work than money with which to carry it on, while its manager worked for nothing; now he has a salary (and most richly does he deserve it), yet money is accumulating in the treasury. Some excellent and righteous decisions have been secured, and these have a most quieting effect when shoved under the nose of some would-be persecutor. For this reason the number of expensive law-suits has decreased. This is a condition that would naturally be expected, and is desirable. Now the question arises, Would it not be better that some of this money should be used for the good of bee-keeping rather than that it should go on accumulating year after year? (Perhaps a lowering of the fees would be a better plan.) Of course, those who contributed to making up this sum are the ones to say what shall be done with it. By the way, Bro. Newman says this sum was raised for the purpose of defense. This is true; but it is also true that it can be used to prosecute adulterators of honey, to secure legislation—in short, for *any* purpose thought advisable by the Advisory Board.

As I understand the matter, the North American was organized to advance the cause of bee culture by bringing together the leaders in the profession, with a view to an exchange of ideas. As has been often mentioned, the journals have greatly lessened the value of the Association in this direction. This condition, coupled with poor honey seasons, has made some of the late conventions rather poorly attended. We, as bee-keepers, ought to recognize these changed conditions as regards both of these organizations. Many bee-keepers now belong to one society who can not afford to belong to both, or think they can not. In a union of forces there would be a saving of expense, an increase in numbers, and the benefit of an annual face-to-face discussion of the problems belonging to the Bee-keepers' Union as now carried on.

Suppose that the North American should disband, and all of its members, with what little money they do possess, and their influence, should join the Union, and the latter should then change its constitution so that it would hold annual meetings at which all questions pertaining to bee culture could be discussed. We should then have the condition of things at which I am aiming. This may not be the best way to bring it about, and the suggestion is made more as an illustration than any thing else.

Personally, I have no interest in this matter; that is, I have no selfish personal ends in view. It seemed to me that the proposed union would be advantageous to the members of both organizations, and I have brought it up for discussion. It is quite likely that the question will be brought up at the coming meeting of the North American, and it would be well that it be most thoroughly discussed in the journals before that meeting takes place. The *Review* will be glad to receive communications on the subject—specially should we like to hear from members of the Union.

I must say, that, after looking over the whole situation, and studying it in all its bearings, I am in for supporting the amalgamation. I can't see *how* the workings of the Union would be hampered by being a part of the N. A. B. K. A., and the two organizations in one could be run much more economically.

Referring to Mr. Newman's able article, and his reference to the constitution which he drew up, as I have said before, the instrument seemed to be at the time an admirable one, and was, as I understand, modeled after a similar constitution that has been and is a magnificent success in England; but owing to the geographical distances, and other things peculiar to bee-keeping in this country, the experience of several years unquestionably proves, as Mr. Hutchinson intimates, that the constitution was inoperative in many of its features. For instance, it provided for affiliation by the payment of \$5.00 on the part of any society desiring to come into filial connection with the larger organization; and in return the latter was to grant the services of a judge, and distribute medals, besides several other minor benefits. But after some of the local associations had paid over the money for several years, and received no practical benefits, they "kicked," as they had a right to do. An effort was then made, which finally resulted in the securing of medals at a cost of about a hundred dollars to the North American—money that it could ill afford from the treasury.* But the "medal" business soon played out. Well, there were several other provisos in the constitution that were equally inoperative; in fact, it was practically impossible to carry them into effect as they were arranged by the framer, without more funds than it was possible to get from membership fees. Serious criticisms were offered, and GLEANINGS, among other journals, advocated striking out these features in order that the constitution might be *consistent with itself, in not offering what it could not furnish*.

It does not seem to me that the Union was ever "married" to the North American; and if it was, the ties of wedlock were so loose they did not hold. The truth of the matter, it seems to me, lies right here: Bee-keepers can not really afford two such organizations. Let the Union swallow up the North American, if need be; but let us boil them down into one; then let us have smaller initiation fees, conduct the one more economically, and run the membership up into the several hundreds.

If I am not very much out of the way, the increased membership of the Union very recently was due to the fact that bee-keepers thought, after the constitution was changed to take cognizance of adulteration and other matters, the Union would do something with this great problem of adulteration, and hence the new members. I do not quite agree that all the funds of the Union were raised for defense. The recent addition to membership brought with it an addition to the funds, and this was not so much for defense as for other matters.

* I was one of the executive board at the time, and thought the medals should be secured. I came in for my share of the blame; but I believed the constitution should be made consistent.—Ed.

If we expect large membership, and a power for good, so that, as Bro. York says, we may appeal to legislatures that will *hear*, it is my humble opinion that the Union should *branch out* in its line of work. The field of protection against unjust legislation is *too narrow*. The Union ought to take hold and *investigate* every case of alleged adulteration. It has *seemed* disinclined to take any such action. Again, it should, I think, keep a careful watch of the markets and of commission men. It should also have a watch-dog eye on swindlers who do occasionally creep into our ranks, and have in the past succeeded in carrying off hard-earned dollars from bee-keepers. I am not referring to adulterators, but to unscrupulous queen-breeders and supply-dealers—more especially the former, who have taken in large orders and then pocketed the money.

Last, but by no means least, it should and could fill the mission of the North American, in getting together the leading bee-keepers of the land for face-to-face and hand-to-hand conferences. It should grapple the great questions, and then with a large membership and a financial backing, be in a position to act and do something. The North American is not and has not been what it should be. The Union has had a brilliant past in the line of protection against unjust legislation. The need of such work is largely gone by, but there are newer and larger fields for action, and why not combine our two forces into one powerful one? GLEANINGS is for amalgamation, and, with the *Review*, it doesn't care whether the N. A. B. K. A. swallows the Union, or whether the swallowing is the other way. Let's combine our forces.

It has been whispered to me that some editor was after the General Managership of the Union, or such organization as might perhaps be perfected in the future by amalgamation or otherwise. So far as GLEANINGS is concerned, neither of its editors would accept the office under any consideration. I have already heard from the editors of three or four other leading bee-papers, and find that their position is ours exactly.

Since writing the foregoing, the following just at hand is in line with what I have written:

Although letter-writing is rather out of my line, I can hardly forbear saying a very few words on the proposed union of the North American and National Bee-keepers' Union. I sincerely hope the members of both associations will do all in their power to have them united, and put the dues down to 25 cts. a year, if possible. We ought to have in the National a membership of more thousands than we have hundreds to-day; and in order to get a respectable number on the roll, every one of the present members must do all in his power to induce others to join. Why not have the various associations all over the country discuss the matter of joining the National at their coming conventions? A good deal will depend on the support the bee-journals give the scheme. I want to see the National Union second to none in the United States. WM. RUSSELL.

Minnehaha Falls, Minn., July 23.

Surely goodness and mercy shall follow me all the days of my life, and I will dwell in the house of the Lord for ever.—PSALM 23:6.

Thursday, July 18, 1895, was anti-saloon day at Lakeside; and although Mr. Calvert was in Boston attending the annual meeting of the Y. P. S. C. E., and Ernest has been of late somewhat under the weather, I made arrangements for an absence of two days. At 8 o'clock I was on my wheel, and made the first twenty miles quite easily; but a wind that had been blowing all the time right in my face kept getting stronger and stronger, until it not only made whirlwinds of dust, but crowded back against me so hard that, by the time I reached friend Boardman's, I was pretty tired. I had promised Mrs. Root and the children to get on the cars, or hire somebody to carry me whenever I felt much fatigued. So I swung around into friend Boardman's dooryard. He and his helpers were out among his bees; and as he got sight of me he commenced:

"O Mr. Root! you are just the man we want to see, and you came at just exactly the time we want to see you."

"Look here, old friend, when you know what I want of you, may be you will not be so glad after all. I am tired out pushing my way against this steady wind, and I want you to get up those ponies and take me and my wheel to the electric-car line in time to catch the boat at Sandusky for Lakeside."

He said, "All right," and his boy started right out after the team. His good wife complained because I could not stay to have even an early supper; but while they were hitching up I was invited to look at his new outside beehive where he had just taken off the surplus honey from 80 colonies in the middle of the day, with the thermometer up to 94, and no disturbance of any sort. The escapes are fixed on the outside of the hive, so you have no machinery or fussing in order to provide a place for them in the usual way. And I want to tell you that friend Boardman has got a good crop of extra-nectar honey, notwithstanding the frost and the drouth, and the latter has been severe in his locality. I came pretty near running my wheel on to that fierce-looking chicken-hawk standing in the dooryard; and I was wondering why the thing did not show fight, or fly, until I remembered it was a *stuffed* hawk and not a live one. A rocking-chair in a shady porch made me think of Florida; but I began pretty soon twisting around in the direction of the pump. Oh what beautiful water! And there were harvest apples, mellow and juicy, that had just fallen from the trees; and I ate apples, drank water from the well, cupful after cupful, rested in the rocking-chair, and talked. Had I not worked my passage twenty miles against that wind I should not have dared to eat so many apples and drink so much water. But I knew by long experience that it would be all right. When we reached the electric car I was politely informed:

"No, sir, you can't bring that wheel on to this car, on any conditions whatever."

Of course, I had to submit—at least, the carman thought I submitted. I called to friend Boardman to take care of my wheel till my return; and then the conductor remembered that I could put my wheel on the freight-car just back of us. If he had said so at the outset it might have saved some needless arguing.

The conductor and I chatted very pleasantly, notwithstanding. The line from Norwalk to Sandusky passes through a very pretty country, and it is indeed a treat to ride over it. As the fare is only 30 cents, I suppose there is not much margin to allow them to bother with wheels. But let me offer these car-lines a suggestion: In going to Sandusky, we passed a double-decker. Just as many passengers can be carried in the upper deck as below; and, in fact, they all went up, or nearly all, from choice. Now, have a place on top of the ordinary cars to store wheels and other similar luggage. Make the passenger carry up his wheel, and bring it down again. Why, I could climb a ladder with my 18 lb. Rambler, without a bit of trouble.

When we reached Sandusky they said that the freight-car would not be in for a couple of hours, and there I was without my wheel. I could not wait, for there was to be a committee meeting that evening; and as one of the executive board it was quite desirable to have my presence. Our confab about the wheel and some other things had thrown them back, and the last steamer had gone for Lakeside. The car conductor and the steamboat agent both said there was no possible way for me to get to Lakeside that night. I asked if there were not some private boat that would take me over in time for the board meeting. But they said it would cost me twice as much as my lodging over night, and I could not get there then before ten o'clock. But I have not traveled all these years without learning something. Those fellows did not know how many times I had been told it was an *impossibility* to reach a certain point by a given time, nor how many times I got there, notwithstanding. It was 16 miles by rail; but I should have to walk over a dangerous long bridge and carry my wheel; and, come to think of it, I *hadn't* any wheel. I should have to wait two hours for it. In a few minutes, by dint of questioning and cross-questioning, I found a steamer going to Johnson's Island. The men on the steamer told me that at Johnson's Island I could get a sail-boat over to Peninsula, and then I should have to walk over two miles and a half—to *walk*, mind you, because I *hadn't* my wheel. I had decided to invest a two-dollar bill, if necessary, to make my destination that night. What do you suppose it cost? Just 15 cents on the steamer, and 25 cents more for a special sail-boat, or 40 cents in all.

My arrangements for the trip were just completed when I remembered that I should have no chance for supper, and I should sorely need some other refreshment than the harvest apples and pump water I had had at friend Boardman's. There were plenty of refreshment-stands, but they were all devoted to drinks and tobacco. They said they used to keep sandwiches, but they "didn't pay." The boat was to start in a few minutes. I ascertained there were sandwiches kept at a certain saloon near the boat-landing, down in a cellar or basement. I must take my long walk when both tired and hungry, or else go down to that saloon for sandwiches. I went down. It was so full of drunken rowdies, many of them young men and boys, that I could hardly get through, much less get the attention of a waiter. I thought I would rather go hungry, and beat a retreat. The boat was not quite ready to start, and I felt as though I *must* have a sandwich. I noticed a sign reading, "Ladies' Entrance." Surely I can find somebody down this way who will wait on me. A girl in the dining-room said the only place to get sandwiches was at the back end of the saloon. I told her the rest were so busy that I wished she would wait on me. She

volunteered, and we together went into the back end of the saloon. Thirty or forty men were yelling and cursing, some wanting to fight, some young boys just drunk enough to yell like savages, and all shrieking for *more drink*. The bar-tenders did not seem to have a bit of scruple in giving men on the verge of madness all the drink they could pay for. The girl shrank back, saying it was sometimes actually dangerous to go in there. "Surely goodness and mercy shall follow me," etc. Was it God's hand that led me where I was then standing? or was I out of place there among a drunken rabble in one of the underground dens of infamy in the city of Sandusky? The more I think of it, the more I feel satisfied it would be well if a delegation should go over from Lakeside and walk through these places as I walked through that one; and the reason why I have faith in Howard Russell is because he has been doing this very kind of work through almost all the towns and cities of the State of Ohio.

At Johnson's Island, for 25 cents four men with a boat having sails bigger than a barn took me across to Peninsula. The wind was good, and they said they could all sail over just as well as to do nothing. The same wind that hindered me so much on my wheel now carried me over the water (against the wind) like a bird. By the way, who is going to invent something for the wheel so that the wind may help instead of hindering us in riding against it?

It was almost dark when I started across the main land afoot. I lost my way by my eagerness, as usual, and had to go back. I reached the dense forest encircling Lakeside Grounds just as it was getting to be very dark. I could not see the path through the trees and bushes; but you remember when I climbed Wilson's Peak in the night I learned the trick of keeping in the trail by feeling with my toes. Riding the wheel, I now prefer for shoes the lightest kid gaiters. When I get off, by wiping off the dust with an old silk handkerchief I carry with me in my hip pocket, I can make myself quite presentable. You will remember how highly I spoke of Lakeside and all its appointments a year ago. As I came near the wicket-gate a man stood there with a lantern ready to examine my passport. It made me think of Pilgrim's Progress; but when I got clear up and reached my card through a hole in the gate, the gate-tender was puffing away at a big pipe. This did *not* remind me of the gate-keeper in the Pilgrim's Progress. The next morning at five o'clock I saw another man sweeping the auditorium, puffing away at a pipe. Why, what has got into the people of Lakeside? Can't they find a man to tend gate and act as janitor who does not use tobacco? May be these people come on only after dark, or very early in the morning. I did not see anybody smoking in the day time unless it was the agent for the steamboat and railway tickets. I was a little late at the Lakeside Hotel, but I met most of my temperance brethren, after all, and was ready for business next morning.

I must say a word more in praise of that Lakeside Hotel. Dear reader (perhaps I should have said dear *feminine* reader), just imagine a fine hotel, I should say equal to any in comfort, without a bar, without a cigar-stand, without anybody smoking a cigar, either inside or on any of its various porches; yes, and the most beautiful pure water to drink. There is a neat and tidy barber-shop, bath-room, and closets, and clean men and women in every sense of the word. They are getting good patronage, for every room was occupied, and I was obliged to sleep in one of the cottages. When I came to see the cottage assigned me,

however, I was not a bit sorry; and when I felt like taking a nap between the long sessions of the meeting, a kind Christian lady gave me one of the daintiest lounges to rest on, with vine-covered porches, and flowers in bloom, and shifting shadows all about me, as I closed my eyes to rest. Is it strange that I thought of the words of our text, "Surely goodness and mercy shall follow me all the days of my life"?

On the speaker's stand was an immense canvas on which was a map of the State of Ohio, showing the progress to date. The counties that had been canvassed, and would vote for the Haskell bill, and, furthermore, banish the saloons when the Haskell bill is passed, were painted in white; those not yet so canvassed, or those that refused to vote for the Haskell bill, etc., were shown in dark. Well, friend Russell and his organizers have already made Ohio look considerably speckled. Within the last few months some of the hardest counties have come into line, and some of them have been driving out saloons without even waiting for the Haskell bill. Prominent among these is the county of Defiance; and a minister by the name of Mills, working together with father Kincaid, a Catholic priest, are at the bottom of the work. A bright young Catholic lawyer, who gave us a soul-stirring address on temperance, has also been a mighty power. Dr. Lewis, of Cleveland, president of the recent Sunday-school convention, gave us a most admirable talk, explaining why the Sunday-school indorsed the Anti-saloon League. He repeated something from Parkhurst that brought vigorous cheers: "The wicked flee when no man pursueth." Parkhurst said that, while this is certainly true, it is also true that the wicked make a good deal "better time" when a good man is at their heels. Elder Belt was asked to tell why the presiding elders of the M. E. Church had so vehemently indorsed the Anti-saloon League. He said that, years ago, he had decided to join in with *any* thing that was against the saloon.

Judge West, of Logan Co., was asked how it was possible to keep such a beautiful city of 10,000 inhabitants as Bellefontaine entirely free from saloons, as well as Logan Co., of which Bellefontaine is the county-seat. The judge is old and infirm, and he has also lost his eyesight. On account of his age he sat down while he talked to us. He said he could remember the time when, by general agreement, the farmers for miles around used to come into Bellefontaine every Saturday afternoon and proceed around to the different saloons treating each other. He said these Saturday-afternoon fights kept the court-house full of business, and the jail full of inmates. Somebody asked him if banishing the saloons had made the town dull, and had driven business away. He admitted that it had been disastrous to one line of business. He said the city could not begin to support the crop of lawyers that it did in the "good old times;" but every other line of industry he thought would compare favorably with any other city of its size in Ohio or in any other State.

Space will not permit me to tell more of our grand meeting. The closing address was by Bishop Watterson, of Columbus. I never knew, until anti-saloon-day at Lakeside, that the Roman Catholics have a *total-abstinence* organization that has been in working order for more than 24 years; and I think it is surely true that, since other denominations, as well as Catholics, have joined hands, and since all political parties seem to promise to drop, for the time being, politics and every thing else, and as a unit wage war against *the saloon*, these great movements have made greater progress than was previously possible.

I stayed so long to hear Bishop Watterson through that I missed the boat again for Sandusky. In order to reach home at the appointed time Friday morning I must take the first train and go straight through. By telegraphing to have my wheel brought down to the depot I managed to get hold of it once more, and at fifteen minutes of four on Friday morning, July 19th, I was speeding on my way from the town of Berea, 18 miles due north from home. I reached home before breakfast was ready, and made the 18 miles without tasting food or drink. As the wind was at my back I made it easily; and I could have repeated my text at the head of this talk over every one of the 18 miles, and have it come honestly from the bottom of my heart.

My traveling-companions on the train from Lakeside to Berea were Mrs. Ellen J. Phinney and Mrs. Stephen Laird, State President of the N. P. W. C. T. U.; and the long pleasant talks and conferences we had together on temperance work I shall always remember. By the way, what a wonderful faith and inspiration and energy it gives in this Christian warfare, to feel that there are plenty of other dear friends and kindred spirits all over this land of ours! It may be somewhat of a speckled land, like the map we had up before us at Lakeside; but, God helping us, we are going to make the wicked flee, and that, too, with a good man after him every time; and who knows but there shall be also a good woman at the man's side?

FLORIDA TRAVELS.

Every thing in the way of fertilizers can be used on the Florida soil. Friend Keck told me that he saw an orange-grove where a pig-pen was made around three different orange-trees, situated in different parts of the orchard. These three trees bore great crops of fruit, away beyond any other trees in the orchard not so treated. I did not learn how many pigs were put into each pen, nor how large the pigs were; but the pens were just a cheap structure of rails; and it almost looks as if the pig business and the orange business might be run together, at least for a part of the year.

AVON PARK.

On the road to Avon Park, through the great piny woods, there were many interesting features. When I speak of the sand and the pine-trees, you must not get an idea that Florida is a desert waste, without water. On the contrary, our road sometimes lay right through the water for almost a quarter of a mile. The roadbed was almost as solid and hard under water as above it; and where the water is not more than a foot deep it often seems best to go through a shallow lake rather than around it. So you see it is not alone sand that hinders a wheelman. Another thing, these watery roads often crook around through a swamp full of luxuriant vegetation. If I were alone it would be a very difficult matter indeed for me to keep in the road right where it is under water; but most of the horses in that locality, if allowed to take their own way, would, by instinct or memory, follow along where other horses and wagons had gone before them. A stranger would be in a pretty bad fix in a Florida wilderness. "Stop and inquire," do you say? Well, I do not know whom you would inquire of un-

less it is the gophers; and you would not get a glimpse of even them unless you happened on them about daylight. You may ride miles and miles without seeing any house or any traces of human habitation.

Avon Park looked all the prettier as we emerged from the woods, after our long ride. It is located on the banks of one of the prettiest of Florida's pretty pure-water lakes. At the time of my visit it was about 20 miles from any railway station; but a narrow wooden-gauge track was being laid at the time, to connect Avon Park with the outer world. The hotel and boarding-house were beautiful structures, and every thing is arranged for the comfort of the guests. While there has been a great boom in real estate at this place there are a good many discontented people there now. They say it is all right, and a very pleasant place to live, but there is nothing for anybody to do. Well, there are people in almost every town in the whole United States saying this very thing. At first it did seem to me something of a question whether occupation could be found for all; but when friend Keck and I got up early in the morning and went out prospecting, I changed my views somewhat. Avon Park has suffered less from the frost than almost any other part of Florida I visited. On the south side of the lake, close by the water, at the residence of Rev. F. D. Rood, we found orange-trees with both foliage and blossoms. On other parts of the lake, however, the trees were more or less injured. The severe blizzard came from the northwest, and the protected spot seemed to be on the southeast. The warm water of the lake had tempered the blasts. Tomatoes were also growing thriftily and in full bloom. Of course, I became thirsty, and was told they got their drinking-water out of the lake. Just imagine the purest and nicest water you ever drank, glittering in the sunlight, with pure white sand for its bottom, ready to be dipped up by the cupful or by the pailful, as you choose. In the early morning it was very cool and refreshing. Various windmills around the lake bring the water where it is wanted, or take it from wells, put down wherever a well is needed. On the east side of the lake we visited some beautiful grounds that attracted my attention on account of the great cluster of giant bamboo—a sort of reed like our cane fish-poles, sending up shoots, in a single season, 50 feet high. We saw some that had been cut down, and were lying on the ground. They were as large around at the butt as a man's leg. Each section looked as if it were polished and varnished. In the center is an air-tight cavity like a keg or bottle. The inside is also nicely smoothed and polished. It is claimed that there is more strength, for the weight of material, in these bamboo sticks or timbers than in any thing else in the world, not excepting even iron and steel; and I believe it is generally conceded, especially since the day for wooden rims for bicycles, that a pound of the right kind of wood will bear a greater strain, and stand a greater concussion, without injury, than a pound of steel. It is thought that this giant bamboo is to have great value in the arts. It is only recently that it has been grown in Florida. It is now used as masts for vessels. The wood is very hard, but so light that, with these air-tight chambers, it floats on water like a life-preserver. The owner of the plantation was absent; but his good wife answered all his questions, and told us that this wonderful plant makes a growth in the summer time, of one foot a day. In fact, during the month of May, 1894, it averaged a foot every 24 hours. The green stalk looks something like an asparagus shoot, but, of course, ever so much larger. In the clump of bamboo

canes that we saw, there were perhaps 20 or 30 of these great trees, and 50 feet in height is all made in a single season's growth. After it attains such a height it just stands still, or only puts out side branches. I was told that, in other places in Florida, they have grown to the enormous height of 70 feet in a single season. Just imagine a forest-tree making its whole growth in one year! Of course, the plant has to have three or four years accumulating roots and branches before it makes this wonderful growth. Now tell us, will you? that the soil of Florida is so poor that nothing will grow. Florida is like a good many people, or, if you choose, like most people. They are capable of doing many wonderful things in their own line of work. But no man can excel in *every* thing. While we were discussing these queer properties of plants—the giant bamboo, the mammoth banana, or some name that sounds like mammoth—I became so curious that we were advised to call on the florist and nurseryman, Mr. H. G. Burnett. Here we found giant bamboos in great plenty at 50 cts. a plant, and friend Keck loaded one into his buggy. There were also many other wonderful tropical plants—the agave, for instance, that furnishes the rope material known as sisal hemp. This plant, not satisfied with furnishing *seeds* for perpetuating its species, actually grows little plants in place of seeds; and when they are well rooted and well started, it lets them drop on the ground. All you have to do is to gather them up and plant them in rows. Just think of a tree that produces cabbage-plants well rooted, and, you may say, almost transplanted. But they are not cabbage-plants, but sisal-plants. Well, I became so enthusiastic over these wonderful floral gifts (gifts from God) that I let fall some exclamation that attracted the attention of the nurseryman. When he expressed great joy and astonishment to see A. I. Root at his home, and admiring his handiwork, I asked him what he knew of A. I. Root.

"Why, bless your heart, doesn't GLEANINGS come to our house regularly? and haven't we followed you in your travels all these years? Little did I think it would be my privilege to see you away down here, looking over *my* work."

On the way home, near Crooked Lake it was my good fortune to see a real full-grown alligator sunning himself out on the bank. Yes, and there were two smaller ones lying near. Friend Keck said that, if we approached very cautiously, we might get very near them before they were disturbed; and then he made his mule go very slowly among the grass and weeds along the water's edge until I actually began to be afraid. How did he know that this great monster would not pounce down upon us and gobble us up, or smash us to pieces right there in the water, nearly two feet deep? Besides, I could not get over the idea that pretty soon we should strike a *swampy* place. It is true, we had *not* struck any as yet, but it looked exactly like places up in Ohio, where the horses and wagon would get in and never get out. We got up so near this great "gator" that I began to feel decidedly uncomfortable. Friend Keck, however, was as cool as a cucumber, and kept saying every minute that he would wake up and go off with a tremendous spurge. And so he did. One would scarcely think, from the looks of the great lazy monster, that he could possibly get up such a thrashing and splashing. When I began to insist that 'gators were dangerous, and that they sometimes eat people up, he said he knew of but one accident, and that that did not terminate fatally. It occurred near this very spot, as nearly as he could remember. Alligator skins used to be worth

about \$25.00 apiece—that is, the skins from the big ones (if it was not \$25.00 it was something less). The darkies are much given to 'gator-hunting. Well, a party of hunters came along here. A colored man, who was one of their helpers, saw an alligator on the bank; and having in mind the value of the beast he hastily cut a big club with which to pound him dead. I suppose he was somewhat excited, for he did not trim the limbs off from his club very well; but he thought it would answer, and so he slipped up cautiously, getting near enough the sleeping monster to give him a fearful whack on the back of the head. This 'gator did not prove to be so peaceable—at least, after such an invitation for a battle. He whirled around and grabbed the big end of the club in his teeth; then, according to alligator custom, he commenced rolling over and over, so as to bring his victim into the water, where he could drown him and then eat him at his leisure. The darkey was afraid of losing his prize, and so kept hold of his club, not noticing that the prongs he had left sticking out were getting entangled in his loose summer clothing; and as the process of winding went on, our colored friend was rolled up, and finally thrown off his feet. He yelled to the party of hunters, for help; and when they took in the situation they were convulsed with fits of laughter to see that the brute had rolled him over into the water, and he came near strangling before they could, by their united efforts, cut his clothing off from him, and get him away. Friend Keck said this was the nearest approach to killing a man that he ever knew an alligator to make. The 'gator I saw, he estimated was 15 feet long.

A little further on we came to a picnic-ground where there is a beautiful spring, or I should call it an artesian well. The water comes up in a great volume—sufficient, in fact, to make quite a little river. The temperature is just right for a comfortable bath; and if you feel like it you can swim, or at least attempt to swim, right down into the crater, "whence the healing waters flow." But the volume is so great that the water will throw you out as fast as you try to get near the opening. Turtles, fish of different sorts, and other reptiles, are being constantly thrown up by the boiling water. This was my first sight of the series of the wonderful springs of Florida. The water is all more or less impregnated with sulphureted hydrogen, like that of the artesian wells.

At Bartow I was obliged to bid my good friend Keck good-by, with whom I had passed so many pleasant hours, and start off once more for strangers and strange homes. An account of my trip from Punta Gorda to Fort Myers has already been given in my letter to the Sunday-school class, page 232, March 15.

At Fort Myers my eyes were greeted by green grass—grassy lawns and grassy roadways. My first point was toward a branch of the Florida experiment station, under the charge of W. A. Marsh. An excellent hotel furnished us with my first meal, consisting of fish, duck, and venison—surely a sufficient variety to suit any palate. Here again I saw the wonderful giant bamboo. At the experiment station they were testing crimson clover; agave, or sisal hemp, I have already mentioned; a great variety of grasses, millet, pineapples, etc.; and where anybody is inclined to say they can not raise even feed for the horses in Florida, they had better see what Prof. Marsh has already accomplished.

Somebody told me I must surely call upon Mr. W. P. Gardner. I went over in the evening, after my supper at the hotel. As I opened the gate, the perfume of flowers of various kinds gave evidence of the beauty of the place,

although it was too dark to see much but an indistinct mass of foliage. I rapped at the door, but nobody came. As said door was wide open, and a bright light shone beyond, I finally walked toward the light. A bright clean lantern was throwing its rays through an open veranda, but I did not see anybody. Finally the sound of human voices reached my ears from the house just beyond. Many of the best houses in Florida have a little building for cooking and dining, separate from the main building; and therefore during meal time the living-rooms are mostly deserted. After knocking at the door of this second building, which seemed to be a sort of summer-house out in a large garden, a very pleasant, nice-looking young lady informed me that her father had just gone over to have a talk with their pastor, Rev. J. M. Sweat. This was over in another part of the town; but I rather enjoyed the prospect of becoming acquainted with the pastor of the place, as well as with friend Gardner. Well, I found them; and, oh what a pleasant visit we did have for an hour or more, talking over matters social, industrial, and spiritual! The minister knew me by reputation, and friend Gardner used to preach in Medina Co. some forty years ago, and remembered me when I first commenced business here. He is an enthusiast in Florida fruits and flowers; and they told me on the steamboat that he actually raised so much fruit of different kinds in his garden that he had started a factory for canning guavas, and for making lemon and orange jelly. I have told you before about the delicious guavas. And now I want to say that his orange and lemon jellies are the finest I have ever tasted anywhere.

After we had looked over the garden by the light of the afore-mentioned lantern, viewed the rosebushes that had been in bloom every month in the year for ten years or more past, and tasted the delicious oranges while I smelled the perfume from the open blossoms, and after I had admired and asked questions about the wonderful plants and fruits, then he showed me their handsome canning-factory. Although no visitor was expected, it was as neat and tidy as a well-kept pantry. Their crop of guavas was so great, that, in order to keep them from spoiling, they had successfully canned them in great tin cans holding from five to ten gallons; then during the winter season these great cans were opened, and they made guava jelly, or put it in shape as the market called for it. I asked them how it was possible they learned to master the mysteries of the canning business so successfully. He told me they worked it out alone. I was afterward told that the bright, intelligent daughter whom I met was at the bottom of the nice-looking establishment and a successful industry. Mr. Gardner is a wonderful man; and that garden comes back to my memory as I write, as a veritable little garden of Eden, crammed with every thing luscious and entrancing to the eye, to say nothing of the perfume of the beautiful flowers. Fort Myers was the only place I visited in Florida that was practically unharmed by the freezes.

I reached Fort Myers toward night; and by the time I had looked over the branch of the experiment station, and got my supper, it was dark. The visit to the canning-factory and to friend Gardner's garden used up all of that evening. The boat on which I was to leave was to go out very early the next morning; and in order to see as much of Fort Myers as possible, I arose next morning before anybody else was stirring—at least, I did not see anybody. As I walked through the streets of the silent town, the cows got up lazily when they happened to be in my way; and I enjoyed seeing the sun

rise, and the bright-green grass sparkling with dewdrops, almost out in the middle of the streets. To tell the truth, I am afraid there is not very much business going on in the town of Fort Myers. I do not believe they have very many progressive and go-ahead men like W. P. Gardner. Perhaps the absence of frost-bitten vegetation was one thing that made me think Fort Myers was one of the prettiest spots in the whole of Florida. The soil seems to be exceedingly fertile. It is not altogether sandy. I do not know how much manure or fertilizer they use on their gardens; but there seemed to be a vigorous, luxuriant growth almost everywhere. On the outskirts of the town I passed by a garden that was so much ahead of any of the rest that I ventured near enough to look through the picket fence. A stuffed animal, that I guessed must be a wildcat, seemed to be standing sentinel among the vegetables. I thought of friend Boardman's chicken-hawk, and wondered if other people were using taxidermy in a similar way. Finally the door opened, and a lady looked out. I was so near by, I thought some apology might be needed for my apparent inquisitiveness; so I asked permission to look at their beautiful garden, and naturally made some inquiries about the ferocious-looking wildcat. When I happened to say that I had already described this method in our journal, she hastily interrupted me by an exclamation:

"Your journal! Why, it can not be possible that this is A. I. Root himself, away down here at Fort Myers?"

Then she came toward me with extended hand, while I inquired how it came that she knew of A. I. Root.

"Why, bless your heart, Mr. Root! haven't we taken GLEANINGS for years past? and haven't we in our wanderings followed you on its pages in your wanderings?"

Then she made haste to call the goodman of the house, and told him to hurry up and see A. I. Root himself, who had been right there looking through the pickets at their garden, before any of them had enterprise enough to get up. The stuffed wildcat was an idea they had taken from GLEANINGS; but the rabbits (I think it was the rabbits) had been helping themselves to their early cabbages and cauliflower, and they did not seem to have very much respect for GLEANINGS or his snarling catship either. I had just time to shake hands with Mr. and Mrs. David Hadley, and say "how d' do?" and "good-by" to the children, when it was time for the steamboat to leave. There may be objections to choosing Fort Myers as a place for a home; but I did not notice them unless it was a sort of apathy or indifference on the part of many of the inhabitants. I made some inquiries, early in the morning, for a clump of giant bamboo I was to find in the town; but a young man who was sweeping out before a grocery, who had lived there all his life, said he did not know of any giant bamboos, and had never heard of them. I afterward found them sending their tall spires away up above and over the hotel where I had stopped over night.

On my way back, in Charlotte Harbor I saw six boatloads of Florida phosphate, drawn by a tug. I should not omit to mention that at Fort Myers a very pretty residence was pointed out to me, belonging to Edison, of electrical fame; and, in fact, here and there throughout the whole State of Florida we frequently found residences built for noted men. As in the case of Edison, however, a good many of them rarely go down to even take a look at their places.

I don't think I can get along without GLEANINGS while we keep bees; so I want to subscribe for it three years. MRS. GEO. GIDDINGS, Laporte, Col.

CRIMSON CLOVER.

A great number of questions are constantly coming in, in regard to this new forage and honey plant, and we are selling large amounts of seed. In fact, a two-bushel bag is going out almost every day, and sometimes two in a day. I do not know what the consequence will be of sowing it too early. If it should blossom before winter, I suppose that would be the end of it, because the plant dies after blooming once. I presume, however, it is well to get as large a growth as possible, without running up to seed, the same as with spinach, and other plants that stand over winter. I would recommend, therefore, that it be put in all through the month of August, and perhaps through September also. In order to test it, we commenced sowing it first early in July, with buckwheat. This first sowing was up in a week, and now it has the second leaves on. It is very quick to germinate, and grows very rank and strong during this warm dry weather. We have had two good rains, though, since it was put in. Some succeed while others do not, in a locality as far north as this. Very likely, however, very much depends upon how it is sown, fertility of the ground, etc. It seems to be fully as hardy as red clover. Its great value to the farmer is, that it may be put in during August and September, wherever crops of any kind are taken off; and, more than that, it may be sown right among the standing corn, just after you cultivate it the last time. The corn shades it from the intense heat of the sun; and as soon as the corn is removed, the clover has the ground. We are sowing it to-day, July 29. We have just cultivated for the last time our extra-early Corey corn. We cultivated the ground before putting in the seed; and in order to get it well down during this hot dry weather we are going to run the cultivator through again after sowing.

There has been sufficient success, not only in Ohio, but even as far north as Michigan and York State, to warrant us in taking considerable pains to learn how to handle it. If it succeeds, you have a great lot of feed very early in the spring; and if you wish to enrich the ground for some future crop you have a great growth of clover to turn under. When it succeeds, this latter plan is probably the cheapest way of manuring your ground that has ever been devised. I say *manuring*, for a heavy growth of this clover, or, in fact, any clover, turned under just before planting your crop, is equivalent to a great many loads of the very best stable manure. Another thing, you do not get a great lot of weed seeds as where your manure is purchased.

PRICKLY LETTUCE, OR WILD LETTUCE.

A good deal has been said in our papers about this dangerous weed. But I am inclined to think a good deal more needs to be said. If you do not know it, it is a sort of milkweed, with bluish-green leaves, and yellow flowers the color of a dandelion, but rather more the shape of a thistle-blossom. The leaf is long and prickly. It does not quite surround the stalk, but there are a couple of little ears running opposite from the way the leaf points. Now when I tell you it will shoot up and go to seed quicker than almost any other plant you ever heard of, you will recognize it without trouble. This year, as usual our strawberry-beds were kept clean till

picking-time; then the weeds were allowed to grow until the last berries were picked, at which time the old beds were promptly turned under, as I have explained. Well, although there was not a prickly lettuce to be seen when we commenced picking berries, this weed was two feet high, and some of the stalks were sending seed flying out on the wind. I told one of our men that that patch of strawberries must positively, every plant, be plowed under before another day passed, and that the prickly lettuce ought not to stand for even one hour. Sometimes my friends complain that I do not explain fully just what I want or mean; but I surely did in the above. Would you not think so? Well, the man stopped his plowing between five and six, saying he did not suppose I would care if the weeds were left just one more day. Well, I thought best not to say anything, but I did care greatly. And we ought to care, all of us. Prickly lettuce should be stamped off from our farms and gardens, and we should not wait a single day or a single hour.

Three years ago the plant was unknown in the State of Ohio, and now I see it almost everywhere I go with my bicycle. Friend Boardman and I found it beside the road up in Huron Co.; and I am told it is now pretty much all over the State. Now, mind you, the dangerous part is the tremendous rapidity with which it grows in hot dry weather, and sends its seeds flying in the wind. The roots never live over like the Canada thistle. In fact, they do not need to. The remedy is to pull it up, or chop it off with a hoe just as soon as it is getting into blossom. That ends the business for each individual plant.

HOW TO HANDLE THE GAULT RASPBERRY.

The card of directions below was sent out with each package of plants shipped by me last spring. I believe Mr. Root did the same.

In unpacking, be careful not to injure the young, tender sprout. When the young canes attain the height of 6 or 10 inches, pinch out the top; this will encourage laterals.

Then, if you desire fruit, let them have their own way; but if you wish to propagate young plants, pinch off all the blossoms as fast as they appear. This treatment will cause them to throw out leaders which will root readily when covered with earth.

The second year, prune back the same as any black cap, and cut out all old canes as soon as through bearing.

It was my design to make it as clear as possible; yet I find that, in many cases, it has not been thoroughly understood. I have received many letters requesting further information in regard to propagating. The plants were not all sold to experienced nurserymen, but, on the contrary, a large proportion of them went into the hands of persons who were little practiced in the art of horticulture. To such this information may possibly be of benefit.

The most convenient time to pinch out the blossom is when it is a small round ball, about the size of a well-developed currant. At this stage it will roll out readily when pressed between the thumb and finger. I am not surprised that some mistakes should occur at this particular point, for I often find myself getting sadly behind in this matter by allowing great spikes of blossoms, and sometimes even berries, to form on the plants. Now, should this occur we must cut back beyond the last fruit-bud; for if we leave even one or two, the whole energy of the cane will go to ripen the berries, and not a single leader will appear.

It will be remembered that the production of fruit and roots depends upon different physiological principles; and the peculiarity of this variety of raspberries is that of its wonderful

J. W. DAY'S PLUM ORCHARD, CRYSTAL SPRINGS, MISS.

tendency to fruit-bearing. At one time when Mr. Root came to see my berries he asked me if I thought I had now learned about all there was to know about their treatment. I answered emphatically, "No," and added that I expected to learn a great many valuable lessons from him after he had a few years of experience. I have already received many important suggestions. They root at the end of the cane; and the time to tip them does not differ materially from that of other varieties of black caps. Ruggles, O., June 20. W. C. GAULT.

Perhaps some may inquire what time of year raspberry-tips are usually buried in order to get plants. I think we commenced burying the tips about the middle of September last season; and as more came out we kept covering them up through the greater part of October. We then had about two rows of Gault raspberries—about 50 plants in each row. One row had the blossom-shoots picked off as directed above, and the others were allowed to do as they pleased. Well, we did not discover very much if any difference in the amount of plants produced by the two rows. I think one reason for this is, that very rich creek-bottom land produces a great growth of wood and not very much fruit. If my reasoning is correct, a rich creek bottom is the best place to raise plants; but upland ground, and land not quite so heavily manured, would be a better place to raise berries. This is true of strawberries also. The creek bottom is the place to raise plants by the thousand, but not the best place for nice berries. We should be glad indeed to receive postal-card reports in regard to how our friends have succeeded and are succeeding with the Gault raspberry.

FRUIT-GROWING AT CRYSTAL SPRINGS, MISS.;
J. W. DAY SENDS US SOME ABUNDANCE
PLUMS, AND A PICTURE OF HIS
PLUM-ORCHARD.

Friend A. I. Root:—To-day I express to you a crate of the finest plums I have ever seen, and hope you will receive them in good shape; also one crate of tomatoes and a crate of magnolias and sweet-bay flowers, etc. They are for Mrs. Root and daughters and daughters-in-law.

I also send you a picture of my plum-orchard, taken last week. You will notice the three-story rack made to hold 36 water-buckets to the deck, or 108 in all. You will also notice the heavy tarpaulin rolled forward, and the driver sitting on it. It completely covers the frame when loaded. We use the five-inch-tire Michigan wagons. If you have a glass of the right kind, by looking close you may see the plums on the trees. They are all loaded. I have tried 63 varieties of plums here, and pronounce this one far in advance of them all. I guess it is the Abundance, or Sweet Botan.

I also send a clipping from an old friend of mine, written last week for his paper, the *Jonesboro Gazette*, Jonesboro, Ill.

Crystal Springs, Miss., June 24. J. W. DAY.

Our friends who have read the Tomato Book will recall the account of my visit to Crystal Springs—what I said about their peach-orchards, etc. If I recollect, friend Day showed me a single row of plum-trees a mile long. These plum-trees are now in full bearing. The picture gives you an idea of these. The road-way over the clean white sand in the foreground looks very much like friend Day's neighborhood. The plum-trees cover the ground so completely that it is a hard matter to distinguish the roads. The drooping branches,

borne down by their weight of fruit, is very suggestive, even though we do not clearly see the plums. One wonders how that wagon with its tier upon tier of buckets is ever going to get through such a dense thicket of trees. The buggy-top, a little ahead, suggests a roadway. I can not quite make out whether the children up among the tree-tops are picking plums, or whether it is another loaded wagon coming this way. I think I see a boy on foot with a paifull of plums in his hand, right back of the driver.

About the fruit that was sent us: Well, the plums were about the size of peaches, and certainly as luscious as any peaches I ever ate. Mrs. Root said we must not eat any just before going to bed, at the time the crate arrived. But I thought it would be almost uncourteous to our good friend Day if I did not bite into just one. Now, if any of you have ever tasted an Abundance or Botan plum like the one I tasted then, you will realize how utterly out of the question it was to put any portion of that plum away until morning. A little later I discovered some that were so much bruised they would probably spoil before morning. The more I thought of it, the more I felt certain of it. So I ate another and still another, and yet I did not feel satisfied. Oh, yes! we divided them around among the children and the "children-in-law," as friend Day had said. But if any one got sick, I have not heard of it. Now, this is indeed a great surprise to me. The *Rural New-Yorker* has told us about the tremendous quantities of plums that grow on one little Abundance tree; but I did not suppose they could be both so "abundant" and of such exquisite quality. Why, almost anybody would give a nickel for such a plum, just to show around and see people raise up their hands and make exclamations. We submit the following, from the newspaper mentioned:

They are now shipping 20 carloads a day. The tomatoes (Acme variety) are large and very fine. J. W. Day has the finest fruit-packing and shipping house in the country. It is 425 feet long and 40 feet wide, with a platform to the railroad track. In this building was stored box stuff for the fruit crop now arriving. Mr. Day has also put in an electric motor which propels fans over the packing-tables, which makes it cool and pleasant for the large number of packers employed. The tomatoes are carefully sorted, and packed with care. A carload of tomatoes and plums was shipped to Kansas City Saturday. Mr. Day is "right in it" on peaches this season. The 400-acre peach-farm, planted with great care by Parker Earle and J. W. Day, is now in bearing. The trees are not crowded with fruit, but there is enough for a good crop. Most of this fruit will be marketed next month. Thirty carloads is a conservative estimate of the crop. The finest sight upon this large fruit-farm is the four-acre orchard of Sweet Botan plums. The trees are loaded to the ground. These plums are delicious, and sell well. There will be 1000 bushels of them. Mr. Day has also a fine crop of tomatoes. Five hundred carloads of tomatoes will be shipped from his sheds this season. During the next month 150 people will be employed to handle his peach crop. There are other orchards here, and the fruit shipments from this station this season will be larger than ever before.

To-day was a big day for tomatoes, 22 carloads being shipped, and two left over for want of cars. The streets were thronged with wagons drawn by oxen, mules, and horses. The colored brother is going into the truck business largely, and it is feared that his carelessly packed stuff will knock the bottom out of the market.

EGYPTIAN ONIONS GOING TO SEED; LATHYRUS SILVESTRIS IN FLORIDA, ETC.

Mr. Root:—Is it usual for Egyptian onions to bear seed? I have some now in flower. In reference to the *lathyrus silvestris*, I have grown it for two seasons, and find nothing at all in it to compensate for the great trouble of

getting a stand here. It will not stand two weeks' drouth; and as for its honey, I have yet to see the first bee on it; and I doubt its being nearly as good a nitrogen-catcher as our common bush bean, Refugee, Best of All, or others of the same class, as I find far more nitrogen nodules on the bean than on the flat pea.

Crimson clover and sainfoin are far ahead for fodder, for soil-improvers, and for honey, the honey from the latter being equal to the best white clover, only a shade darker.

Wewahitchka, Fla., May 30. H. F. HART.

The Egyptian onions occasionally bear a few isolated flowers; but I have never known them to produce seed. By the way, this suggests the fact that there is a tremendous tendency in all the onion family to sport and mix up. Last season I said that the white Multipliers never produce seed-stalks. Now, we kept our Multipliers very carefully by themselves; but this season a dozen or two seed-stalks have run up. We might be tempted to think they would mix; but how could they mix when they never before produced seed at all, but just multiplied like potatoes? I am inclined to think the lathyrus is not suited for Florida; and, in fact, as a rule, neither are any of the clovers, if I am correct. I am glad to know that beans furnish nitrogen nodules as well as the pea and clover family. This I know, that beans flourish and thrive when the weather seems to be too dry or the ground too poor for almost any thing else.

ELECTROPOISE.

ELECTROPOISE \$25.00, AND NOT A CENT LESS
WHEN YOU BUY IT; BUT NOT EVEN 25
CTS. FOR IT WHEN YOU WANT TO
SELL IT BACK AGAIN.

If our readers will turn to page 536, July 1, they will notice that I there advised Leahy Beachy (a sister of Jacob) to ask the Electropoise people how much they would give her for the instrument back again, since it is comparatively new and almost unused. Here is the reply.

Mr. Jacob Beachy, Aurora, W. Va.:—

It is not our custom to take instruments back at any price. J. E. DUBOIS, Pres.

1122 Broadway, New York, June 20.

The above is the only sentence in the letter in regard to receiving it back again at some figure. Now, friends, is not this enough? There are still a few who insist that the Electropoise has virtue, and that possibly the manufacturers are doing an honest business, or think they are. Where an instrument is made to order, or a special machine is built for some particular person, cases may occur where it would be of no value to the makers; but this instrument is just such as they keep in stock, and furnish broadcast to whoever can be induced to buy them. When you want to buy, the price is \$25.00—not a cent less; you must even pay the express charges yourself; but when you want to sell the machine back again, in consequence of the death of the patient, as in the case above you are coolly informed that they "never take instruments back at any price." No wonder. It costs them in the first place only 50 cts., or even less; and probably their best retreat out of the corner they are in is to decline to purchase rather than offer 30 or 40 cts., the real cost of the thing to themselves. If there is anybody who now defends the Electropoise people, and claims they are Christian men, and doing an honest business, we should be glad to hear from them; or if there is a religious journal, or any other journal, that is accepting their advertisements, we would respectfully call their

attention to the above transaction. Let me explain again that the reason why the instrument was offered back was because the patient died while using it.

To explain the failure, the Electropoise people say the disease was probably, "organic." But they *knew* that in the first place; still they said they had "no doubt" they could "bring about a cure." Men have been justly hanged for being less directly implicated in murder than that. Can't the United States postal authorities put a stop to such rascality?

Many of our periodicals—in fact, our most respectable religious papers—have rejected Electropoise advertisements. Let me call attention to the *Union Signal*, which has right straight along refused to disgrace itself with Electropoise or any similar advertisement. This paper should have been mentioned in my former list. One of our subscribers wrote to the editor of the *Cumberland Presbyterian*, protesting in regard to Electropoise. Below is the significant reply:

Dear Brother:—In reply to your favor of the 11th inst., we would state that the Electropoise has been used by large numbers of people in Nashville and vicinity, including our most intelligent and sensible people. There are hundreds who believe they have been materially benefited by its use. I have used it myself, and it has seemed to benefit me. On the other hand, there are some people who believe that the benefit is purely imaginary, and that there is no efficacy in the Electropoise itself. Just how this is, is difficult to tell. We think that, through the imagination or otherwise, a great many people have been really benefited by its use. I suppose that certificates could be procured from thousands to the effect that it had been materially beneficial to them. This is about all the light on the subject which we are able to give you. JOHN M. GANT.

Nashville, Tenn., March 13.

There is a good deal of sound sense and wisdom in the above, after all. If people could be induced to pay \$25 for a horseshoe to be nailed up over the door, no doubt a great many would be helped through the imagination. I guess we are nearly all agreed on the above. But what sort of business is this for a *religious journal*, and a progressive one, to engage in? Can there be any fairness or honesty in taking money from poor hard-working *sick* people, fifty or even a *hundred times* the real value of the thing, even if it *does* cure through the imagination?

THINGS THAT MAY BE PLANTED AUGUST 1ST.

First and foremost for the bee-keeper, buckwheat and crimson clover, both on the same ground. One gives a honey crop this fall, and the other a crop of honey early next spring. In the way of garden seeds, almost every thing on our list on page 573 of our last issue, especially Egyptian and American Pearl onion-sets, and Multiplier onions. For prices of all, see page given above.

BEESEWAX DECLINED.

Until further notice we offer for average wax, delivered here, 22c cash, 25c trade. Market for wax in New York is quiet. We recently made a shipment at that point of three tons, and get about 5 to 6 cts. per lb. less than we paid there last March. Selling price of wax in small lots, till further notice, will be 29c average, or 31c for refined.

CALIFORNIA SAGE HONEY.

We have negotiated for a car of white-sage honey which we hope to have here ready to ship out on orders within the next two weeks. It may be a lit-

tle later before it arrives. We will take orders for shipment after arrival at 8½c per lb. for a single can; 8c per lb. in lots of 1 case of 2 cans, or more. Special prices quoted on large lots on application.

CHOICE COMB HONEY.

We have already handled quite a little new comb honey. We shall be pleased to hear from those not too far away who have some nice comb honey for sale, giving a description of it, and price asked. We are selling small lots of comb honey at 17c; 100-lb. lots at 16, and 200-lb. lots at 15c. The latter is our extreme price so far this season, and given for not less than a crate of nine 24-lb. cases.

CRIMSON-CLOVER SEED.

We still have a large stock of crimson clover on hand, and can probably supply all demands at the following low prices: Two-bushel sack, \$7.00; per bushel, \$3.60; half-bushel, \$1.90; peck, \$1.00; pound, 10 cts. If wanted by mail, add 10 cts. per lb. extra for postage and packing. We will send 3 lbs. by mail, postpaid, for 50 cts. From 8 to 15 lbs. of seed are needed per acre.

CHOICE CLOVER AND BASSWOOD EXTRACTED HONEY.

We have just secured from Vernon Burt, of this county, about a ton of very choice thick extracted honey, of excellent flavor. This we offer in new 6-lb. cans at 9c per lb. for single can; 8½c for a case of 2 cans; or 8c per lb. in lots of 2 cases or over. We shall have an outlet for more of the same kind, and shall be pleased to receive samples and offers from those having it for sale. We have an outlet also for some of a lower grade.

COMB FOUNDATION DECLINED.

On account of the declining price of beeswax it becomes necessary to decline the price of comb foundation. As the season for its use is practically over for this year, this decline will affect only the few sales from now till active season opens again, by which time it may be necessary to again change the price. For the present, however, and until further notice, the price will be 2c per lb. lower than in the table, as listed in our catalog, and the table of prices will then stand as follows:

Price per lb., in lots not less than
Sq. ft. per lb. 1 lb 10 25 50

Heavy brood foundat'n.	4 to 5	45	44	43	42
Medium "	5 to 6	45	44	43	42
Light "	7 to 8	48	47	46	45
Thin surplus "	10	55	54	53	52

TEN NEW ENGLAND BLOSSOMS AND THEIR INSECT VISITORS.

The above is the title of a very pretty new book sent us by Houghton, Mifflin & Co., Boston. It is the work of our well-known friend Clarence M. Weed, and contains some of the most beautiful half-tone engravings of flowering plants and other things that ever graced the pages of any book since the world began. Please remember that is the opinion of A. I. Root, who may not have seen all the books in the world. The typography and the whole make-up of the book is a thing of beauty indeed. It consists, as you will judge from the title, of an account of both flowers and insects, including our honey bees and their relations to the floral world. The book might well grace the parlor-table of any bee-keeper. The book contains 142 pages, neatly bound in cloth. Price, postpaid, \$1.25.

BOOK OF FRAUDS AND OVERCHARGES.

The above is the title of a book by E. W. Cole, of Melbourne, Australia. A part of it is taken up with Dr. Wilford Hall's water-cure swindle. The book contains the whole of Dr. Hall's wonderful story; it also contains the entire matter of a book published by Dr. Juke, 60 years before. Dr. Juke's book is so wonderfully like Dr. Hall's little pamphlet that one can hardly escape the conclusion that Wilford Hall had the book before him when he wrote about his wonderful discovery. The latter part of the book is given to the publication of secrets regarding patent-medicine frauds, including cures for drunkenness, etc. On one of the fly-leaves in the last of the book we find a prospectus of another work, entitled, "Advice of Ten Doctors."

No. 2 of the ten seems to be your humble servant, A. I. Root; but as friend Cole has put me in company with Dr. Kellogg, Dr. Trall, and other eminent professors and M. D.'s, I suppose I ought not to find fault. I presume likely it is a collection of what I have written in regard to doctoring without medicine, etc. I appreciate the compliment, dear friends; but I never want to sail under false colors; so please remember that I am neither a doctor nor a minister, nor any thing but a common layman who loves humanity, body and soul. The price of the book is, I think, 35 cents.

Friend Cole puts a strong emphasis on the fact that Dr. Hall claims emphatically that he was "the first of all earth's teeming millions to inject more than a pint of water into a human being." Dr. Juke, in his book, 60 years before, however, says, "With this apparatus I was enabled, by refilling it, to throw up 14 pints of water, which proves its very great capability." So if Dr. Hall really discovered any thing it was just what Dr. Juke had put in practice, and published with great emphasis, 60 years before.

KIND WORDS FROM OUR CUSTOMERS.

The freight you sent me reached its destination all right. I was highly pleased with it. You need no other advertisement than to show your goods. You may expect a larger order from me soon.

Lawn, Texas, May 23.

JOHN LACKY.

Accept my thanks for the beautiful lot of sections you have sent me. They can not be excelled in smoothness, evenness, and fineness of finish. An order for several thousand more will follow this.

Martinsburg, W. Va., June 3. WILL THATCHER.

THE NEW CRANE SMOKER.

The new Crane smoker is a "dandy"—gives a tremendous volume of smoke, is very easy to load with planer shavings, which I use, holds its fire well, and responds at once after standing unused for a long time.

Troy, N. Y., May 31.

LEVI DE FREEST.

Dear Friend Root:—GLEANINGS is at hand just now. Before I forget it, let me tell you that, whenever your bicycle-chain breaks or flies off while going down hill, all that you have to do is to grasp the fore part of your front wheel between your feet and thus improvise the most efficient kind of brake.

Knoxville, Tenn., June 20.

ADRIAN GETAZ.

[To the above kind suggestion, E. R. R. appends a footnote as follows:

"Yes, sir; you ought to learn this foot-brake act. It may save your life."

I have already learned, on wheels having a foot-rest brake, in the manner described; but at the time mentioned it was just all I could do to keep my seat, to say nothing of manipulating my toes so as to break the speed. However, I am going to practice further on the subject.

A. I. R.

"The Southland Queen."

Send \$1.00 for the Southland Queen. Edited by the Atchley family. Plain, practical, and all fresh bee matter. Jennie Atchley will begin a bee-keeping school in June 15th No. All that wish lessons, come in. A steam bee-hive factory, Root's goods, Dadant's foundation. Send for free catalog and sample journal.

THE JENNIE ATCHLEY CO.,
Beeville, Bee Co., Texas.

Stingless Bees! See page 525, GLEANINGS, June, 1895.
H. Alley, Wenham, Mass.

THE FOUR SEASONS RUNNERLESS STRAWBERRY.
Grown from French seed. Fifty or sixty fruit crowns form and fruit on each plant between May and November. Berries small and shuckless. Plants 10c each.
A. T. GOLDSBOROUGH,
Wesley Heights, Washington, D. C.

Advantages of Bee-Escapes.

No sweat steals down the heated cheeks and aching back of the bee-keeper as the result of standing in the hot sun puffing, blowing, smoking, and brushing bees; no time is wasted in these disagreeable operations; and no stings received in resentment of such treatment: the honey is secured free from black or even the taint of smoke; the cappings are not injured by the gnawings of bees; and robbers stand no show whatever. If there are any broken burr-combs they are cleaned up by the bees *inside* the hive, before the honey is removed. **Leading Bee-keepers use the Porter Escape**, and say that without a trial it is impossible to realize the amount of vexatious, annoying, disagreeable work that it saves. The cost is only 20 cts. each, or \$2.25 per doz. As in the past, this escape is manufactured by the Porters, but The A. I. Root Co. has secured control of the sale for this country. Order of your dealer or of

IF YOU WANT BEES

That will just "roll" in the honey, try **Moore's Strain of Italians**, the result of 16 years' careful breeding.

Dr. H. B. Lung, Harrodsburg, Ky., says: "I have had the pleasure of seeing many fine strains of bees, yet I have never seen such industrious, energetic bees. I must express my admiration for your success as a bee-propagator."

Warranted queens, 80c each; 3 for \$2.00. Select warranted queens, \$1.00 each. Safe arrival and satisfaction guaranteed.

Those who have never dealt with me, I refer to A. I. Root, who has purchased of me 808 queens. Circular free.

J. P. MOORE, Morgan, Pendleton Co., Ky.

Beeville, Bee Co., Texas.

Golden or Leather Queens

From the Queen Specialist. . . .

Golden queens from Duvall's best; dark leather queens bred from the celebrated Manum stock (queen mother selected and tested by him).

My drones are all bred from a colony that wintered successfully on summer stand without protection, bees gentle and excellent workers.

This colony is the result of seven direct crosses of golden Italians, selecting the most desirable for breeders each spring, regardless of color.

Nearly every queen mated with selected drones as there are no bees within several miles of my yard. Duvall strain will produce nearly all 5-banded bees, Manum stock 3-banded.

Price 75 cts. each. Safe arrival guaranteed, and shipped by return mail if desired.

FREE COINAGE—16 to 1.

It is claimed by some that this would give us a double self-regulating standard, while others believe it would simply change the standard from one metal to another. There is no such uncertainty in regard to the **fence standard**. The Coiled Spring remains the universal unapproachable self-regulator for farm, railroad, and park purposes. If **ELASTICITY** can do for the currency what it has done for The Page, there'll be no opposition.

PAGE WOVEN WIRE FENCE CO., Adrian, Mich

QUEENS!

Good,
Better,
Best.

The latter is what I am trying to furnish, with what success a long string of testimonials might startle you, as the season is now prime for the rearing of queens, and in competition with some other reliable dealers I will furnish to any new customer 2 Golden Queens for \$1.00; a straight five-banded breeder, \$3.00. Address

W. H. LAWS, Lavaca, Ark.

For Sale!

A Hawkeye camera, recommended by E. R. Root, of whom I purchased it 3 years ago, with instruction-book, plate holders, and plates, at \$37.00. Will sell for \$32.00. Has scarcely been used since, and has an excellent lens which alone cost over \$30.00. Also a World typewriter, in good order, for \$3.00; a copying-press, nearly new, for \$3.50; a Victor safe (new), list price \$60—will sell for \$45.00. A 4 H. P. portable engine and boiler, in good order, \$115.00; a rotary pump for lifting water for irrigating, in good order, for \$25.00; a counter-shaft, new, price \$10.00; also a lot of Dovetailed beehives, combs, foundation, and fixtures. Particulars on application. CHRISTIAN WECKESSER, Sanborn, N. Y.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—We are receiving new comb and extracted. New white comb, 14; extracted, white, 6½@7; dark, 4½@5. Demand good. Beeswax, 22.
HAMBLIN & BEARSS,
 Aug. 8. Kansas City, Mo.

PHILADELPHIA.—*Honey.*—The honey market is about the same as last quotations. Trade has been somewhat quiet, with only a small demand since the 1st of July. We look for a rather dull market until fall. We quote new-crop extracted, 5½@6½, in bulk; comb, 11@14, according to quality. Beeswax, 25@27.
WM. A. SELSER,
 Aug. 9. No. 10 Vine St., Philadelphia, Pa.

CINCINNATI.—*Honey.*—Demand is lively for new extracted and comb honey, all old honey being cleaned out. Arrivals are fair, but insufficient for the demand. Comb honey brings 14 and 15 for choice white. Extracted, 4@7. Demand is good for beeswax at 20@25 for good to choice yellow.
CHAS. F. MUTH & SON,
 Aug. 7. Cincinnati, O.

CHICAGO.—*Honey.*—New comb is selling at 15c, and so far has sold upon arrival. We quote amber to dark at 8@10@12, according to merit of same. Extracted white, in cans, 6½@7; dark grades, 5½@6. In barrels, about half a cent less, as is usual at this season; later there is little difference in price. Beeswax, 25@27.
R. A. BURNETT & CO.,
 Aug. 7. 163 So. Water St., Chicago, Ill.

BUFFALO.—*Honey.*—No new honey as yet in the market; still a slight amount of old on hand. No doubt fancy new comb would open up well at 14, possibly 15; choice, 11@12; other grades in proportion. Extracted honey would be very slow sale here. Beeswax, 25@30.
BATTERSON & CO.,
 Aug. 8. Buffalo, N. Y.

DETROIT.—*Honey.*—Best white comb honey (new), 13@14; supply light; no dark to quote. Extracted, 6@7. Beeswax dull, 23@25.
M. H. HUNT,
 Aug. 8. Bell Branch, Mich.

ALBANY.—*Honey.*—We received quite a few consignments of new comb honey. The quality is only fair, but it is selling off quite freely at 12@13. No. 1 would bring better prices. We have also received some extracted put up in glass jars which finds quite a ready sale—price depends on size, style, etc.
CHAS. McCULLOCH & CO.,
 Aug. 7. Albany, N. Y.

CLEVELAND.—*Honey.*—We received our first shipment of new honey, and sold it at 15c per lb.—fancy white, in 1-lb. sections. White extracted is scarce at 8c. Beeswax, 26@28.
WILLIAMS BROS.,
 Aug. 7. 80 & 82 Broadway, Cleveland, O.

BOSTON.—*Honey.*—The demand for honey is very light. Have had a few small lots of new comb which we quote at 16c. Extracted in fair demand at 5@6, with light supply. A small lot of new California extracted sold at 6½.
E. E. BLAKE & CO.,
 Aug. 8. Boston, Mass.

MINNEAPOLIS.—*Honey.*—Our honey market is in fine condition. Fresh arrivals of new honey are selling at 16@20, according to quality and condition. Strictly fancy white honey is jobbing in lots of five and ten cases at 18c; small way, 20.
J. A. SHEA & CO.,
 Aug. 3. Minneapolis, Minn.

DENVER.—*Honey.*—Our market is being well filled up with new honey, especially comb. There seems to be very little demand for extracted. We have been receiving quite a number of shipments for which we have been getting 10@11c. Our trade requires a No. 1 white grade, suitable for putting in our cartons. Extracted, No. 1 white, in 60-lb. cans (2 in a case), 6c. Beeswax, 25.
R. K. & J. C. FRISBEE,
 Aug. 9. Denver, Col.

KANSAS CITY.—*Honey.*—The receipts of new comb honey are very light, and demand fair. We quote new 1-lb. comb, No. 1 white, 14@15; No. 2, 12@13; No. 1 amber, 12@13; No. 2, 10@11; extracted, white, 6@6½; amber, 5@6; dark, 4@4½. Beeswax, 20@21.
C. C. CLEMONS & CO.,
 Aug. 8. Kansas City, Mo.

CHICAGO.—*Honey.*—We are having inquiries for comb honey, and expect our first receipts of fancy white to sell at 15c; our No. 1 white will bring 14c—no trouble to sell fancy honey. Second quality sells from 10 to 13, depending on condition. White extracted sells from 6@7, depending on flavor; dark extracted, 5@6.
S. T. FISH & CO.,
 July 30. 189 South Water St., Chicago, Ill.

FOR SALE.—Two carloads of prime mountain comb honey in 24-lb. glass-front shipping cases; labeled goods, full weight, 1-lb sections; 10 cts. per lb. on the tracks here. **A. B. MELLEEN,** Acton, Cal.

FOR SALE.—White comb honey, 14 and 16c. on board cars. **G. R. ROUTHAWN,** Menallen, Pa.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty. **J. P. IVY,**
 Secretary Bee-keepers' Association,
 Phoenix, Maricopa Co., Arizona.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c.

CONVENTION NOTICES.

There will be a meeting of the Southeastern Bee-keepers' Association in Fort Scott, Kan., Sept. 19th, 1895. All are cordially invited.
J. C. BALCH, Sec., Bronson, Kan.

The annual meeting of the Northern Illinois Bee-keepers' Association will be held at the residence of O. Taylor, in Harlem, Ill., on Tuesday, Aug. 20, 1895.
B. KENNEDY, Sec., New Milford, Ill.

The Southwestern Wisconsin Bee-keepers' Association will hold its next meeting at Platteville, Wis., Oct. 8th and 9th, 1895. Come all! Don't get discouraged even if we haven't got a crop of honey. We shall have a good time at Platteville just the same. Bring your wives and daughters with you. Many interesting subjects will be discussed.
M. M. RICE, Sec., Boscobel, Wis.

Wants or Exchange Department.

WANTED.—To exchange 200 colonies of bees for any thing useful on plantation.
ANTHONY OPP, Helena, Ark.

WANTED.—To exchange several good safety bicycles. Honey wanted. Send sample.
J. A. GREEN, Ottawa, Ill.

WANTED.—To exchange 26-in. planer, power scroll saw, all iron; tenoner, and mortiser, for portable sawmill, or other wood-working machinery. Will give a bargain for cash.
GEO. RALL, Frenchville, Trempe Co., Wis.

WANTED.—To exchange foundation-mills and honey-extractors for honey or wax.
I. J. STRINGHAM, 105 Park Place, New York.

WHAT have you to exchange for a 200-egg size Invincible Hatcher?
G. J. STURM, Mt. Erie, Ill.

WANTED.—To buy 2 tons extracted white-clover honey, in 60-lb. tins.
GEO. G. WILLARD, 270 Pearl St., Cleveland, O.

WANTED.—To exchange latest improved Marvel magic lantern, best quality (cost \$45), also 100 choice views, for honey, beeswax, or offers.
E. E. SLINGERLAND, Troy, Pa.

WANTED.—To exchange bees in new 8-frame L. hives for a ladies' bicycle.
W. D. SOPER, Jackson, Mich.

WANTED.—To exchange some fine St. Bernard pups. I have some extra fine ones and will exchange for honey, or any thing useful. I want a bicycle. My pups are from registered stock. Write at once.
SCOTT BRILLHART, Millwood, Knox Co., Ohio.

WANTED.—To exchange about 4 bushels of Egyptian onion-sets, strawberry, blackberry, and raspberry-plants, for foundation, sections, or offers.
D. NOBLE, Clintonville, Wis.

WANTED.—To correspond with all who have honey to sell.
F. N. JOHNSON, Box 137, Knoxville, Knox Co., Ill.

WANTED.—To exchange English Beagle hound female, in whelp, for repeating-rifle, extracted honey, or offers.

Queens, Either 3 or 5 Banded.

60c each; 6 for \$3.25. These low prices are to induce you to try them. Catalog free.

CHAS. H. THIES, Steeleville, Ill.

Don't Be Afraid to Buy

those fine, tested Italian queens I am offering for 65 cents, just because I offer them so cheap. It is not on account of any inferiority that I sell them so cheap, but because I replace, every year, all of my queens in over one hundred colonies, run for honey production, and what I get for the old queens I consider just like finding. A good many are sold already, but there is a fine lot on hand yet, equal to any in the country. A few mismatched ones at 30 cts. each.

T. H. KLOER, Terre Haute, Ind.

Please mention this paper.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they wish to dispose of, we will insert notices as below, first insertion free of charge. After the first, 10 cents per line. We do this because there is hardly value enough in these queens to pay for buying them up and keeping them in stock, and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

About ten mismatched Italian queens for sale at 30 cents each, or 4 for \$1.00. They are all nice queens, young and prolific.

W. F. STUART, Box 415, Ottawa, Kan.

Twenty or twenty-five extra choice mismatched queens, reared this season. Imported and Doolittle queen mothers, 30 cents each, or 12 for \$3.00.

L. H. ROBEY, Worthington, W. Va.

A Letter

From A. Norton, of Monterey, California, reads as follows: "The queen that you sent me arrived in fine condition in twelve days from the time I ordered her. (It takes six days for mail to go from here to California.) Twelve hours later she was introduced, and in twelve more was laying. I thank you for your promptness and for the beauty, and excellence of the queen." From neighboring States I frequently receive reports of queens being received and introduced within three days from the time the order was sent. I not only advertise to send queens by return mail, but I do do it, and sell tested queens of this year's rearing for only \$1.00 each, or six for \$5.00. One queen and the REVIEW for \$1.50.

W. Z. HUTCHINSON, Flint, Michigan.

Proof Beyond Doubt.

A customer, looking over my 400 hives in home apiary, said, "Where are your bees? Mine were flying all around thick this morning." I said, "Just stop; look down at any hive." He was amazed. They were just pouring in thick with their heavy loads. This proves two things—they can't be excelled as workers, and quiet.

I opened several hives. He had no veil; was in the apiary $\frac{1}{2}$ of an hour; was not bothered once. Try them. Untested guaranteed queens, 75c. Send for wholesale price list.

Wm. A. Selser,
Wyncote, Pa.

The Bottom is Out!

STRAY STRAWS

FROM DR. C. C. MILLER.

I'M FOR THE UNION of the Union with the North American. [That's right.—Ed.]

THE KANUCKS seem to be getting things in good shape for the Toronto convention.

CRIMSON CLOVER when in bloom is pretty enough to afford a bed of it room in a flower-garden.

THE *Revue Internationale* contains an account of a successful case of transferring bees in midwinter.

I'VE SEEN TWO BEES working on sweet clover, with pollen on their legs. It didn't look brown, like white-clover pollen, but was a sort of faded yellow.

"THE TALENT of success is nothing more than doing what you can do well, and doing well whatever you do—without a thought of fame."—Longfellow.

THE PLAN for determining adulteration in wax by means of carbonate of soda is denounced in *Revue* as worthless. [What is the plan, in brief? I'd like to try it.—Ed.]

A REPORT on p. 596 says bees in Florida have made two tons of honey. If one colony has done that, it's big; but if it means all the bees in the State, it's rather poor.

IF CRIMSON CLOVER will not stand the winter so far north as this, perhaps a spring sowing would mature a crop of seed to pay expense and give a crop of honey extra.

THAT'S A GOOD IDEA of Wm. Russell, p. 599. Make the annual payment to the North American 25 cts., and then give full value for that money to all members who stay at home. [I agree with you.—Ed.]

THE *Canadian B. J.* says you can extract dark and light honey separately, even if in the same comb. Hold up to the light; uncap and extract the light patches, then the dark. I should think that would work nicely if too much brood has not been raised in the comb.

IT SEEMS that we can count 5000 bees in a pound when not loaded, and 3000 when loaded. That means a bee carries a load equal to two-thirds of its own weight. [These would be fairly correct for round numbers.—Ed.]

A HINT is hinted at in *Progressive*, that I'd better be giving a little grain instead of so much straw. Now look here; the sign-board over this shanty says "straw;" and when you make application here, straw's what you'll get.

DURING LINDEN BLOOM I watched bees on trees close by, and never saw but two bees during the season gathering pollen. I always supposed they got much pollen from linden. Can it be that they gather less pollen from trees close by?

BETTER PUT a couple more ciphers in that first column, p. 585, and make 7 or 8 lbs. of bees count 21,000 or 24,000, instead of one-tenth that many. [Dear me! how could I have let such a mistake pass? We'll let this serve as a correction.—Ed.]

STRICTLY FANCY new comb honey is quoted in the honey column, page 580, at 12 and 13; and one firm says, "We anticipate a price of 14 to 15." I anticipate they'll anticipate a higher price than that before they're flooded with consignments this year.

"MUTUAL ADMIRATION" societies are getting some hard knocks nowadays. For one, I'm a hearty believer in such societies. If I can't find a man in this world who has something in him to admire, and if no one in all this world can find a single thing in me to admire, then I want to get out of this world right away, quick.

DID YOU EVER know a queen to lay an egg in a cell containing pollen in a normal colony? I have seen such a case, and I wonder whether such eggs hatch out. [I have known of drone-laying queens, and laying (or fertile) workers laying on top of pollen, but never a normal queen that laid eggs that would produce worker brood.—Ed.]

THE PROBLEM of controlling fertilization of queens seems to have no one working on it nowadays. Can't some one dream out a solution? So far the solutions seem to have been nothing

but dreams, like the one sent out, under government authority, as a positive success. [There is a method, and it is practical. See article by James Wood, in this issue.—Ed.]

NO WONDER that poor fellow at the head of "Reports Discouraging," p. 596, looks discouraged when you set him on his head. [You were sent the first sheet off the press. The mistake was rectified before many had been run off. That page was all made over after its first reading, and the heading was misplaced by accident.—Ed.]

THE VAST DISTANCES of this country have always been given as the reason for the small membership of the N. A. B. K. A. Don't be fooled by that any longer. It has to do with the attendance but not with the membership. If we were as bright as the stolid Germans we could get members to belong, even if they never attended. [You're right.—Ed.]

HOW MANY BEES in a strong colony? J. L. Hyde, p. 585, sets it at 25,000; but surely that's very low. A 9-lb. swarm contains 27,000; and before the colony swarmed it contained many more. Years ago Donhoff figured that 63,000 was the maximum number in one colony. I suspect it may go beyond that; but I don't know. [I think Hyde is nearer right, because his weights agree with what I secured a number of years ago. Estimates are liable to be too high, any way.—Ed.]

OUR AUGITE STOVE-MATS are losing their power, after long and faithful service. It seems ridiculous to think they can be replaced for five cents each; but they would be replaced, even if they cost ten times that. If your wife has none, surprise her by your thoughtfulness in getting something that will save many an hour of watching and stirring over a hot stove. Tell her she can put a dish of milk or oatmeal on a hot fire for an hour without burning, and she'll not believe you till she tries it.

PARALYSIS. Here's a cure given by James Carmac, in *Progressive*: "Remove several frames from the center of the hive, with the one with the queen (if she is valuable), as a drop kills as if scorched with a hot iron. Sprinkle the bottom-board with a tablespoonful of the mixture—equal parts of benzine and turpentine—replace the frames, and close the hive." After this treatment, used three times, his bees recovered; but he is wise enough not to feel sure that it was the treatment that cured. [Bee-paralysis so often goes off of itself without treatment that I don't believe the benzine mixture had any thing to do with the matter.—Ed.]

A FRIEND is considering the advisability of using chemical fertilizers for strawberry-beds in preference to barnyard manure at 75 cents a load on the ground. He thinks freedom from weed-seeds may make up for difference in cost.

What does A. I. think? [This has often been suggested; and in the East, on sandy soils, I am told they raise nice strawberries by the aid of chemical fertilizers. In our locality, however, I have never been able to find any chemical fertilizer at any price that would take the place of stable manure at all on strawberries. To tell the truth, they hardly show any results. Of course, guano tells every time; but this can not be called a chemical fertilizer. Application of ashes has also given some excellent results, after having manured the ground heavily with stable manure previously.—A. I. R.]

TEMPERAMENT OF BEES.

HOW FAR SHOULD WE TAKE IT INTO ACCOUNT?

By S. E. Miller.

Do we not often make mistakes in managing our bees, in thinking that one colony should act and do just like another colony under the same conditions? Do we make due allowance for the difference in disposition or temperament of our numerous colonies? A colony of bees must, to a certain extent, be considered as an individual so far as the mind—or, perhaps, more properly, their instinct—goes. We all know that a colony works under a single impulse—that is, what is the motive of a few is the motive of the entire colony; so we must consider a colony as having a single mind. All work together for the common good of the colony. Certainly, when a bee darts from the hive that we are working over, and dips us over the eye, we are glad that the entire colony is not seized with the same impulse at the same moment; nevertheless, there is a controlling passion which seems to have the same influence over the entire colony at the same time.

Let us look for a moment at the higher order of animals and see the difference in dispositions. Take, for an example, man. Among thousands you will not find two exactly alike in temperament. Then take horses, with which some of us are accustomed to work almost every day. One will be wild, vicious, and hard to manage; while another, having the same treatment, may be docile and gentle.

Let us go still lower in the scale of the animal kingdom, and notice a flock of poultry. Here is a brood of fowls that were hatched out in the field or forest. One hen laid the eggs, hatched them, and reared the chicks up until they were large enough to scratch for themselves. We should suppose that this brood would be very much alike in disposition when they arrive at maturity; but such is not the case. Some are apt to be shy while others are tame; and in

many ways we may notice a variation in their dispositions.

The above may seem foreign to bees; but I have alluded to it to show that there is a variation in temperament among the same species in the animal kingdom.

Let us now go to the apiary. There are two colonies, apparently just alike. We know they are very nearly alike so far as strength and the amount of stores they have is concerned; and the one colony might be expected to do just as the other does, yet the one colony is storing honey quite rapidly while the other one is doing very little. Here are two colonies very much alike, that we gave supers to at the same time. The one has the super half filled, and is working nicely, while the other has not even begun. Here is a colony that builds very straight even combs, while some of the others build crooked, bulged, and uneven combs, although their conditions are very much alike. Over there is a colony that will not accept a queen, but will kill queens as fast as you introduce them, and insist upon rearing one of their own so long as there is a shadow of a chance—that is, as long as they have any unsealed larvæ to rear one from. No matter if the larva is several days too old, they insist on having one of their own rearing. Their nearest neighbor may be a colony that will accept a queen by merely taking away their own and giving them another, say twenty-four hours later. One colony will cast a swarm before the hive is more than two-thirds full of brood and honey, while others will wait several days after their hive is chock full.

To what, then, can we attribute this difference? Where all are in the same apiary it can not be laid at the door of location, for the resources of one colony are available alike to all that are of sufficient strength to send a full working force to the field.

We are forced to the conclusion that there is a vast difference in the dispositions of different colonies, or, perhaps, we might say, a particular individuality peculiar to each colony. When we consider, then, the different climates to which bees are subjected, the difference in the flora, and the difference in the time of year that the main honey crop is gathered in different parts of the world, is it to be wondered at that all bees in all places do not act alike? Is it surprising that a hive and a particular system of management that work well in one part of the country are failures in another and widely separated location? Is it strange that we have not, can not at present, and, perhaps, never will, all agree on any particular size or shape of hive or any particular system of management?

I could continue further in this line; but as my article is becoming long I will try to come to the point which I started to bring out. Can we not, perhaps by studying the nature and particular characteristics of each colony, be enabled to manage them with greater success and

profit? Would it not often be better to yield to the particular whims of a colony, or at least compromise matters, than to undertake to make them do altogether according to our ways of thinking, when our way may be in direct opposition to what is the height of their ambition or desire?

Probably there are few if any bee-keepers, who use modern hives, that have not at some time tried to prevent a colony from swarming, and by so doing caused them to sulk until the honey-harvest was past, and thus obtained nothing from a colony that, by proper management (that is, by humoring them in their desire to multiply, and replenish the earth), might have been induced to store considerable surplus honey.

In my mind there is no doubt that some colonies will build comb much more readily than others. To put such at storing honey to be extracted, and those that are disinclined to build comb at work in the sections, would certainly be a mistake; and yet how many of us pay any attention to this in putting on the surplus receptacles?

The above is a subject which I do not recollect having seen discussed in any of the bee-papers, and I feel that I have made only a feeble effort; but if it should call forth thought and advice from some of the leading lights in bee culture, it may be of use to the fraternity.

Bluffton, Mo.

[This article is clear and logical, and the writer draws some very practical conclusions. One in particular is, yielding to the whims of particular colonies.—ED.]

WHY SHOULD THERE BE SUCH A VARIETY OF OPINIONS?

BEEES ON STRAWBERRY-BLOSSOMS; HAVE THEY BEEN KNOWN TO INJURE THE FRUIT ITSELF? HONEY-DEW AS A WINTER FEED FOR OUTDOORS AND INDOORS, AND THE DIFFERENCE IN RESULTS.

By W. S. Fultz.

In the controversy just now going on in the various bee and agricultural journals, it is asserted by some that bees do not work on strawberries while in bloom; and by others that they do. While I never knew the bees to work on strawberry bloom at any time during 22 years' experience as a fruit-grower, yet I am not prepared to assert that they do not so work. In my location bees usually find honey from other sources just at the time strawberries are in bloom; and as there is little or no honey in strawberry bloom they are not going to leave better pasture to forage on that which is poorer.

In other localities it is probable that, just at the time the strawberries are blooming, there is no other source from which the bees can get a living, and they then resort to the strawberries. When this country was first settled, and

the Mormons were at Nauvoo, Ill., they sent some of their elders to preach, and set stakes in this part of Zion, and many of these elders were very illiterate, considering the work they were expected to do. On one occasion two of them had an appointment to preach in a schoolhouse near here; and when about to announce his text, the one who was to preach stated that he had forgotten to bring his Bible, but that his text would be found in the book of Exodus, and read like this: "And Bezaleel made the ark."

"Hold on!" exclaimed the other elder, "it was Noah who built the ark; everybody knows that."

"Brother," said the first elder, "I believe I know what I am about, and I say it was Bezaleel who made the ark; and if some good brother or sister has a Bible here we will soon settle our dispute."

A Bible was procured from a house near by, and the first elder turned to the 37th chapter of Exodus, and read: "And Bezaleel made the ark of shittim wood," etc. Explanations were in order, and it was apparent that the two elders had different arks in their minds, and that a little explanation by elder No. 1 would have made a controversy impossible. If we were to take a wider view of many of the disputes that arise we should often see that there is really no occasion for a dispute.

In the *American Bee Journal* for July 18, Mr. J. A. Nash, of Monroe, Ia., gives an account of getting a great deal of honey-dew honey a few years ago, and he blames that honey for the destruction of his bees during the following winter and spring. As all bee-keepers in this part of Iowa had an experience with that kind of honey at the time, and as some of us wintered our bees successfully on it, I felt inclined to dispute his statement that it was the honey-dew that was so detrimental to his bees; but when I come to consider some of the facts I am inclined to think he is right. He wintered his bees in a cellar, and I wintered mine in chaff hives on their summer stands; and it is possible that my bees were enabled to take a purifying flight during the winter, without being unnecessarily disturbed, while his were not, and that may have made all the difference between success and failure.

During the fall of 1871 our bees here gathered much of that honey-dew honey, and at that time we knew nothing of chaff hives, and resorted to cellar wintering, and almost all of the bees in the country died.

If at any time before our strawberries ripened this year any one had asserted that bees worked on ripe strawberries I should have said that it was a mistake, as I had never, in my long experience as a fruit grower, seen a single bee on a ripe strawberry; but this year my bees attacked what few strawberries had escaped the frost of May 13th, with a fury that was ir-

resistible. As only myself and boys, who were used to handling bees, did the picking, they did not drive us out of the patch as Mr. Wm. C. Ashby says of himself in the *American Bee Journal*; but they did ruin fully half of the crop; and as berries were scarce and high-priced, the loss was a serious one. My loss by bees working on strawberries and raspberries this year will aggregate more than all the bees and honey that I have sold from an average of 30 stands of bees in ten years; and yet there are plenty of writers on bee culture who will assert that bees never do any damage to fruit of any kind.

Bees, like human beings, will try to live on any thing that gives a promise of appeasing hunger when starvation drives them to it; and bee-keepers certainly owe it to horticulturists that they feed their bees and keep them at home at times when starvation drives them to destroy fruit.

When picking strawberries and raspberries I noticed that, during the morning and until about 9 o'clock, when the bees were knocked off the berries they were quite lively, and either flew away or else to another berry; but after about 9 o'clock, if knocked off they fell to the ground and acted as if intoxicated. Did the berry-juice have that effect on them? No berry-juice, so far as I could ascertain, was carried to the hives.

Our blackberries were a complete failure. From two acres I did not get a single box. The drouth used up what the frost did not kill. This week we have had five inches of rainfall, and the drouth is broken.

Muscatine, Ia., July 20.

[I think we can not question that the bees do at times work on strawberry-blossoms; neither can we question that they may, in very rare instances, attack the fruit itself while on the vines. I do not remember to have read a report of their having done so before; and I should say the case you mention is most unusual; still, we must not conceal the facts. I don't have much sympathy with that class of bee-keepers and bee-journal editors who insist, in spite of all the facts to the contrary, that bees will not attack ripe fruit. Careful and conscientious bee-keepers who observe matters closely know that they do at times when there is a great dearth of nectar from natural sources. The cases, however, are not frequent; but to deny them all is to do more harm than good.—Ed.]

NO HONEY AT DR. MILLER'S.

THE QUESTION OF BROOD CHAMBERS, LARGE OR SMALL, DISCUSSED.

By Emma Wilson.

We are disappointed in more ways than one in not having any honey crop this year, as there were so many experiments that we wanted to try. They had to be postponed last year on account of the failure, and it is rather discouraging to know that they will have to go

another year for the same reason. One of the things we were very anxious to decide upon was the size of hive we want. We were trying some with 11 frames, some with half-stories under the eight-frame hives, and some with two full stories, or 16 frames. For myself I feel pretty sure I want the frames all in one story. Two stories makes too much lifting. I don't know that Dr. Miller agrees with me in this.

I am afraid the eight-frame hive is not large enough; in fact, I'm sure eight frames are not enough for some of our colonies in the spring. As I said in my last article, some of our colonies had as many as eleven frames of brood. But I believe eight frames are enough during the honey-harvest. I should dreadfully hate to give up the eight-frame hive. It is nice to handle, and makes the hauling to out-apiaries far easier. But then, when I think of the big crops of honey we used to have with the larger hive, I wonder if it's the eight-frame hive that's the trouble, or have the seasons changed? and are we never to have any more honey crops? I do not think the size of hive has made any difference with our crop this year or last, for there has been no honey to be had, either for large or small colonies.

We certainly did not have the swarming with the larger hives that we have had with the eight-frame hives. But there may be another reason for that. We always, during the honey-harvest, left a small opening at the back of the hive, for upward ventilation, and a current of air was constantly passing through the hive, that may have helped a good deal to prevent swarming. We have not been giving this ventilation since we have had the eight-frame hive in use. The bees will not finish up the sections quite so quickly at the back end when the ventilation is given, and for that reason we have discarded it. But I'm not sure but it's a good thing to have the ventilation nevertheless.

For the last two or three years we have been placing small blocks at the corners under some of our hives, raising them $\frac{3}{4}$ of an inch from the bottom-board, leaving an opening all round, and I believe it's a good thing. It gives them more air, and it may help to prevent swarming—not that we're troubled with swarms at present. We've not had any this year, and are not likely to have. I'm not fond of swarming bees, but I would even put up with the swarms if the honey would only accompany them.

There is one thing I don't like about our latest eight-frame hives, and that is the dummy. It is made of two pieces, and some of them warp and bulge at the center. Dr. Miller says the trouble is they are made of basswood.

Oh, yes! another thing I don't like. The hive is not wide enough to suit me. I want a little more room to get the dummy out. The way I generally do now is to pry out a frame first and then remove the dummy, or else leave the dummy in. I am speaking now of the hives with

the first Hoffman frames with the wide ends to the top-bars and the end-bars with square edges. These have been in use some time, and the bee-glue has accumulated about a sixteenth of an inch. Of course, that makes about half an inch less room in the hive. We ordered fifty hives last year having narrow ends to top-bars and V edges to end-bars. They are all made with frames wired ready for use, but we have not as yet succeeded in getting bees into many of them. They may be better. We have not had much chance to try them.

Marengo, Ill.

[You would not have trouble with the dummies providing you had in use the latest Hoffman frames. Those that you refer to were the very first we put out, several years ago, and we sold only a very few of them, as we saw at once it would be necessary to change them. Sometimes I remove the dummy first, and sometimes the brood-frame, but more often the former. The dummy—or, as we call it, the division-board, is now made so as to have a projection that facilitates very greatly its removal. I very often pry over the entire set of frames clear to one side. This gives ample room for the removal of the division-board; then I split the brood-nest perpendicularly at any point desired, and remove a frame if I wish to.—ED.]

RAMBLE 138.

IN THE GOLD-MINES.

By Rambler.

ESIDES the bee-keeping profession, Mr. Schaeffle is a mining expert, and he bears the U. S. Government's say-so as proof of it. He has had much experience in this science in Colorado as well as in

California. He has traveled over a good share of Northern California in the mining interests; and, always having an eye open to the bee-keeping interests, he can give much interesting information in relation to the honey-flora of this portion of the State. He claims that the counties of Lassen, Modoc, and Shasta, are practically undeveloped so far as bee-keeping is concerned; and, owing to the large area covered with sage, the quality and yields would equal the more favored South. Thus far, however, the cost of transportation from those wilds would hardly warrant trying the experiment of bee culture on a large scale.

In the early mining days, Murphy and all of these towns in Calaveras Co. were surrounded by placer diggings. The surface has been torn and upheaved with the pick and the spade, and the best of the soil has been sent down stream with the washings, while millions of dollars in golden nuggets have been taken from the pan and the rocker. In some places the surface of the country is honeycombed with

miners' claims; and where they sank their shafts (or we might call them wells) to bed-rock, as a miners' claim is 16 feet square, these holes became numerous. But the palmy mining days have become a story of the past; and only debris, and holes caved in and hidden with brush show where the men toiled for gold. Now and then an old miner strikes a little "pay dirt," as he terms it, and, by the side of a little stream of water, works out with his rocker a paltry two bits a day, or even less.

Quartz-mining has taken the place of all other methods; and to even start one of these mines requires as much of a fortune as would satisfy an ordinary bee-keeper. The largest of these mines are located in Angels. The Utica mine gives employment to some 600 men, taking out \$250,000 per month. The mill operates 180 stamps; each stamp weighs 850 lbs.; and

But another sound comes to the ears. The poor sewing-woman in the garret, the laboring man on the street, raise the earnest cry, "Silver, silver; good silver." The farmer and the bee-keeper sing the refrain, "Root of good, root of good; silver, silver." The church-bells chime the silvery tones, and a day of rest, day of rest. The silver shout grows louder; the relentless rattle of gold for the rich has its day; the ballot brings peace and good will, and the thundering stamps now merrily shout, "Silver and gold! silver and gold!"

Mr. Schaeffle touched me on the shoulder, and the dream vanished. We went forward with our inspection of the mill; but "silver and gold, a day of rest, peace and good will," echo in my ears even unto this day.

The gold is liberated by crushing, and is caught in a quicksilver battery. This yields

A QUARTZ MINE AND MINERS.

its fall of five inches, to crush the ore, is about every two seconds. The reader may judge that the 180 stamps, all in one building, make a deafening roar—the earth trembles. These stamps continue their harsh music for 365 days in the year.

Amid the roar of the mill I fell into a sort of trance; and as I listened to the water gurgling under the stamps it seemed to say, "No Sunday here, no Sunday here." The ore, as it rattled continuously toward the stamp, said, "Root of evil, root of evil." The stamp harshly answered, "It is gold, it is gold." Out of the din and thunder of the stamp-mill the mind flashes to the far-off cities, and finds a connecting link in the soulless railroad corporations, and the din of railroad trains answers to the mine, "No Sunday here, no Sunday here." The rattle of traffic on the street echoes "Root of evil, root of evil." In the stock exchange the frenzied calls of the gamblers, the raps of the gavel, and the madness of the hour, re-echo, "It is gold, it is gold."

about 65 to 75 per cent of the gold. Formerly this was all that could be saved; but now the sulphurets, in which the waste gold went off, are saved in a large building called the chlorination-works. The process is quite complicated, and now 95 per cent of the gold is saved from the ore.

Mr. Schaeffle being upon sort o' fraternal terms with the superintendent, we were allowed to descend into the mine. A large bucket of boiler iron (that is what we should call it, but in miner parlance it is called a skep) is operated by a hoisting-engine and a wire rope that runs over pulleys in a tower fully 60 feet in height. The superintendent had gotten this drop on us, and ordered Mr. Wilder and myself into the skep, while he and Mr. Schaeffle clung to the rope and stood on the edge of the skep. We were provided with candles; but the miners have little lamps on the front of their hats. This allows a free use of the hands. The signal is given—a tap of a gong—and down we go—down, down. The shaft is 1000 feet deep, and

we stop at the 900-foot station. Here we crawled out of our skep and explored the underground world. Mr. S. and the superintendent kept up a running talk about shutes, stopes, veins, high grade and low grade, etc. The stretch of landscape is not very extensive in a mine. Tunnels run in various directions, and at different elevations from the main shaft; and here we found the miners at work with the aforesaid lamps on their hats. The drills were churning away with rapidity, operated by compressed air. After working the drill it escaped and kept a supply of fresh air in the

regulated cellar. Instead of the potato-barrels and apple-bins they have a good substitute in now and then a few boxes of dynamite; and I wish to say to my Prohibition brethren, that I here found a place where prohibition is a success. The owners of the mine prohibit smoking, and the use of any spirituous liquors. They think dynamite is quite elevating enough for all intents and purposes.

We returned to daylight via the wire-rope-and-skep route, and with Bro. Schaeffle we returned to Murphy. This town also has a hole of its own in the ground, made by nature;

CALIFORNIA REDWOODS.

mine. Some of the side tunnels were several hundred feet in the rock; and as we explored, the little cars of ore would squeeze past us. The men seemed to be perfectly contented, and quiet. I don't know whether they sing much in a gold-mine or not; but probably not, as their music has not much chance to expand. Bro. Wilder and I supposed we could see gold sticking out in chunks; but we saw not a sign of it. It is so fine in this rock that a magnifying-glass will scarcely reveal it.

Although we are down 900 feet, we have the same feeling that we experience in a well-

or, in other words, Calaveras Cave is considered a wonder. Mr. S. led us into this, which is 300 feet deep. The chambers were not large; but the stalactites and various formations were interesting. In the chrysanthemum-room we found beautiful white formations, in shape resembling the above flower. A thin curtain-shaped stalactite, when its various folds were struck with a stick, gave forth musical sounds, and a skillful operator could ring out a melody. This was called the "organ." This hole in the ground is also, in a certain sense, a gold-mine, for the owner of it exacts tribute from visitors,

and his income is profitable, for thousands of people visit the cave.

Fifteen miles from Murphy are the wonderful sequoia, or big trees. Our route was up the San Antonio, a fine trout-stream; and whenever we saw a deep pool in the tangle of rocks and trees, we had in mind our aforetime fellow-traveler Pryal, and his passion for the hook and line, and—bites.

Travelers are many times disappointed over some famous feature of nature, from the fact that their imagination has pictured the feature away beyond the reality; but in our case the giant sequoia were fully up to expectations; and the longer we lingered in the grove, the more majestic they appeared.

There are 90 trees in this grove, and they bear the names of generals and other noted men of the world. Ten of these trees are each over 30 feet in diameter, and over 325 feet in height. A few of these monarchs of the forest, having served their day and generation, have succumbed to the wear and tear of time and tempest, and are now prone upon the ground; and, though fallen, they are objects of wonder.

We spent one night camped under their tall forms; and when we departed we felt as though we had seen another of the grand features in nature, and a feature especially characteristic of this wonderful country.

We returned to Murphy again, and sojourned several days under the protecting care of Bro. Schaeffle. I found that Calaveras Co., though not so prolific in schoolma'ams as Humboldt Co., was nevertheless well supplied. One would suppose that my traveling companion had lost his entire heart in Humboldt Co., and that it would be many years before it would be entirely healed; but he had wonderful recuperative powers; and here we were, barely two weeks from those dashing Humboldt damsels, and other fair schoolma'ams were attracting his undivided attention. It was the wielder of the birch in the town of Angel that threatened to wreck us this time. The name "Angel," in contrast to Humboldt, as a prefix to schoolma'am, does really appeal to the imagination; and when Humboldt can so easily be construed into humbug, I could hardly blame my partner for his preference. I tried to show my friend the error of his ways, and our argument ran upon the qualities that constitute a terrestrial angel, with the following result:

"An angel, Bro. Wilder, of earthly frame, is fair,

Sylph-like, with flowing golden hair.

An angel! how ridiculous it sounds

Applied to schoolma'ams of quite two hundred pounds."

"Not so," quoth Bro. Wilder, with a little bit of ire;

"A red-haired girl I never did admire;

But a black-eyed schoolma'am, worthy to be won,

Is every whit an angel, e'en if she weighs a ton."

This condition of mind was a danger-signal not to be slighted. The ponies were harnessed, and we traveled rapidly out of Calaveras Co.; and that night, many miles away in Tuolumne Co., we camped in the shadow of the Golden-nugget apiary.

HOW THE MATING OF QUEENS CAN BE CONTROLLED.

QUEENS, AS A RULE, NOT MATED AT A DISTANCE FROM THE APIARY; AN INTERESTING EXPERIMENT.

By James Wood.

If this question is to be construed so as to apply to a certain individual drone, I answer no. If, as I understand it, we wish the queens mated to drones from a single colony, I answer yes. I know very well that I am stating what is not generally believed; but I am going to give you the facts just as I have observed them the past four seasons.

Let me first say that I am located at least three miles from any bees except my own. I have practically given up breeding five-banded queens; therefore I feel more free to give these facts than heretofore, as I did not wish to use the reading-columns to draw attention to what I had to sell.

In the spring of 1892 I purchased my first five-banded queen. I at once introduced her to a full colony, and began to rear queens, all of which mated with the three-banded drones, as no others were yet hatched. I tested a great many of these queens. They wintered well, and proved great workers; but now to the point I wish to prove. Their progeny showed nothing but bright three-banded bees. Not one queen in a dozen would show any five-banded bees; and what did, there was less than one per cent. Well, this mother-queen (my first five-bander) was given several frames of drone comb, and in the mean time I purchased another five-banded breeding-queen, and bred all my queens from her the remainder of the season. As soon as the drones began to fly from queen No. 1 I placed the drone-traps on every hive in my yard except this one. I now had drones in but one colony, that could fly. Now, nearly every queen that I raised after the traps were put on produced from 25 to 50 per cent five-banded bees, and a few, 95 to 100 per cent.

"But," says some one, "this proves nothing definite, as you used another queen to rear your queens that produced the five-banded workers."

Let us pass by 1893 and '94, which I might mention as seasons of experimenting, and come to 1895. I now have, at the beginning of the

season, drones from several three-banded colonies, and no others. I raise about 15 queens from my five-banded stock, and again only three-banded workers appear from their progeny, as in 1892. Later I trapped off the drones and allow only the golden drones to fly from a single colony as in 1892; and out of over sixty queens bred from the same mother there are only two that do not produce a large per cent of five-banded bees—a much larger per cent than in 1892. The two remaining queens produce some black bees, but mostly three-banded.

There are about a dozen colonies of black bees in very large box hives about six miles from here, and there is a good colony of drones in each one—that is, if the amount could be counted as a colony, and undoubtedly a thousand drones to my one.

I mention this to show you that queens do not mate to any great extent five or six miles away. There were a few colonies of black bees within a mile of me ten years ago, when I first began rearing queens. I had more trouble with them than I do with this horde of drones now, six miles away, although at that time I had a plenty of drones in nearly 40 hives. I might give many more facts that I have observed along this line, but I think I have shown that queens may be mated with selected drones from any desired colony, provided you are located far enough away from other bee-keepers. I could not give these facts had it not been for the five-banded bees. I will give them credit for giving new light on this subject, if nothing more.

North Prescott, Mass., Aug. 1.

[I have obtained permission to use a portion of a private letter accompanying this, that confirms, among many other letters that I am not at liberty to use, my position on the five-banded queens. Here it is.—Ed.]

THE REARING OF FIVE-BANDERS DISCONTINUED, AND WHY.

I have given up breeding the golden queens to any extent. You may be surprised, after the letter of recommendation I sent you from a customer in Canada. I have since called for reports from my customers who had purchased large numbers of me; also some of our best honey-producers. In substance, here is what one very successful honey-producer in Florida says:

"The 54 queens are beautiful, and produce handsomer bees than any others I have. I purchased several of Doolittle and Case last season. Your bees are very gentle, and, as a rule, good workers; but the two three-banded queens beat them all. The five-banders are bad about robbing, and I want no more of them. I dislike to say any thing against your bees, but I know you want the truth. D. R. KEYES.

"Wewahitchka, Fla."

You see, friend Root, that the two three-banded queens gave better satisfaction than any of

the other 52 golden queens. Last year your cry against them was, "They were cross." I never had any complaint on that score. I have always used gentle stock for breeding both drones and queens. This is the only complaint I have that they are robbers. But Mr. Keyes produces a great deal of extracted honey. I can see no difference in them in any respect in my locality, with the exception that they may not winter quite as well; but of this last I am not sure, as I have had some colonies winter splendidly. Mr. Keyes further said he would buy of me if I would breed three-banded bees. Customers in the North think they do not come out as strong in the spring as other bees. J. W.

HEDDON HIVE THE BEST SOLUTION OF THE HIVE QUESTION.

NO TROUBLE ABOUT THE QUEEN LAYING IN
TWO HIVE-SECTIONS AT A TIME; WHY MC-
INTYRE'S DOUBLE BROOD-CHAMBERS
WERE NOT A SUCCESS.

By J. E. Hand.

Mr. Root:—I see by the July 15th number of GLEANINGS the hive discussion has taken a new departure. Heretofore, I believe, the discussion has been confined chiefly to the Langstroth frame; and the difference in opinion has been about the number of such frames to be used in a hive to give the best results; and as I firmly believe the size and shape of brood-frame has even more to do with our success or failure in the production of surplus honey than the number of frames used, this question is of more importance to the honey-producer than the other. I believe that much good will result from this interchanging of ideas so long as the right spirit prevails; and as long as these discussions are carried on by practical honey-producers whose opinions are unbiased by any pecuniary interests, and who are desirous only of arriving at the size and shape of frame best adapted to the successful production of surplus honey, there can be no danger in this direction; and while I believe it has been pretty fully demonstrated that the size of brood-chamber can be governed only by the location, time, and duration of the honey-flow, I am not so ready to admit that location has any bearing on this question of the shape of said brood-chamber.

I believe it is a fact generally acknowledged, that, other things being equal, a swarm of bees will store as much honey in one hive as in any other; but it is not so readily conceded that all hives are equally well adapted to the successful storage of *surplus* honey in the very best shape for market; and more especially is this true in the production of comb honey.

Friend Dayton struck the key-note of the whole business on page 550, July 15, when he said the measurements of the Gallup hive were found exceedingly unsuitable for the adoption of the standard section. I was compelled to

adopt the Langstroth measurements. Aye, there's the rub; and so long as the $4\frac{1}{4}$ section continues to be the standard, just so long will the shape of the Langstroth form of hive make it so much better adapted to the successful use of this section than any square or deep frame hive. It will require better arguments than have yet been produced to induce very many practical honey-producers to change from the L. to any square-frame hive. On the contrary, I am firmly of the opinion that the tendency of the times is in the opposite direction. I believe about all the advocates of the square hive claim is that they winter better and build up faster in the spring. While this is doubtless true when run on the let-alone principle, as many so-called bee-keepers manage their bees, yet it is a demonstrated fact that, with proper care and management, the L. hive will generally have its working force ready for the harvest when it comes, and that is all that is necessary. Too large a swarm in early spring is not desirable, and never does as well when the harvest comes.

I believe the majority of bee-keepers, like friend Dayton, have found out that the L. hive form is best adapted to the use of the standard section; yet is there not room for more improvement in the same direction? or, in other words, is there not some system of management that will preserve the form of the L. hive for surplus, and yet give us more perfect control of our bees, and thereby enable us to secure something of a crop of surplus, even in poor seasons which seem to be so common with most of us? Has not this need been supplied by the advent of the horizontally divisible brood-chamber hive?

While there are locations so good that almost any kind of hive will give a fair crop of surplus, yet there are very many locations so poor that it is only by the very best system of management, and strictest attention to every detail connected with the business, that any thing like a decent crop of honey can be secured. In such a location as this it has been my lot to be placed as a honey-producer, and for several years as a specialist, depending on the production of honey for food and clothing for wife and the little ones, and therefore I must have a hive and system that will give me perfect control of my bees at all times—one that will give me all the white honey where I want it, and that is in the sections. I have never invented a hive, but have carefully tested every hive of any note that has come before the public for the past twenty years; and the divisible-brood-chamber hive is the only one that has ever given me perfect control of my bees. With this hive and clipped queens I am not only a bee-keeper, but am master of the situation, and can say to my bees, "Thus far shalt thou go, and no farther."

I will not take the space to explain the sys-

tem of management necessary to the successful operation of this hive, as it has been given to the public by Mr. Heddon and others, and is familiar to all careful readers of GLEANINGS. Of course, friend McIntyre or any one else would make a failure in trying to use this system with a frame 7 inches deep and 10 frames to the hive at that. The frame I use is $4\frac{1}{4} \times 17$ inches inside; and any brood-case can be used as a wide-frame super by simply providing the frames. With this depth of frame and proper bee-spaces between the cases $\frac{1}{4}$ inch, and top and bottom bars $\frac{1}{8}$ inch, I have no trouble about the queens passing from one section to the other; and my bees will remove the honey from the lower case as soon as they are interchanged, every time.

Friend Root, you say that Dr. Miller, after experimenting with the shallow extracting-chambers, arrived at the same conclusions as friends McIntyre and Holley. I notice by your catalog the top-bars of your shallow frames are $1\frac{1}{2}$ inches wide. Perhaps this had something to do with the doctor's failure with them.

I am not in any way interested in booming any hive or system, but have only tried to give to the readers of GLEANINGS the result of my experience along the line of hives; and if it will help some brother bee-keeper to increase his yields of surplus, and by so doing be the better able to provide for those dependent upon him for support, I shall be amply rewarded, and shall be only too happy to give something in return for the many helpful instructions I have received through the pages of GLEANINGS. It is useless to add that the honor of bringing this system to public notice belongs to James Heddon; and whether his patent is valid or not, I believe his rights will be respected by all honest bee-keepers.

Wakeman, O., July 20.

[The columns of GLEANINGS are open to fair and impartial testimony of this kind. The top-bars that Dr. Miller used were, I think, $1\frac{1}{8}$ in. wide. Possibly this may account for the fact that queens did not breed properly in the two sections of the hive at the same time. What he had was extracting-supers and not brood-chambers.]

Since this came to hand we have received the following from O. R. Coe, quite an extensive bee-keeper in the Catskill Mountains.—Ed.]

□ I have over 700 half-story hives, and do not propose to make or use any other style of hive than the divisible brood-chamber, but have not time now to tell why I like it better than any other hive.

Honey is a total failure up to this time. Bees are in a starving condition except as I feed them where there was not honey left over from wintering.

O. R. COE.

Windham, N. Y.

[Here is an article equally fair and unprejudiced, on the "other side."]

THE DOUBLE BROOD-CHAMBER A FAILURE.

COSTS MUCH MORE THAN THE SINGLE BROOD-NEST; WINTERS NO BETTER; THE REVERSING AND SHAKE-OUT FUNCTIONS.

By B. Taylor.

Dr. Miller, in *Stray Straws*, says:

B. Taylor, after inventing and using for many years the sectional brood-chamber, takes away one's breath by saying in *Review* that he prefers the single brood-chamber.

Now, doctor, if you should fail to recover your breath I shall not consider myself responsible for support of the widow, for you had no real excuse for losing your breath; for, while I have written approvingly of the divisible shallow brood-chamber as being very handy for doing many things that I practice in raising comb honey, such as contracting the brood-nest to hive prime swarms in, yet I have in none of my writings disparaged the larger full-brood chambers. At length I came to the time, as I have told in the June *Review*, when I had to choose between them; and I had to decide in favor of the larger full brood-chambers, upon the ground of utility alone, and for the following reasons. 1. The double brood-chambers cost more to make. I have always sold a single brood-chamber, such as I use, for \$1.25, and could not sell two sections of the shallow hive for any thing like that sum, for each section costs nearly as much to make as the larger full hive. It is true, there is a little less material in each section of the shallow hives; but in the two sections there is at least 40 per cent more material, and very nearly double the work. There are 20 instead of 10 frames; two hive-bodies instead of one, each costing in work and material nearly as much as a single full hive. Now, if I could have secured more honey, or with less work with the double brood-chambers, the increased cost of them could have been borne without loss; but after thirty years' trial I was *compelled* to know I could not. I at length became aware that I had over-estimated the double brood-chambers. Especially did this become manifest in the last few years of poor honey crops, when the struggle for bread and butter became greater. I have no apology to make for over-estimating the double brood-chambers. It was my baby, and I wanted it to be the handsomest and best baby in the whole world; but all parents know that our babies at length grow up to mature age, and their faults manifest themselves. We still love them; but if we are *wise* we see their weak points, and can not *love* their faults.

My double-brood-chamber baby grew up with more faults than my less showy, full-brood-chamber baby. I once believed the double brood-chamber wintered bees better than the full hive; but in the last few poor seasons for honey I have lost heavily in bees each spring, and the colonies in the double

hives fared as badly as those in other hives. I now *know* that it is the bees themselves that make wintering (when proper rules are observed) safe. I have long observed that some seasons bees wintered well in all styles of hives, and with seemingly careless management. I now believe I know the cause. Now, do not understand me as denying that the double brood-chamber has some good points; but its bad features overcome them. I have tested the "shake-out" function, the reversible function, about which much has been claimed; and I *know* that, for practical work, they are *arrant humbugs*.

In any hive we sometimes need to handle single frames, for various reasons, which I need not mention, as every bee-keeper understands them; and for many years, when this work had to be done in the double hives, I began the work with uncomfortable feelings. With the wire-end-frame handy hive all this work is begun with a kind of joyful feeling, for you can get into every part of the brood-chamber so easily, without any poking or prying, and with no tools but our unaided hands, that the work becomes a pastime indeed.

Readers of my writings will have noticed that I practice the same system with these hives that I do with the double brood-chamber. I still hive prime swarms on six to eight hundred inches of comb space. I contract by using two to four dummies made exactly the size and shape of the brood-combs; and in my hive I can do this work of contracting and enlarging twice as easily as with any other hive in existence. In the fall we use these hives double, but not as double brood-chambers. A queen-excluding honey-board is used between, for we have found that more bees can be raised on 1000 inches of comb, and have them ready for field work when clover blooms, than in a larger hive.

I have now fully answered the question of why I finally decided in favor of a single brood-chamber, and have done it in no hostile spirit toward any man or his interests, but have written every line with a sincere desire to benefit poor bee-keepers who are struggling to meet life's demands.

Forestville, Minn., July 16.

[I do not know that I have any comment to make, other than that I have not yet succeeded in making the shake-out feature work, nor have I seen any one do it with success.—Ed.]

Our Crimson-Clover Symposium.

HOW TO RAISE IT AND HARVEST IT.

By Arthur T. Goldsborough.

As you ask for points on crimson clover, I write to say that I was one of the first men in the country to grow it. For three or four years people have driven by to see "Mr. Goldsbo-

rough's clover-fields," as the *Star* puts it. I do not believe it does to allow one's soil to lie all winter uncovered; so, consequently, stubbles of all kinds are planted to this clover—some to cut and cure, some for turning down, and some for seed. I always save my own seed in the haulm, having no thrasher or huller. If the cutting is done after the heads show no red, it quickly dries and is put into small cocks. A canvas is then spread, and in a very short time the seed (haulms) are flayed out. Unlike other grains, the slightest touch makes the haulms loosen. These are put into bags, and sown down the wind any time you wish. I sow it from Aug. 1 to Oct. 1, and rarely cover it, as it comes up easily after a rain. After digging early potatoes I rake off the vines with a harrow, and then sow clover seed, and do not cover. When sowing turnip seed I mix them with crimson-clover seed. For several years I sowed kale and clover together; but this is not wise, because in the spring the clover hides the kale too much.

I am now sowing clover among my tomato-plants, egg-plants, corn, beans, and melon-patch, and expect the first rain to start the seed. I am very much pleased with my last year's experiment with crimson clover, in connection with red clover and timothy. About the first of September I sowed crimson clover, red clover, and timothy at the same time, on some sugar-corn stubble. After taking off a splendid crop of crimson-clover hay, I forgot that other seeds had been sown with it, and was surprised to see a showy second growth putting forth about a fortnight later. The red clover has given me a good second crop, and will be allowed to remain over. Its habit of growth is much more beautiful than red clover, as it is taller, and stands up straighter, and the heads stand together more like wheat and timothy. It is so pleasing to the eye that I have a "woodman, spare that tree" feeling, and dislike to turn it down before blooming. Indeed, I am quite satisfied with its stubble, its roots, and its shade—that mysterious agent which furnishes the rich microbes of the soil to overcome the poor ones. A little strip of my field corn had a small piece of clover-stubble turned down about May 20, and any one could tell where the clover strip began and ended, almost on a dark night. If you do not sow it before last "plowing" of corn (good farmers don't murder their corn with a plow if they own a cultivator), get on a horse, ride down the rows, and sow it at any time before Sept. 1st. It won't need any covering unless we have a drouth. Besides, the expense of the seed won't break you in case of failure.

I rarely sow more than 5 pounds per acre. Another good way is to sow it on corn stubble, and spread fresh manure over it. If the horses have been fed on clover or timothy you will catch a good stand of these next spring.

I have not tried it with buckwheat, because the latter seems always to exhaust my lands. As a bee crop, nothing equals it. I have fifty colonies of bees, and they roar on it all the time. It is useless to sow in the spring. Two years ago I picked out some white heads, and now have this Italian clover in two colors.

In this day of low prices and close competition no farmer or horticulturist can afford to go without it. How many ignorant men in our land will purchase, this fall, worthless fertilizers to the extent of from about five to ten dollars an acre, when fifty cents' worth of clover seed would insure results five or ten times as great! In the rural districts of Maryland most of the mortgages are held by guano merchants; and if the agricultural papers did not receive their "ads" they would tell the farmers the truth about fertilizers, just as our experiment stations are doing. Try crimson clover, and see how much manure and fertilizer you need.

Wesley Heights, Washington, D. C.

CRIMSON CLOVER ALIVE WITH BEES.

STOCK PREFER IT TO THE RED.

By W. W. Kulp.

I had a little correspondence with Dr. Miller, and I mentioned that we raised six acres of crimson clover. He wished I would write about it to some bee-journal.

My father owns a dairy-farm four miles south of where we live. On it was wheat-stubble in which the grass failed to catch. It was plowed during July, and harrowed; then in September, the first half, it was harrowed and rolled until it was in first-class condition—fine, and packed down. Remember that small seeds, especially if sown during warm weather, require fine earth, and it must be packed down, so moisture can continually come up from below. The crimson-clover seed was then sown with a seeder, and covered with a Breed weed-er. It came up nicely; and where it was very thick on the ground it grew much the best; but there was a good stand all over the field. It is river-bottom land, and in the adjoining field was a large colony, or many colonies, of grasshoppers. They moved on the clover, and ate off about 20 or more feet all along one side.

It was as green as spring grass all winter; but during cold spells in March it froze down, but sprang up quickly in April; and by May 25 it was a sea of crimson, beautiful to look upon.

Now for the bee part of it. I have an apiary of 40 colonies, now 55. About this time white clover began to bloom, and the bees began to store honey nicely. When fully out in bloom, and a few days more, my father went to cut about four acres of it. He found the whole field alive with bees—so many that one horse refused at first to go along it in the machine.

Now, no bees of any account are kept near it. After it was cut I found the flow stopped at my apiary, four miles away, and did not resume until after the middle of June, when red clover came out. White was very plentiful, but no honey. Now, I am not sure that the bees obtained the flow from the crimson clover, but there is no flow here between fruit and clover—no raspberries or wild flowers. We are not far north of Philadelphia, and the land is all farmed.

I took a bunch of dry hay of the crimson clover, and put it in the horse-rack when he was eating fresh-cut undried red clover and timothy. He left that and ate the dry crimson.

I raise Belgian hares, and I fed it to them green, and expect to feed to them one and a half tons dry before next May. They eat it every bit, and grow like weeds; but they eat ragweeds with a relish too.

I have sown one and a half acres of buckwheat and crimson clover with it; but we had only a few sprinkles of rain for a month, and the clover has not started. I intend to make it a regular rotation—buckwheat and clover right along, and expect to make the field rich. You see I read Terry. The Lord bless him and all the big and little Roots, including J. T. C.

Pottstown, Pa.

CRIMSON CLOVER IN DELAWARE.

HOW IT IMPROVES THE SOIL; NO PLANT EQUALS IT AS A HONEY-PLANT; HONEY EXCELLENT.

By T. F. Cooke.

Crimson clover is probably more extensively and successfully grown in this locality (Delaware) than in any other in the U. S. at present. We consider it a most valuable plant, for on it greatly depends the production of fertility with which to grow the luscious fruits and fine vegetables for which this peninsula is noted. Its growing has been widely extended here during the past few years, and almost every farmer and fruit-grower has tried it, and knows its uses and value. Years before it was popular, the plant was known, tried, and pronounced a failure, probably because it did not show the marked characteristics of red clover, then almost the only member of the clover family in use here. Since then, slowly at first, and with a rush later, it was adopted, and its wonderful adaptability to our style of farming has become apparent. We were told that, beneath the working soil, the ground was full of plant-food; but a trial of deep plowing to bring it up invariably resulted in disaster. This plant, with its mass of roots in the surface soil, sends deep into the earth a number of roots after water and food, and from the air it draws nitrogen. More or less of these added elements of fertility are left in the soil, whether the crop is removed or plowed under; and the results seen in the

growth of succeeding crops are wonderful. That more fertility is gained by allowing the crop to fully mature, and be removed, than to plow under while green, is believed here generally, except, perhaps, where the land is intended for late potatoes, or is lacking in vegetable matter. On such land, plowing under the green crop when in full bloom is recommended, provided always that the quick improvement of the soil is of more value than the crop which might be removed and used for soiling, ensilage, cured hay, or seed production. The straw and chaff, after removal of seed, equals in value many of our cultivated grasses in feeding value.

The value of crimson clover begins as soon as the plants appear above ground, for then they begin to act as a shade and mulch, and to use and conserve fertility which would otherwise have been leached or blown away. They soon begin to draw nitrogen, for the nodules on the roots are found in great plenty, even in early December, or before. From that on until the busy bee extracts its store of sweets from the blossoms, the roots are lengthening out and searching for food three, four, and more feet under ground. We have been told that crimson clover has no tap-roots, and therefore can not reach down after phosphoric acid and potash; also that its life is too short to accomplish the work which red clover does. The facts are, that it does do it; and it has been proved by chemical analysis. We consider the root arrangement of crimson clover more advantageous, because the mass of roots are in the surface soil, where they are most needed. It can be used with or after almost every crop. None should be used on strawberries; for these, use it the year before the patch is set. It should be sown every year in blackberries and raspberries. It will stand the winter here if sown after sweet potatoes are dug. No plant we have here equals crimson clover as a honey-plant. It produces every year, and all the time while in bloom, some three or four weeks, according to the nature of the soil and climatic conditions. The growth of the blossom seems well adapted for honey-production, as it grows in length, and the bees work on the new growth until the blossom is full grown, two or three inches in length, in many instances. The principal trouble here in getting the honey seems to be in having the bees good and strong, and ready. It comes early; and if the bees are ready the sections fill very rapidly, and the honey is excellent.

This season white clover did not produce any honey here; and during crimson-clover bloom the weather was very unfavorable for bees to work; so our honey crop is a short one.

I can furnish you no photo of the plant; but it is a beautiful sight to see our broad level fields of it, when in full bloom. It is quite a curiosity to those who travel through here, and

are not acquainted with it. A few seeds sown in a box or pot, and cared for at almost any season, makes a pretty ornament.

Dover, Delaware, Aug. 5.

ALFALFA AND CRIMSON CLOVER.

A SUCCESS IN NORTHERN ILLINOIS; CRIMSON CLOVER STANDS WINTER FREEZINGS AS WELL AS OTHER CLOVERS EXCEPT SWEET AND ALSIKE; AS GOOD A HONEY-PLANT AS ALSIKE.

By M. M. Baldrige.

I mail you to-day a small bunch of alfalfa, grown in this neighborhood, and taken from the crop to-day. If you will measure the plants I think you will find them to be from two feet to nearly three feet in length. These plants are from the second crop grown this season. The first crop was cut for hay about five weeks ago; since which time we have had and are still having a pretty severe drouth. The plants are now, as you will see, in full bloom, and some of the blossoms have gone to seed. I find more or less bees at work on the bloom, but by no means as many as upon the same-sized plat of sweet clover. This sample of alfalfa is taken from a plat planted at least ten years ago. The plat to-day is many times larger than when first planted. The plants each year have been permitted to mature one crop of seed, and to remain upon the ground where grown. This is not the proper way to do; still, the size of the plat has thereby been extended in every direction.

From what I have seen here for at least ten years, I am satisfied that alfalfa is as hardy and permanent in Northern Illinois as any known plant that grows here. On proper soil, alfalfa will do as well here as a farm crop as it will in Colorado, Arizona, Utah, or the Pacific States; the only difference being, that I can see, that we can not get as many crops in a season; still, we can secure three crops of hay or one crop of hay and one of seed. Any soil here that has a loose subsoil, as gravel, sand, or loam, will do for alfalfa, and there are thousands of acres of just such land in almost every county in Northern Illinois.

CRIMSON CLOVER.

I sowed a small plat to crimson clover Aug. 20, 1894. The ground was broken up and the seed raked in. The seed came up quickly, and the plants were about eight inches tall when winter set in. During the entire winter the plants remained green in color. The spring was exceedingly bad for the clover family; but the crimson stood the alternate freezings and thawings fully as well as any other clover except alsike and sweet. Some of the crimson plants died; still there were plenty left for a good stand. The plants grew to about one foot in height, and when in bloom the blossoms were very handsome, and much admired by all

who saw them. The plants were in bloom nearly a month; but I regret to state that I neglected to keep the date when the plants began and when they ceased to bloom. I permitted the blossoms to mature seed, which they did about the middle of June. It was my purpose to gather the seed, and with it seed down a larger plat; but a heavy storm of rain came on near the middle of July, and shattered the seed off. I then concluded to break up this plat and let the seed make another stand. On examination I found the seed had already germinated, and that it was unnecessary to disturb the soil. To-day the plants are about one inch high; but unless we get rain soon they may not survive much longer.

While this clover was in bloom the bees were very busy upon it. From what I have seen, I believe crimson clover is about as good a plant for honey as alsike, and that it will pay honey-producers to encourage their neighbors, who are farmers, to try a few acres of it. If they should succeed in growing a crop of hay or seed, in 1896, they will then need no further encouragement. It is my experience that farmers, as a class, are exceedingly slow in regard to trying new plants, and hence they need more or less encouragement; and yet this should surprise no one, for it is a well-known fact that not one farmer in 25, possibly 50, subscribes for or reads an agricultural periodical.

St. Charles, Ills., Aug. 5.

[Well done, friends. I hardly expected to get such favorable reports from localities so widely scattered. I am very glad indeed to hear friend Goldsborough come right out square about this matter of purchasing fertilizers indiscriminately, especially when so many of our experiment stations keep insisting that it does not pay; and I am exceedingly glad to find its value emphasized as a clover-plant. Friend Kulp's experiment of having the clover cut right in bloom, and a corresponding cessation of the honey-flow, would seem to be very conclusive. Surely it will not be a difficult matter to plant an apiary now, or very soon, within a range of a hundred acres of crimson clover. We all know what success it has met with in Delaware and vicinity. But our good friend Baldrige tells us that, away out in Illinois, it promises to succeed at least tolerably if it does not generally. And I am glad to hear such a report from alfalfa. Only yesterday a man called and asked me to go over to Chatham, ten miles away. He said there is a little patch of alfalfa over there that has given three good cuttings already this season. It is now Aug. 13. The seed was bought at our store. The soil around Chatham is heavy clay.

In regard to sowing crimson clover during the latter part of August, I am afraid it will not be a very safe experiment in our locality, judging from last season. We should remember, however, that last winter—perhaps I should say, rather, last March and April—was the most severe on any kind of vegetation wintered over outdoors, of any season for years past; and may be that, with an average winter, crimson clover, with proper attention, will get through all right, even when sown in August and September. We need a lot of facts from experience, right along in this line. Who can furnish them?—A. I. R.]

MARKETING HONEY.

Question.—Having some comb honey off the hives, and still more to take off, I wish to know how best to market it as to style, and where.

Answer.—This is a question that always arises in a bee-keeper's mind upon producing more honey than is needed to supply the wants of the family. This is also an important question; for a person may succeed in producing a good article of honey, and so put it up and force it upon the market that it will not bring the producer as much as a third or fourth class article would an apiarist who has an eye to this important item, "marketing honey." A good price for honey depends much upon the state in which it reaches market. Many will take their honey to market in bulk, piling the sections into a spring wagon in a haphazard way, and driving to the nearest town or city, offering it for sale. The grocer looks at it and soliloquizes: "This honey is in poor shape for me to sell; and if I put it in attractive shape it will cost me a cent a pound at least; also, this honey shows that the producer does not know the value of his production or he would have put it up in marketable shape; therefore, if I buy, it will be at a less figure than I would otherwise pay." So he offers three or four cents a pound less than he would expect to pay for the same quality of honey nicely crated and offered for sale by a person knowing what such honey was worth in the different markets.

In passing through the city of Syracuse, N. Y., a city of about 90,000 inhabitants at that time, I stepped into several places where I saw honey, and upon inquiry found that honey which was brought in without crating was bought for from 9 to 11 cents per pound, and sold at 15 to 17, while they paid from 13 to 15 cents for honey nicely crated of the same quality. Thus it will be seen that it pays largely to nicely crate our product: and if I had but 25 pounds of honey for sale I would crate it by all means, not only because it would pay *me*, but also because it would help other bee-keepers, and establish a more uniform price for honey throughout the country.

Well, after crating our honey and getting it in the most attractive shape possible, what shall we do with it? Much depends upon the amount of honey we have and upon our surroundings. If not more than from 100 to 500 pounds are raised, as a rule it can be disposed of in the nearest small towns to the best advantage. However, before we sell our product we should know what it is worth to us if we send it to some of the large cities. To ascertain this we should take some paper which

gives correct market reports, and I know of none which are ahead of GLEANINGS in this respect. Having such correct report: figure the expense of freight and commission out, and we have what it is worth at our nearest railroad station. If every one having honey to sell would adopt this plan, as well as crate it nicely, and then hold on to their product till they could get what it is really worth, we should soon find our smaller towns paying a uniform price, and we be taking a long stride toward making honey as staple an article of merchandise as it can ever become.

Now allow me to present a few thoughts regarding selling outright, concentrating our consignments, and also about scattering our product among a number of commission men. After arriving at the real value of my crop, as nearly as I can by the line of figuring spoken of above, I have always placed the selling price (at my nearest railroad station) at one cent per pound less than I thought it would bring when sold on commission. My reasons for so doing have been that, in case of selling outright, I have the money at my disposal, and can often invest it so as to make more than the penny a pound would amount to before a return was made from the commission man, because selling on commission sometimes proves to be a slow process of disposing of our product. In selling, I always demand cash at the railroad, when sent to a person I do not know; and if I spoke my mind freely I should say do so *always*, as right wrongs no man. I much prefer to wait a few months on the commission men to waiting a few years, or never getting any pay, of a dishonest buyer.

Some years ago I sold my crop to a dealer in one of our large cities, and was foolish enough to let it go with the promise to pay upon its arrival; but "arrival" proved to mean five years. Thus I learned a lesson I have tried to profit by.

But shall we concentrate or cooperate in marketing our product, sending all honey going to one city to one commission house, as was recommended some years ago by some? My experience says no. Some years ago I shipped my whole crop, of about 9000 pounds, to such a selected commission dealer in New York. A little of the consignment was sold in October and November at full market quotations, and enough more during the winter, at a less figure, to make one-third of the shipment, while the remaining two-thirds was closed out in May at a price far below the cost of production. Had I and the hundreds of others who shipped honey that season to this party scattered it among twenty different parties and in different cities, nearly, if not all of it, would have been sold at the prices obtained in October and November. Thus a great gain would have been made to the producer, as it costs no more to ship to ten commission men than it does to one, unless we

except the extra accounts we have to keep. Since the above experience I have adopted the plan of shipping to as many different parties as the numbers 300 to 500 was contained in my production, according to the size of my crop. Some seem to think purchasers will get "scared" over seeing honey at every commission merchant's window, so hold off about buying, but I find this is fallacious. As well talk of a butter panic being caused in the same way; for all our commission men who handle country produce handle butter, yet the price of butter keeps steady, and people buy every day in spite of butter at every store. Since I adopted the plan of scattering my crop among several commission men in several cities, the prices obtained have been very satisfactory; returns in most cases have been made quickly, and several lots sold from one to two cents per pound above the market quotations.

To sum all up, I would say, put honey up in the most attractive shape possible, and sell for cash if you can obtain as much into a cent a pound as you think it will bring you when shipped on commission. If you can not thus sell it, ship on commission to reliable parties, sending 500 pounds and under to each party.

SCORCHED WAX; CAN IT BE USED AGAIN?

I have a cake of scorched wax, about 9 lbs., which I made about seven years ago. Is there any way I could take the scorched scent out of it so as to make up in brood foundation? The A B C, 1887 edition, doesn't seem to have any thing to say about the subject.

Rock Rift, N. Y. JOHN S. CALLBREATH.

[Scorched wax, like scorched sugar or molasses, is practically ruined. You could mix the stuff in with a lot more of good wax, but it is doubtful whether it would be better than so much sand. The only thing I can suggest would be to put it into a solar wax-extractor. That which has not been entirely spoiled will separate, I think, under the action of the sun, and run down as fairly good wax. As all our wax is heated by hot water, itself heated by steam, we don't have scorched wax.—ED.]

IS IT A FACT THAT BEES SHOW A PREFERENCE FOR NEW OR OLD COMBS?

Dr. C. C. Miller:—I can answer two of your questions in Stray Straws in GLEANINGS, June 15. 1. A queen will lay in old combs every time before she will in new, as I have tried it often. Put old and new combs side by side, and the old ones will be filled with eggs first. 2. Do ducks eat bees? Yes, they have done it. One of my neighbors had ducks and bees. The bees watered at his trough, and the ducks caught many, for I saw them in the act.

Now, Dr. M., I will ask you a question: How long can you keep eggs out of the hive and have them hatch in another? One time I took a comb from a black colony containing eggs, and kept them out a little over four days, and then I gave the comb to a colony of Cyprians, and they reared black bees. C. K. DECKER.

Hanford, Cal., July 1.

Dr. Miller:—My observation leads me to believe that the queen prefers old combs to lay in, and that the bees likewise prefer the old combs for brood and storage. Combs turn dark by usage, as I think chiefly by fine varnish applied by the bees. All the interior and woodwork of the hive is also varnished in time.

Hopkinsville, Ky., June 26. D. F. SAVAGE.

[Dr. Miller replies:]

I hardly know how to account for the difference of opinion regarding the preference of bees for old or new combs. Some say bees prefer new combs both for brood-rearing and for storing honey, and yet it seems to me that in the many cases I have noticed there has been such a decided preference shown for the old comb that it would seem safe to consider it the universal rule. Will any one who feels sure that bees prefer new combs tell us what led him to this conclusion?

The duck question was raised in the *British Bee Journal*; and while there was testimony that in some cases ducks left bees unmolested, there was also very direct evidence that a duck would not scruple to lunch on bees.

As to the length of time eggs can be kept without spoiling, I have no very great knowledge. In the few trials that I made, I think eggs were destroyed after being kept out of the hive three days. But that doesn't prove that they might not be all right in other cases when kept out the same time or longer. It might be a step in advance if we could learn to keep worker eggs, for such eggs might then be sent by mail for the sake of getting new stock.

[Queens, I feel sure, show a preference for comb partly drawn out from the foundation; but I think I have noticed that, when it is fully drawn out, they will select the old combs. This seems to be more apparent toward the close of the season, when it is evident that cool nights will come on soon. A wasp-nest containing eggs and larvae was laid on my table two weeks ago. Some of the larvae were uncapped, and died in three days; but on uncapping the others at the end of ten days they made a respectful bow, and seemed very vigorous. To-day, Aug. 5, two days later, they are all dead. Probably bees are not so tough.—ED.]

IS IT A CASE OF UNUSUAL BALLING OF THE QUEEN?

I have been handling my bees on the clipped-queen plan for ten years past, but met with an experience to-day that surprised me. I introduced an Italian queen to a colony about five weeks ago; decapitated the old queen, because

her bees would sting as bad as hornets. To-day I took out the queen and clipped her; placed her on a leaf on the top of frames, and, as she went down, the bees got after her. I lifted out two or three frames at once, and found her balled on the bottom-board. I smoked the bees off, and she was stung to death. Is that unusual?

GEO. W. MARTIN.

Saltsburg, Pa., July 23.

[The case is not an uncommon one with cross bees, though usually there is time enough allowed to get the queen out of the ball before she is stung.—Ed.]

N. A. M., N. H.—Snow piled against the hives in winter is no detriment of itself, and affords some protection. The only trouble arises when it thaws and clogs up the entrance with ice. This trouble can largely be avoided by giving the hives a little slant forward in order to run the water from the entrance.

I. D., Mich.—The reason why bees fill in small slabs of comb between the frames is due, many times, to improper spacing, and to combs that are irregular. If combs are flat as a board, and spaced $1\frac{3}{8}$ from center to center, and if the top-bars are $1\frac{1}{8}$ inches wide, there will be but very little trouble. The building of similar pieces of comb in the sections can be avoided by the use of separators in connection with full sheets of foundation. In most cases, separators with starters are effective.

F. L. W., Ia.—We have not tried using chaff hives single-walled at the sides, and packed at the ends only; but reports from those who did try them were rather unfavorable, because the division-boards, even when 2 inches thick, do not seem to take the place of the thick double walls of the hives. Most colonies in our locality, even in chaff hives, are contracted down to leave a chaff division-board at one or both sides; and, of course, in the case of the smaller colonies, this gives additional protection; and, when large enough to fill the whole brood-nest, the division-boards are not needed.

B. F. M., Texas.—Bees, as a general rule, kill off drones immediately after the honey-flow. This is one of the economies of the hive; for the bees can not afford to support drones when swarming is over, and there is nothing before them but to save up their stores and go through winter. Useless consumers and non-producers must be killed off and got rid of. Of course, in queen-rearing you can prevent the loss of the drones by feeding the colony a little every day; and if you desire increase, divide, and feed each divided half a little feed to keep them going on in brood-rearing.

W. H. S., Va.—If your bees are clustering on the front of the hives, and refuse to work in the supers; and if, too, other colonies are gathering honey, the probabilities are they are preparing to swarm; or if the hive is improperly ventilated, and exposed to the hot sun during the middle of the day, give them plenty of super room, and, if necessary, raise the cover up a little and then drive them in with smoke. Of course, it is very essential that they have shade. If you can not give it to them any other way, use what is called a shade board—that is, two or three boards cleated at the ends so as to make a projecting top that will extend six or eight inches beyond the sides and ends of the hive. Of course, said shade-board should be elevated above the hive-cover an inch or so, to permit of a free circulation of air under it. In our catalog, page 4, is illustrated and described what we call the ventilated gable cover, combining to a great extent the ordinary cover and shade-board together.

Basswood is done for this season, and a good honey-flow. We have had goldenrod, and other fall flowers promise well in sections where the low lands are.

A. G. ACKLIN.

St. Paul, Minn., July 17.

My best colony stored 119 lbs. from fruit-bloom and scarlet clover. This season white clover is almost a complete failure. You can't go wrong in sowing it for honey. It will come as near paying expense of cultivation for its nectar as any plant with which I am acquainted.

J. COLBY SMITH.

Willow Grove, Del., Aug. 5.

We are having the largest honey-flow I have ever seen. My 50 colonies of bees keep me busy waiting on them, while they are just rolling in it. But, strange to say, my neighbors' bees are doing almost nothing. I have the leather-colored Italians, while they have hybrids and golden Italians.

EDW. SMITH.

Carpenter, Ill., July 22.

BITTER WITH THE SWEET.

Bees are doing very little; no basswood whatever. Last year at this time I had 1500 lbs. of nice honey, and now not even 50 lbs.; but we have to take the bitter with the sweet.

STEPHEN ROESE.

Maiden Rock, Wis., July 22.

I WOULD call special attention to a good article by Doolittle in this issue, on marketing honey.

I WOULD also call attention to the valuable articles on crimson clover (see page 629). A few more have come in, but they were too late for this number, but will be inserted in our next, and perhaps in subsequent issues also. Any thing that looks toward increasing our annual honey crop by way of artificial pasturage in these times, that will supply our farm stock with a valuable forage, should be hailed with delight. Crimson clover is now one of our hopes, and should be encouraged by all means possible, if the testimony of reliable witnesses so far received is of any account.

THE TORONTO CONVENTION.

REMEMBER the date of the next meeting of the N. A. B. K. A., Sept. 4, 5, and 6, at Toronto. Reduced railway fare and hotel rates have been secured, and every thing so far looks favorable to a big and rousing meeting. Don't forget to ask for certificates for the one-third return fare, when purchasing tickets, whether you expect to use them or not on your return. The point is here: In order to secure reduced rates a certain number of certificates must be presented. If you do not secure one it may bar out all the rest from the one-third fare return, who have to travel ten times as far. This has already happened once or twice before, simply because a few, having only a short distance to travel, "did not want to bother with it."

The following is the program, from Secretary Hutchinson, so far as it is yet prepared:

The Bee-keepers' Union; its Past, Present, and Future. T. G. Newman, Chicago, Ill.

Amalgamation of the North American Bee-keepers' Association and the Bee-keepers' Union. Doctor C. C. Miller, Marengo, Ill.

Address of Welcome, etc. Hon. John Dryden, Minister of Agriculture, Toronto, Can.

A short address, Jas. Mills, M. A., L.L. D., President Ontario Agricultural College, Guelph, Canada.

Introducing Queens. S. T. Pettit, Belmont, Ont.

Bee-paralysis: What we know and should do about it. E. R. Root, Medina, Ohio.

Mistakes of Bee-papers and Bee-journals. Allen Pringle, Selby, Ont.

How Bee-keepers might receive more benefit from the Experiment Station. R. L. Taylor, Lapeer, Mich.

Who shall winter bees out of doors, who in the cellar? F. A. Gemmell, Stratford, Ont.

What is indicated by color in Italian bees? J. P. H. Brown, Augusta, Georgia.

The proper size of a Brood-nest, and how it shall be decided. Jas. Heddon, Dowagiac, Mich.

The surest and best way of raising a crop of Comb Honey. B. Taylor, Forestville, Minn.

Some things of interest to Bee-keepers. G. M. Doolittle, Borodino, N. Y.

Legislation for Bee-keepers. R. McKnight, Owen Sound, Ont.

How to Feed Bees properly. H. R. Boardman, East Townsend, Ohio.

BURR-COMBS AGAIN; HONEY-BOARDS VS. THICK-TOP BROOD-FRAMES.

IN the last *Review* Mr. Hutchinson has an article entitled "Dispensing with Honey-boards." In speaking of brace and burr combs he says the remedy has been to use thick top-bars; that there is little difficulty in making the bars, but that there is difficulty in securing accurate spacing. His reason for so thinking is that bee-journals are still describing methods for that purpose. I can't see why this should prove that accurate spacing is impossible. If Bro. Hutchinson could work with us in our yard for a summer or two, with Hoffman frames, I think he would agree with me that there is no trouble in that line; neither is there any trouble from a few burr-combs. He says, "others say" that burr-combs are *lessened* only by the using of the thick bars. My own experience with such bars for five years, and almost constant observation, not only in our own yards, but in others, satisfies me perfectly that it is only in rare instances that they are built over the frames I have mentioned; and so rare have they been that almost anybody would say, who has had experience, there is no trouble worth speaking of. Mr. Hutchinson thinks it is a mistake to throw aside honey-boards, inasmuch as their cost is slight, and that they should not have been thrown aside, because "others say" there is trouble with burr-combs over thick top-bars. As to the matter of cost, he figures that at one cent a year for each board. This does not figure any thing either way, because it would be offset by the cost of the thick top-bars, and that should be thrown out of the account. The only objection he can think of with the honey-board (aside from the cost) is that it must be pried off when the brood-nest is open. And right you are, Bro. H.; but it is a very *big* objection, and especially so during the robbing season, when robbers are ready to pounce upon the hive, and chunks of honey are torn loose, and the drippings are smeared over the combs. The building of such is a waste of energy and a loss of wax and time on the part of the bees that should have been bestowed on the sections.

Mr. Hutchinson asks, again: "What does the practical honey-producer want to be opening his brood-nest for?" . . . "It is only in special cases that such treatment becomes necessary. A good bee-keeper can nearly always tell from outside appearances whether all is well inside of the hive." I will grant this is true to a certain extent, and once or twice I have written upon this phase of diagnosis; but too much a dependence upon this is too costly. At the risk of back-tracking a little I must confess that I can get a much more satisfactory idea of the brood-nest — one that may save dollars — after

seeing both surfaces of *one* brood-frame from the center of the hive. With the thick-top-bar sort of Hoffman self-spacing, it is a simple matter to get at the one frame. In the height of the honey season, when we used to use slat honey-boards, the outside indications, we will say, showed that the hive was not panning out as well as it might. In the old way I always had to rip off the super, tear away the honey with its burr and brace combs, and then crowd this way and that, one frame at a time, until I got room enough to pull out one all smeared with honey, to see whether the queen was laying regularly or laying at all. Now, when a frame is easily "getatable," as in the case of the self-spacers, the intelligent bee-keeper will judge almost unerringly the exact condition of the hive clear through the brood-nest, by seeing that one frame. For instance, if it is well filled with brood on both sides, and honey along the top-bar, it is pretty certain that every other frame, with perhaps the exception of the two outside ones, is equally well filled with brood. But if, on the other hand, the frame examined is sparingly filled, and no eggs, the indications are that there is very little brood in any of the frames, and that the queen is a poor one.

In conclusion, Mr. Hutchinson says that, in the use of non-burr-comb self-spacers, "we have destroyed that most convenient function of allowing frames a lateral movement." I just can't agree, anyhow. We get lateral movement in its perfection with self-spacers. Instead of fingering over each frame, four or five of the non-spacing sort, to get room to remove the one, we pry down in the center of the brood-nest, in the case of the self-spacers, and split it into horizontal halves, making a space of $\frac{1}{4}$ in. extra. Now it is easy to remove any one frame, because there will be no bulged combs; and the whole set of frames of either half may be handled *en masse*; two, three, or four frames may be shoved back and forth *at one operation*. That is why it seems to me that lateral movement can "be secured in its perfection, *only* by the self-spacing plan; but I grant there is no satisfactory lateral movement with the *standing* self-spacer; and what I have said implies the *hanging* kind. Now, if Bro. Hutchinson could work with us a couple of seasons—not that he lacks practical knowledge of the subject of bee-keeping—he would not depend on what "others say" on this question, but would conclude that the burr-comb nuisance, with self-spacing Hoffman frames, is *nil*, and that the very rare instances where they are built, and the very scarcity of them even then, is not worth considering at all. Say: can't you stop off from Toronto and let us show you several thousand Hoffman top-bars that have been in constant use four and five years, that do not show a trace of burr-combs, past or present? What you can see with your own eyes will be worth far more than what "others say" on this point.

A VISIT FROM THE EDITOR OF THE "AMERICAN BEE JOURNAL."

We all of us, big and little Roots, have had a most enjoyable visit from Mr. George W. York. From the very first a pleasant, and, I might say, a sort of kinship feeling, sprang up between us. I was attracted by his out-and-out spokenness, and gentle and Christianlike bearing; and the more I have come to know him, the more I esteem him—not as a rival, but as a co-worker. (Mutual-admiration society? Well, call it what you like, if I admire my friends and am not afraid to say so.)

Mr. York could stop but a very short time, so we endeavored to make the most of him while he was here. After showing him over the Home of the Honey-bees he made a remark something like this:

"Why, it seems to be ten times bigger in reality when I come to go through it than it appears on paper."

The point that pleased me was not the bigness of our establishment, but that we evidently had not tried to make the outside world think it is so much larger than it is in reality. Bro. Hutchinson, you remember, very kindly said of it, when here, that it was a good deal larger *inside* than outside.

Mr. York has had a good honey year, and one of his colonies has secured something over 100 lbs. of comb honey, a sample of which he brought. I believe it is about as fine-flavored honey as I ever tasted, alfalfa not excepted, and I thought so at the time I tasted it at his home last fall. It reminds one of a slight flavor of vanilla, and leaves a decidedly pleasant after-taste. In color it is a little darker than clover or basswood, and is somewhat of a greenish cast. He has asked me to name the source of it; but I never tasted any thing like it. Other bee-keepers, I am told, have been asked their opinion, and it seems they have been unable to tell what it is.

I suggest that the editor of the *American Bee Journal* take a ramble across the country, and follow those bees up. Let us have a name for that new honey. I might explain that his home where his bees are, is at Ravenswood, a suburb of Chicago, and his bees have access to the open country along the outskirts of the town.

Along in the afternoon we took a run through our apiary, went over the Hoffman frames, and manipulated that one Heddon hive; tried the shake-out function,* peered into queen-rearing nuclei; in fact, we were so busily engaged among those pets that we actually forgot our supper, and Mrs. Root had to send Huber over after us.

The next morning Mr. York was to take the train at Sterling, twelve miles south of Medina.

*It worked as it has always done for me—bees got all over the ground, up my pants legs; queen could not be found—in fact, it didn't work at all. I'd rather find queens in the good old way.

He wanted to go the night before and stop over at that point; but I wouldn't hear to that, for he must stay over with us. Our early trains not reaching there in time to catch his train, I drove down there with him; and such a delightful chat as we had in the early morning! We discussed bee-keepers, bee-papers, and bees in general; and you may be surprised when I tell you that we touched only incidentally upon the subject of amalgamation. Both of us were content to let the best judgment of the members of both societies settle the question.

THE DISCUSSION ABOUT THE BEST SIZE OF
HIVES; SHALL IT BE CONTINUED IN
GLEANINGS?

ALTHOUGH I have asked our readers once or twice whether the subject as above might not become wearisome, only one correspondent, so far as I know, has written a protest. All the rest have said, "Go on, Bro. Root; we are getting new light and new points." Bro. Hutchinson, in the *Review*, is frank enough to say that he is "really becoming tired of this discussion," because "so many of the correspondents are arguing at cross-purposes;" and that "it seems as though they were both right and wrong." Over against this, in the same issue, Mr. Hutchinson's right-hand man, the inimitable Hasty, says this:

The continued discussion of large and small hives in GLEANINGS seems likely to prove an eye-opener to us. We thought we had all the ways in which a journal could proceed, and we had not. The go-as-you-please way of every writer choosing his own subject, the question with symposium answers, snappy and right to the point, and the special number devoted to a special topic, all have been familiar to us this long time. In use, however, the second and third of these methods had got pretty well worn out, and yet very few questions in apiculture could be regarded as *settled*. It was left for GLEANINGS to take up a topic and stick to it, and squeeze it, and wring it, until the last drop of available juice had been wrung out. Why not, in the course of time, have each of the greater topics similarly treated? A joint agreement of the leading papers for this purpose wouldn't be amiss.

It seems to me Mr. Hasty pretty nearly hits the nail on the head. It was formerly supposed that a symposium in one number or two would just about settle a question; but as experience goes on, we have been shown many a time that our old conclusions were wrongly drawn; and it is only by *continued* discussion and digging up of the facts, or, as Mr. Hasty says, sticking to it and squeezing it, and wringing it until the last drop of available juice has been wrung out that we finally get at the truth. While I do not believe the question in GLEANINGS has been continued too long, perhaps some others feel like Bro. Hutchinson; and on the principle that a preacher who preaches too long a sermon spoils its good effect, it may be wise to draw the discussion to a close.

In the mean time, let us not forget that we have had a few "eye-openers." Let us rehearse just a few of them. (1) More bee-keepers are using cubical hives than we supposed. (2) A larger number find the ten-frame hive preferable to the eight-frame than we had any idea of; and (3) it is evident that some bee-keepers are, or have been, getting along with too small a brood-nest; and especially is this true in the South and West. (4) Some like divisible brood-chambers that can be contracted or expanded at will, and think this is the best solution of the problem. (5) Others who have tried them do not find them to be an entire success, and have finally concluded there is nothing better than full-sized brood-frames — that is, a brood-nest with a single set of combs.

But perhaps the biggest eye-opener of all is the fact that (6) the eight-frame hive is not as generally accepted as about the right size for all bee-keepers as we have thought.

Incidentally, I might say right here that the real thing in my judgment that brought the eight-frame hive into prominence a few years ago was the idea of contraction. It was then thought advisable to reduce the brood-nest anywhere from the full size of hive (ten) down to four, five, or six frames. Later on, eight frames seemed to be as small as it was advisable to go. When bee-keepers began to use a two-frame dummy or division-board in the ten-frame hive generally, they reasoned this way: "What is the use of my having two frames extra space and a dummy if I do not need them, when I buy more hives? All the brethren use the eight-frame, and I might as well fall into line;" but nowadays there is very little contraction, and many are beginning to feel that *any contraction* is a mistake, because it encourages swarming, and incessant swarming means little or no honey.

Another eye-opener, and closely related to that preceding, is (7) that bee-keepers at large have been running too much toward small sizes in hives, and now the tide is turning slightly the other way. Just where it will land, nobody knows. Now, the question arises in view of this, "Is it wise to stop right here?" I confess I do not know, and ask for greater wisdom of our many readers.

The interest in any discussion, it may be well to remark, depends largely on whether one is interested in the thing discussed, or in this case whether he is thinking of changing his hive; whether his hives are all worn out, etc. If one already has a lot of good sound hives, no matter what they are, he will usually say, "I will stick to what I have," and we will say he is right; but at the same time he has a sort of feeling that, when the general discussion shows *something different* as being better than what he is already using, it may become tiresome. But this does not apply to friend Hutchinson, I am sure.

FLORIDA TRAVELS.

At Kissimmee, when the train stopped we were welcomed by beautiful music from a brass band, played by a group of young ladies standing on the veranda of one of the fine hotels. I suppose everybody wonders at the queer name of this queer town, situated in one of the pleasantest parts of Florida. There are many stories in regard to its name. One is, that a very modest young miss inquired of a young gentleman whom she met, "Are you going to *Kissimmee*?" (meaning to inquire if he were going to the town in question). I did not learn what reply the young man gave; but when you come to hear the people speak of the town it sounds differently from what you would think to see it printed; for the accent is on the second syllable—the first light, and the last one very faint—*K'sim-m-y*. I had been intending to make some stop at the very pretty city of Orlando; but I was getting along so slowly I felt the necessity of hurrying up. Mr. E. J. Baird is a dentist. I went into his pretty office, and sat down until he had time to inquire my wants; and it was worth a small farm to see the sudden change in his countenance when he found the editor of GLEANINGS in his reception-room. He was so glad to see me that it seemed almost cruel to tell him that I must take the next train, and that I could not even visit his pretty home.

I omitted to mention, in the proper place, that, while we were passing through Winter Garden and Oakland, we had a view of beautiful Apopka Lake. But we had another view from the other side, as we passed the town of East Apopka. I pushed on to Tavares. Well, when you see Tavares in print it will trouble you to pronounce it, almost as much as Kissimmee, Thonotosassee, and other similar names. Tavares is to be pronounced this way—*Ta-var-eez*, putting the whole accent on the second syllable, giving the *A* the sound it has in the word *air*. I presume these beautiful names—these strange weird names that we find all over in Florida—were given by the Seminole Indians, and theirs is a wonderful history; but we have not space to go over it here.

I reached Tavares after dark, and it was raining. I was a stranger in a strange land, and I had purposed walking over to Mt. Dora before bedtime. I was told that it was at the other (the east) end of the lake giving the town its name; but of course the late hour and the rain and the darkness forbade. I was a little homesick, and longed for the companionship of friends, such as I had been meeting all through Florida. I put up at the hotel; but the colored waiters, with their starched and spotless linen, and high prices for every thing, to match, did not make my homesickness any better. I hope our colored brethren will not think I have any prejudice against them—quite the contrary; but I am prejudiced against any man or woman, colored or white, who looks down upon humble, every-day working people like myself, from the lofty heights of their starched and polished style. If I have not told it right, you probably know what I mean, any way. I told the lofty clerk I would pay for supper and lodging, as I wished to walk over to Mount Dora and take breakfast there. At this he drew himself up still more loftily, smiled in a supercilious way, and said I could never reach there on foot, for it was *eight* miles. I presume

he looked down with disdain and pity on the man who would get up at daylight and walk that distance for the sake of—well, we will say for the sake of being somewhere *else*. It seemed to me the price he charged was quite ample for a whole day's board and lodging. Was I doing the right thing to travel that distance on the Sabbath, to be among friends? Wait a little. I did not see a single human being on that whole trip, because I made it before anybody else was up. After walking a couple of miles along the shores of the pretty lake I began to experience the same sort of second wind in walking, that I do in riding a bicycle; and I burst forth in songs of praise and thanksgiving to the great Maker of heaven and earth. I told him my wants and needs. I could talk out loud, for the most of the way I was right in the wilderness, with the lake on one side, and, of course, there was none to hear but the birds that cheered me with their morning songs. I prayed out loud for the friends I had left, and for the dear wife and children at home, and for the boys who were bearing their burdens while I was taking things so easy. I asked the dear Father the question whether it was wrong for me to get up thus early and enjoy his holy Sabbath. If answers come to us in peace and joy, and an ease of conscience, then the answer came to me that I was in the straight and narrow path. My example was not bad, because I chose that early hour when nobody could have been offended or misled by my example.

I reached a hotel, and had a half-hour's rest before breakfast was ready. The distance was only *six* miles, and not eight, come to get there. The breakfast was much more to my liking; and the ways and manners of the people were in such strong contrast with those at Tavares that I expressed my satisfaction and thanks before all the guests. This seemed to break the ice; and after bantering me a little I felt fully acquainted with the people—enough so to express a wish that I might meet them all at the church during the forenoon; and I was rejoiced to see the faces of some of them there later on. This nice breakfast that suited me so well, both in quality and the way it was served, was 25 cts. My supper only, mind you, the night before, was 75 cts., and lodging 75 cts. besides.

Our good friend C. H. Longstreet resides at Mount Dora. He and his wife and all his house are good old-fashioned Methodists. I talked with the people at the Sunday-school at the pretty little Methodist church, and to the Endeavor society in the evening, at the Congregational church. Near Mount Dora I passed the beautiful Chautauqua grounds of Florida. Friend Longstreet is a gardener as well as a bee-keeper, and he showed me some of his work in sub-irrigation in Florida. He dug out the ground in one corner of his garden to the depth of a foot or a foot and a half, and then lined this excavation with water-lime cement spread right out on the ground. The cement was built up around the sides of the basin, so it would hold six inches of water. Then the hole was filled with rich soil. A tile was put down in to carry the water to the bottom of the cement basin; and when the plants need water it is poured in till the ground is saturated. The experiment was a complete success; and it gave the little orange and lemon trees a start away beyond those not thus irrigated.

The matter of having numbered tin labels for hives has recently been mentioned in GLEANINGS. Friend Longstreet makes a very neat tin label of can-bottoms. One edge is turned up so as to keep the tin flat, and secure from being bent or bruised, and there is plenty of room to print a large plain figure so you can read it as far off as you can see the apiary. Perhaps I

might remark that tin cans, and, of course, can-bottoms, are a little more plentiful in Florida than in any other part of the world. And this lets out the secret that, notwithstanding the great abundance of fruits and vegetables in Florida during certain seasons, there is nevertheless a tremendous traffic and consumption of almost all sorts of canned stuff brought from the North. Florida does not seem to have caught hold of the canning business very much as yet. The Seminole Canning Establishment at Fort Myers is, if I am correct, the only institution of the kind I came across.

On Monday, Mr. Longstreet's son very kindly took me, with his horse and buggy, over to Sorrento, where I met Nellie Adams, whom I have mentioned before as having regained her health and hearing since her sojourn in the land of flowers. Her brother has one of the finest orange-orchards in the whole of Florida, perhaps. He has a large rotary pump operated by a steam-engine on the banks of one of the most beautiful lakes I ever saw. He had just got the plant in working order, and I felt sorry I could not make him a visit at the proper time, and see him operate.

All through Florida I was told that no good brick could be made in that State. In fact, they shipped their brick by rail and boat all the way from Georgia; but in the neighborhood of Sorrento I was agreeably surprised to find brick-kilns making nice-looking brick of Florida clay, to ship by rail anywhere wanted. I stopped to ask a number of questions of the men who worked in the brickyard, and who were taking down the bricks in the kiln. Finally some one asked where I was from. I mentioned Ohio; and at a venture I said my name was A. I. Root. One of them started in surprise, and asked if it were really possible that I was the "A B C" A. I. Root. I asked him what he knew about the A B C book. He said he had read it all through, and so had another of the men. (Friends again where I least expected to find them.) My good friend Nellie declared I must let up on my flying trip long enough to visit a greenhouse conducted by a couple of sisters—special friends of hers. I suppose I looked a good many interrogation-points, for she replied:

"Yes, Mr. Root, there is a *greenhouse* down here in Florida; and as it is something unique I want you to see it. And these two women also manage it almost entirely alone."

In view of this, of course I was ready for the trip. Down among the beautiful flowers and the beautiful plants—at least, such as had survived the terrible freezes—I found two nice-looking girls hard at work among the plants they loved. The Brooks sisters have done business enough, I believe, to issue a small catalog. I can not tell you of the many interesting plants, flowers, and fruits that I found there. Their greenhouse is not covered with glass, but with cotton sheeting rolled on rollers. But they had not seen our tomato-book, and their arrangements are rather imperfect, so it seemed to me. During the last freeze they had a terrible time in protecting their stuff, even in a covered house; and one reason was because the force of the wind played such havoc with their curtains, as I knew it would as soon as I saw it. If I am correct, they have one building, something like 200 feet long by 50 wide, with cotton sheeting to cover it entirely when frost threatens.

At Orange City Junction, where I was obliged to wait for the train, I came across a lot of Congregational ministers. They were on their way to a conference at New Smyrna. While we were waiting for the train several of us visited the famous Blue Springs, only a mile or two from the junction. This blue spring takes its name from the beautiful transparent waters, with a

little tinge of indigo—enough to make the waters look like the vault of heaven on a summer's day; and on the pebbly bottom of the blue waters issuing forth from the great spring we saw the same beautiful colors, rivaling those of the rainbow, and incrustated with pebbles, shells, logs, and limbs of trees, and wonderful submarine mosses and other vegetation, until the bottom looked like an enchanted land. Great fish a yard long or more swam leisurely past us, or remained motionless until the gentle strokes of the oar startled them from their noonday reverie. A dear brother—at least I learned to consider him so—handled the oars so as to leave the surface as smooth as possible, that A. I. Root might gaze unhindered, and take in the shining beauties of the crystal depths. There may be other good people in the world; but, oh how safe I do feel in the presence of such men! I am never nervous for fear they may tell loose some startling oath, or that they may tell some impure story. What a wonderful privilege it is to be one among a company of men who are devoted, heart and soul, toward seeking first the kingdom of God, and his righteousness! We finally reached the end of the creek or river, and I gazed down into the crater where the azure waters boiled up. The country is so wild, rough, and broken in the vicinity, that almost the only access to the real head of the spring is by boat.

While riding on the train on my way back to New Smyrna, somebody touched me on the shoulder and said:

"Excuse me, sir; but did I not hear you say you are from Ohio?"

I assented. Then he asked me my name; and when I gave it I witnessed another sudden change in a stranger's countenance as he rose up and sat by my side, and told me his name was Donaldson, and that years ago he used to preach in Medina Co. He was another of the band of pastors on their way to the conference. During the afternoon, however, I slipped away from my pastoral friends; and before meeting them again I went through that little experience I have mentioned to you before at Lake Helen. While we exchanged mutual good-bys and God-bless-yous at New Smyrna, I gave them a brief account of my afternoon's experience. Said one of them (if I remember correctly it was Rev. W. S. Blaisdell, pastor of the Congregational church at Tavares, the very church I ran away from before anybody was up) something as follows:

"Brother Root, if these people all follow that little text you gave them ('thou hast loved righteousness, and hated iniquity'), all the powers of evil that the world contains can not lead them astray. Nay, farther: even the prince of darkness himself will be powerless to do you harm, no matter where you go, or what class of people you mingle in with. Only let that be the whole sentiment of your heart, the desire of your soul, to 'love righteousness and hate iniquity.'"

THE FLORIDA TRAVELS; BY A CALIFORNIAN.

Mr. A. I. Root:—I have just read "Florida Travels," and must say that it is wonderful how you take in every thing in your travels, at a glance, as correctly as you do. You have told nothing but the truth.

In February, 1884, we shipped 10 quarts of strawberries, in with another man's berries, and sold them through C. S. Durling, of Duane St., New York, for \$3.00 per quart. Our strawberry-vines began bearing in January, and continued until June. Ours were the Newnan Seedling. There are but few varieties that bear at all there. Our berries were on thin land; that did

the best. We had one acre that was very rich, but we got large vines and hardly any berries from it.

There is an orange-tree three miles south of Gainesville, on Alachua Lake, or Paine's Prairie, as it is called, that, in 1882, bore 18,600 oranges. A New England man bought them on the tree at 2 cents each. Now figure it up and see if it is not \$372.00. This tree is at Old Fort Harley; is 75 feet high, and 50 or 60 feet spread of limbs, and has had no cultivation or manure for years.

If you will look over GLEANINGS some years back you will find a communication from a man who had been in Florida a few months, condemning the Newnan strawberry. He said it was the poorest of poor berries. Evidently, he is not an A. I. Root kind of man.

Upper Lake, Cal.

G. P. SHIRES.

EARLY POTATOES.

This season we have had an unusual opportunity for testing the comparative earliness and other qualities of the new as well as the old sorts of early potatoes, for the frost cut them all down to pretty nearly one dead level. Various kinds of potatoes had been brought into the market when one man showed me several bushels so much larger, nicer, cleaner, and handsomer than any thing else, that I uttered an exclamation of surprise. Finally I said:

"Why, my good friend, what kind of potatoes are these? and how did you manage to get them of such size since the frost?"

"Oh! they were just coming out of the ground at the time of the frost: and as there was only an eighth of an acre I covered them with straw. Besides, they are Burpee's Extra Early. I have had them two seasons, and I pronounce them the best early potato in the market."

"Well, these are really Burpee's Extra Early, are they? And you live on clay soil, as I do, so you did not have really the best kind of potato ground. How many did you get from that eighth of an acre?"

"Why, there were just about 25 bushels, large and small. Of course, I brought you the best ones."

After some little urging he said he thought he ought to have about 65 cts. a bushel for the lot. I paid him 70 cts., and felt happy besides, and I guess he did too. Now, friends, here is a yield of 200 bushels of potatoes per acre, of about the handsomest potatoes you ever saw in your life; in fact, they brought 5 cts. a bushel more than he asked, on account of their size and beauty. Is not that money enough to make a man well satisfied? Early as it is, I am going to save these potatoes for seed. I am not afraid to undertake it, because I did the same thing last year. And, by the way, I have a potato-story to tell you.

On the 28th of June, after turning under some Parker Earle strawberries where we had had quite a heavy picking, we planted some Early Ohio and Lee's Favorite potatoes. They had been kept in the cellar, and had not been cared for as they should have been, especially during the month of June. Some of the sprouts were six inches long. But I directed the boys to turn the boxes upside down, pour the pota-

atoes out as carefully as they could, then separate them, letting the roots and sprouts remain on the potatoes as much as possible. Each potato was carefully put into the ground, the sprouts held up and planted as we would plant cabbage-plants. Some one who saw me taking so much pains said the sprouts were no good, and that I had better pull them all off. I knew better, however, for I have for many years tried the same thing. A pretty fair rain fell almost immediately afterward. The white, sickly-looking sprouts gradually turned dark green, and they began to grow. I knew what to expect; but this time the experiment went away beyond my expectations. Let me explain that the strawberries were mulched with coarse stable manure. This manure had produced quite a growth of weeds. Another coating of good manure was put on top of the weeds; and when we plowed, a man had to help put the stuff all under. We have a good plow, however, and the boys made a good job of both the plowing and the marking. The marker, however, which is Darnell's furrower, came so near tearing up the trash underneath that we covered them by hand. Well, before July was out these potatoes were knee-high, almost covering the ground, and some of them in blossom, and about the handsomest stand of potatoes you ever saw. Not a bug has ever touched them, and there are very few punctures from the flea-beetle. Of course, there is no symptom of blight. When I told people that that big stand of potatoes had been in the ground less than 30 days I almost feared they would think I was becoming reckless in my yarns about high-pressure gardening. The little patch is really an astonishment to everybody. With so much manure they may be scabby; but from similar experiments made in late planting I hardly think they are.

Now, when you have some potatoes left, and they get great long sprouts on, and become in consequence so soft that almost anybody would pronounce them unfit for eating or any thing else, just remember this experiment and see what you can do along in the same line. It takes some work to put them out properly. I know; but it is only just a little more labor in planting; and less labor, in fact, through all after-cultivation, for the potatoes are ahead of the weeds; and more than that, ahead of the bugs, and usually ahead of the blight.

SUB-IRRIGATION VS. TOMATO ROT.

Some time last fall Ernest decided that he wanted a water-closet in his bath-room. As the house stands a little higher than a part of the ground we use for market-gardening, I told him I would dispose of the sewage and water for him, without expense. Ordinary sewer-pipe, cemented at the joints, was used to carry the sewage down as far as the dividing-line between his ground and mine. Then it was turned into six-inch tiles. Each tile was one foot long, and they were buried from 20 inches to 2 feet below the surface of the ground, with the joints left a little loose. They ran down a pretty good incline under the pie-plant roots and other plants, for 30 or 40 feet, crossing diagonally three or four of my underdraining-tiles. Then we closed the opening, and covered the whole with earth. He felt uneasy about it, thinking the tiles might fill up, and back up so as to hinder the proper passing-away of the sewage. I told him the draining-tiles would carry away all the liquid portion, and that the roots of the plants would go down through the tiles, and dispose of all the rest. The apparatus has worked perfectly ever since, right through winter and summer. For some time, however, I did not observe the effect on plants

placed over the sewage-pipe, as I expected to. I began to think it was pretty low down. A week or two ago, however, along in July, I began to notice that the rows of tomatoes standing over the lower end of this sewage-pipe were of a bright thrifty green, and greatly overtopping the rest. The line of the sewage-pipe is now plainly discernible by the extra growth of pie-plant, tomato-plants, and every thing else over this tiling. Three or four days ago our good friend O. J. Terrell, of North Amherst, O., paid me a visit. After looking over the garden, and talking about the drouth, etc., he began examining my rows of tomatoes, trained after the experiment-station plan, on lath supported by a stout wire stretched between heavy posts. He gravely informed me that I should get hardly a good tomato from my whole plantation of several hundred large fine plants unless I gave them tremendous doses of water. And then he showed me a rotten spot on the blossom end of almost every tomato as it commenced to ripen.

"Mr. Root, that is the effect of a lack of moisture; and plenty of water is an effectual cure."

You may remember this has been suggested several times. I think the Ohio Experiment Station gave as their opinion that dry weather produces this kind of rot around the blossom end. But I rather maintained that the tomatoes had water enough. If we gave them any more on our rich grounds, they would all run to vines, etc. Finally a thought struck me:

"Oh! look here, friend Terrell. There is one thing I forgot to show you, and it is right pat to our discussion just at this minute."

Then I told him the story of Ernest's arrangement for his water-closet. Then we walked over to the spot where those great luxuriant hills stood. Lo and behold, they had grown so rank and heavy with their load of green tomatoes that they were pulling down the trellis. Two boys were called, and with stout stakes they pulled it up straight. Meanwhile friend Terrell was looking those lusty hills over, with the keen scrutiny of a scientist. He got down on his hands and knees; he crawled between the bushes; he peeked in here and there. Finally he stood up with a triumphant look on his face, and said:

"Bro. Root, you have seen the rotten-spotted tomatoes all over your plantation, where I pointed them out to you. You have even seen a bunch of pear tomatoes with a black rotten spot at the blossom end of each one on the cluster, and I told you your crop would be ruined if you did not pour on water, and lots of it. Now look here. I will give you a *dollar apiece*—mind you, a dollar—for every tomato with a rotten spot on it that you can find on these bushes that stand over or very near these five-inch tiles flooded with water, and something a little richer mixed in, say several times a day."

There, friends, you have got the fact. Ernest and I figured up that perhaps 12 or 15 gallons of water a day are flushed into those tiles. But it does not cost a cent. It is a perfect automatic arrangement. It is not only automatic in giving a tremendous crop of the handsomest tomatoes you ever saw in your life, but it is also automatic in disposing of all the sewage from the household. The whole thing stands right close by the street, and anybody can come and look at it who thinks I have exaggerated it. Because of the rot in tomatoes that has made such havoc, my loss for several seasons past has been because of a lack of water; and the remedy—at least one remedy—is sub-irrigation. And I have told you very plainly just exactly how to manage it. Somebody may suggest

that these small tiles will in time fill up, and will have to be taken up and cleaned out. Well, even if they do we can afford to do it; and very likely it will be as well or better to run the tiles a greater distance from the house, say a hundred feet or more. I do not know whether the roots of those rank-growing tomato-plants were down inside of those big tiles or not; but I rather suspect they are. In fact, that is where I planned to have them. The tiles are so large I think it will be a good while before they will be so filled up with roots and trash that the water can no longer get through them. Can any one suggest a cheaper way in the long run to manage a water-closet? And just contrast the beauty and simplicity of such an apparatus with that of an out-building with a pit or vault under it, full of the most disagreeable mixture that can well be thought of. Such things are a disgrace to the present age—at least, after one has the means to do better. And even if you have not the means, I would adopt the plan they have in Florida—the same one recommended by T. B. Terry—of having galvanized iron pails to be emptied on the garden whenever necessary. Do not, under any circumstances, have a pit or vault in the ground to endanger your wells and cisterns.

FORCING VEGETABLES UNDER GLASS.

The Cornell University Experiment Station (Ithaca, N. Y.), has just given us some exceedingly valuable bulletins on this subject. I speak of bulletins Nos. 95 and 96. If they are not furnished free on application, Prof. Bailey will surely tell you on what terms they can be had. No. 95 tells all about raising melons under glass. No. 96 discusses Grand Rapids and other kinds of lettuce: cress, egg-plant, and peas. There is also a chapter in regard to bees in greenhouses; another on the controlling of pests by fumigation. But the most valuable part is the arrangement of beds, glass, etc., for high-pressure gardening. I have never yet succeeded in growing nice celery in the winter in a greenhouse nor even in a cold-frame. As it is so easily wintered over until February any way, it is not worth while to grow it under glass, to be ready for use before March. During March, April, and May, people can always be found who will pay large prices for a nice article; and this bulletin tells how to make a success of it. The work is done by Profs. Bailey and Lode-man.

SWEET CLOVER—IS IT A NOXIOUS WEED?

In what is called the "Legal Department" of a recent issue of the *Ohio Farmer* I see in two separate places sweet clover mentioned among the class of "noxious weeds" that are under the ban of the laws of the State of Ohio. Now, I do not know how this came about, but there surely is a great blunder somewhere. First, you can not call any plant a noxious weed that is greedily devoured by horses and cattle when they can get at it. If sweet clover ever grows in pasture-lots, especially where the pasture is short, I have never yet met with such a case. It is true that stock, a good many times, need to be educated a little to like it; but our horses will now eat the dry brush after thrashing out the seed. Second, sweet clover has been for years past quoted regularly in the market, among other clovers. It is at present quoted by Nungesser & Co., 65 Pearl St., New York, at \$14.00 to \$16.00 per 100 lbs.; and there is a good steady demand for it at that price. Do the seeds of noxious weeds have a regular merchantable value? Perhaps I should be a little modest in speaking of the *third* reason why it should not be called a noxious weed. It is one of the recognized sources of some of the

finest honey that is produced in the world. In Utah it grows on the arid plain, and furnishes this beautiful honey by the carload, besides being next to alfalfa as a forage plant; and it also performs the important office of taking the alkali out of the "saleratus soil," as they call it there, so that the ground eventually becomes fitted for regular farm crops. Fourth, sweet clover sends its roots down about as deep as any clover known, into the very hardest soil, and brings up its fertility, and it is never heaved out by the frost. So far as I am informed, the frost has never yet been able to budge a root of it after it had made one season's growth. It dies, root and branch, as soon as it bears a crop of seed. I never heard of its being hard to eradicate.

OUR CRAIG AND OTHER POTATOES UP TO DATE.

The early potatoes mentioned on page 641 are now, Aug. 14, a perfect swamp of vines, and the ground is bursting open with potatoes already the size of hens' eggs. How is that for only about six weeks from the time of planting? Our Craig potatoes are also making a perfect swamp of dark-green foliage—no symptom of blight, and no trouble from the severe drouth, and not a bug on them anywhere. Prof. E. C. Green, of the Ohio Experiment Station, who has just been looking them over, says that, if nothing hinders, there will certainly be 300 or 400 bushels per acre. Of course, an early frost might cut short the yield somewhat. Mr. Green said he doubted whether there was a better field of two acres in the whole State of Ohio. I certainly have seen nothing like it in my travels. The whole two acres is now well mulched with coarse stable manure. This mulching holds the moisture from the rains we have been having, so they are not likely to suffer much, whether it rains or not; and I am rejoiced to know that the Craig Seedling is holding up bravely the reputation I gave it from the record of those ten hills last year. Those who have the Craigs had better take good care of them, and not be in a hurry to sell. Some sort of price will be fixed on them later.

CLOVER-MIDGE, OR SOMETHING ELSE; WHAT THEY LOOK LIKE, ETC.

In GLEANINGS for June 15 I noticed an editorial on the clover-midge and its work on the red clover, in which you said you had not as yet noticed that the midge had attacked the white or alsike clover, and said you would like to hear from your readers.

One year ago last spring I sowed an eleven-acre field to alsike clover. About four acres along the north side of the field was gravelly ground on which the clover died out during the drouth of last summer. The rest of the field had a nice stand of clover this spring; but, being short of corn ground, I concluded to plow up all but about three acres in one corner of the field, and put it in corn. I noticed, when I was plowing, that the clover-leaves were all full of holes, but I did not know at the time what caused it. I marked out the field both ways with a sled marker, and planted it with a hand-planter. I commenced to plant early in the morning, and I was surprised to find the marker-marks almost green with worms on that part of the field where there had been clover. There were no worms where there had been no clover. I counted 35 worms in one mark, within a space of 7 feet. They evidently had come to the top of the ground to feed on the clover, as they disappeared again in the ground when the sun got hot during the day.

A few days after I had planted the corn I pulled some pigeon-weed out of the clover on

that part of the field which I had not plowed, and I found the same kind of worms at work on the under side of the clover-leaves, although the leaves looked, as you said, as though they had been riddled with shot. I do not think that it has hurt it any for seed, as the heads seem to be fairly well filled. The worms were green in color, and all the way from $\frac{1}{4}$ to $\frac{3}{4}$ inch in length. Were they what you term the clover-midge? C. C. WELSH.

Fostoria, Ohio, June 25.

[Friend W., the green worms you speak of are not what is known as clover-midge. Will our Ohio experiment station please straighten us out?—A. I. R.]

HOW TO PROPAGATE AND GROW BASSWOODS, ETC.

Can you tell me how to propagate and grow the basswood and Russian mulberry?

Gracy, Ky., July 31.

J. G. NANCE.

Basswood-seeds must be gathered when fully mature, and planted in good soil. Give them a mulch of some kind, say forest-tree-leaves. I suppose a mulch of any sort of grass would do as well. They need to be planted as soon as gathered, and left outdoors to freeze and thaw. The plants will come up in the spring about the time that weeds start. After this they can be handled about like any other nursery stock. As their natural home is the forest, however, in more or less shade, a shading of slatted shutters, or one made of lath or cotton cloth, seems to be a benefit. They can grow quite close together until they are a foot high, when they should be transplanted in rows wide enough apart to cultivate, and about six inches apart in the row. The distance apart depends, of course, on how long you let them stand. If you are going to plant a basswood-orchard, I would put the trees only 15 feet apart each way, cutting out half of them when they get large enough to make valuable timber. This thing should be kept in mind with all sorts of forest-trees: During our hot dry summers, shading and mulching are always of benefit; and, in fact, I have seen basswoods do better right in a thicket of briars than when standing out in a clean cultivated field. The briars and brambles must, of course, take the moisture and fertility from the ground; but they furnish dense shade and mulch. A mulching of forest-leaves is probably better than anything else you can give. I am not familiar with the cultivation of the mulberry: but I think likely the above would apply to the mulberry also, except that it is more of a cultivated tree than the basswood.

NIGHT-SOIL; HOW TO USE IT.

Friend Root:—Please inform me how I can best use the contents of privy vaults instead of artificial fertilizer on celery grown after the Nivens method, and only a short distance from the house. I water with hose from tank a few feet above. It should probably be deodorized, and mixed, to make of even consistency. I have some 4000 plants on some 65 square rods.

Utica, Ill., July 1.

ALFRED MOTTAZ.

Friend M., your ideas are about right; but I do not believe your compost will be suitable for celery by the Nivens or any other method until it has had time to "ripen," as gardeners term it. This stuff is too rank for most vegetables unless composted with stable manure, muck, weeds, or something of the sort, and allowed to stand, say, six months or a year. Then it will produce very good results. But the value of it, I am inclined to think, has been somewhat

exaggerated. I would rather have a ton of good old stable manure than a like quantity of the best night-soil.

Additional Editorial.

MR. HUTCHINSON, in the *Review*, pertinently asks the question, in reference to the subject of number-tags for hives, "Why is it necessary to have numbers at all?" Our colonies at the Home of the Honey-bees have never been numbered, because we did not consider it necessary. But a large number of practical bee-keepers, Dr. Miller among them, consider it almost indispensable. This is especially true when record-books are kept.

THE amalgamation of the N. A. B. K. A. with the B. K. U. is still somewhat an open question. A great majority, I fear, do not care very much one way or the other; but those who have expressed themselves at all, seem to be nearly all in its favor. So far as I can see, there is every argument in its favor, and little or nothing against it; and were it not for the General Manager of the Union, under whose leadership that organization has done so well, I should feel that the combining of the two societies was a virtually accomplished fact. I rather suspect the subject will be warmly discussed at the next meeting at Toronto.

SOME one has said that Dr. Miller ought to label his jokes; at all events, a writer in one of the Australian papers takes one a little seriously. Here is what he says:

Dr. Miller's Straws seemingly at times get very much astray. Here is a sample from GLEANINGS: "The *Australian Bee Bulletin* says, at the last of January, 'Swarming may now be said to be practically over.'—I should think so! That accounts for the big crops they get there. We could get big crops too if we would work the poor bees right through the winter."—The good doctor has evidently lost sight of the fact that, while January is the middle of winter in the northern hemisphere, it is the middle of summer here in Australia.

If the writer of the above could have seen the comical twinkle on the doctor's face, he would not have found it necessary to explain to him what was perfectly evident to the doctor. Now the joke is on [loud laughter] our Australian friend.

THE GOOD AND BAD FIVE-BANDERS.

ONE good brother bee-keeper, a queen-breeder, writes that I am doing an injustice to a certain class of breeders when I say that the five-banders are not all bad, and that this stock from some breeders is all right; that, moreover, when I do not specifically name the breeders who furnish the nice five-banders, the good breeders are classed with the bad. Well, I grant there is something in this; but if I

specify the former, those not mentioned would "howl," and claim that they were not used right. Furthermore, I do not know all of the breeders who are conscientiously rearing five-banders that are strictly from Italian stock, and are all that is claimed for them; and I do not feel it my duty to keep still when I know that at least part of the five-banders that are reared, and perhaps a large percentage, are as cross as hybrids, and lacking in good wintering qualities. I do know that very little fault is found with leather-colored stock reared by any breeder. This stock does not win favor because of beauty, but because of real merit; and real merit is bound to win and bound to please in the end.

No more figwort seed wanted.

HONEY-PACKAGES.

We have a good supply of honey-packages, listed in our catalog, ready for prompt shipment to those in need. If there is something in the line of honey-packages which you prefer, and we do not list, call our attention to it and we may be able to supply you. We have something new to offer which we will illustrate in our next issue.

BUSHEL BOXES.

We are having a booming trade in bushel boxes, the orders averaging 300 to 500 a day. We are getting them off with reasonable promptness, considering the disadvantages under which we work with our wood-working building shut down for repairs. We expect to be running again full blast within a week or two at the outside, and can take care of all orders entrusted to us. We have a rip and a cut-off saw in our packing-room, to fall back on till our other machinery is in shape to run.

CALIFORNIA SAGE HONEY.

Our car of extracted white-sage honey has just arrived as we go to press, and proves to be extra fine and white so far as we have examined it. This is the kind of honey which does not granulate, and for that reason it is very desirable to put up in glass packages for retail, because it remains liquid almost indefinitely. We offer it in cases of 2 cans, 120 lbs. to the case, at 8 cts. per lb. A single can at 8½ cts.; large lots at special prices quoted on application. Samples free to prospective customers; to others, 5 cts. each to pay for package and postage.

THAT NEW EDITION OF THE A B C OF BEE CULTURE.

We are pleased to announce the long-looked-for and much-sought-after new edition, the 62d thousand, is finally completed. We have been a long while in getting it from the press, it is true; but besides the usual large revisions, we have added 48 extra pages of entirely new matter to an already large book, so that it now contains 472 pages, double column, like these, and still the price will not be increased. Besides the numerous changes and additions to the body of the work, to bring the matter clear up to the present state of the industry, we have greatly enlarged the biographical department, and new faces of prominent bee-keepers, who have made a success, are shown with appropriate sketches. The picture-gallery also comes in greatly expanded, with short description of each picture. These pictures are large half-tones illustrating apiaries, exhibits, and other phases of bee-keeping.

Although the work is supposed to cover every subject on which beginners desire information, we have collected together in one department of 32

pages, "Answers to Questions from Beginners." These are practical, every-day questions, representative in their character, that we have picked up for the last three or four years in our correspondence, and have subsequently been answered in the pages of GLEANINGS. It might almost seem superfluous to have them in a text-book at all, since many of the questions are answered in the body of the book. But experience has shown that certain specific cases arise in special localities requiring specific answers, and as these questions are repeatedly asked we feel that the answers will prove here, in permanent form, valuable to many others. To facilitate reference, questions of a kind are grouped together; for instance, questions concerning comb and extracted honey are by themselves, and in like manner those touching feeding and bee-pasturage, etc., and so on clear through.

The whole work, from fly-leaf to fly-leaf, has been all gone over and thoroughly revised, so we believe it is fully up to the times, is comprehensive, and as specific as it is possible to make any text-book. No expense has been spared in its preparation in the way of engravings; and certainly no beginner who is able to keep even one hive of bees can, for the small sum of \$1.25, afford to be without it. As formerly, this book can be had of all dealers in bee-supplies.

WHAT SHALL WE PLANT DURING THE LAST OF AUGUST?

Kidney wax beans will make green beans for table use and pickles, if the frost holds off, ordinarily. And speaking of string beans reminds me that our "Best of All" green-podded string bean is now ripening its crop of seeds. Our people around here pronounce it the most tender and luscious string or snap bean they ever came across; and if you do not use them all green they are a splendid shell bean for the table. This bean is certainly an acquisition. My attention was first called to it in Florida, and our crop is principally for the Florida trade. As it matures quickly, I think you can get green beans yet this fall from seed sown at once. Price, per pint, 10 cts.; quart, 15 cts.; peck, \$1.00; bushel, \$3.50; 5 bushels, \$15.00; 10 bushels, \$25.00. If wanted by mail, add the customary 15 cts. per quart for postage.

Eclipse beets will be just right for table use late in the fall. They will stand a considerable frost without injury.

If you can get cauliflower-plants, now is the best time in the year to set them out, in my opinion. We always get nice ones during the cool frosty weather of October and November—in fact, the nicest we get at any season of the year.

Celery will do if you have great big plants, and ground that is tremendously rich with stable manure.

Corey's Extra Early corn will surely make fodder, and may make roasting-ears.

During this month and next is the time to plant out winter onions and sets, white multipliers, and American Pearl. See prices on page 573 of our issue for July 15.

Alaska and American Wonder peas will often produce a good crop when planted the last of August.

All kinds of radishes flourish now as well as or better than at any other season. But the Chinese Rose Winter is considered the best for fall planting.

Now is just the time to get in spinach; but, like celery, it wants the very richest ground that you can fix up, to come to real perfection. Remember, this plant, with a little protection, can be left out of doors all winter; but it is a great deal finer if you have some glass or even cotton cloth to put over it during extreme weather.

Purple-top Globe turnips sown now will give you the very best table turnips, although they are likely to be injured by the frost before they get to be of very much size.

Asparagus and horseradish roots can be planted in August and September; but as a rule you had better wait until the last of next month, or even in to October.

This is the great month for planting strawberries; and, thanks to our recent abundant rains, we are ready to supply almost any quantity unless it should be the Parker Earle and Edgar Queen. These are so late with their crop of fruit they have not yet made very many runners.

In regard to honey-plants, buckwheat put in now may escape the frost; better put in some crimson

clover with it, however, and then you will have two chances for a crop for the bees instead of one.

Alsike and White Dutch, peavine and mammoth clovers, sometimes make a stand sufficient to go through the winter; but it is risky business.

I do not know much about alfalfa; but I think that, in our locality, it is better to sow it during June. Rape can be sown for bees during this month or next, as it blossoms sometimes in four or five weeks after sowing. Borage will also make blossoms; but as it seems to have but little use except for honey, very little of it is sown nowadays. Seven-top turnip can also be sown any time this month or next; but this plant has also dropped out of use, as it is of but little value except for honey. A small patch of it for early greens in early spring, however, is a pretty good thing, and it is a splendid plant to turn under for enriching the ground.

AMERICAN PEARL ONION-SETS.

We are just now harvesting the finest crop of these we ever raised. As we put in a pretty heavy seeding, there are a good many small ones mixed in—some not larger than peas. These small ones are less likely to send up seed-stalks; and as they are sold by measure you get a greater number of onions for your money where the sets are small. Price, quart, 25 cts.; peck, \$1.50; bushel, \$5.00. The price of the large-sized sets, say an inch in diameter, or more, will be just half the above prices. These are just as good in every way, except that you will have to take more pains to break off the seed-stalks as fast as they appear next spring; and you will not get so many sets in a bushel if you use the large-sized sets. Now, and during the month of September, is the time to plant them. We have had the best success in wintering where they start and grow, and get well rooted in the fall. These onions have been described so often that I suppose almost every one is more or less acquainted with them by this time.

Winter rye, the well-known strain that we have been furnishing for so many years past, \$1.00 per bushel; 2 bushels, \$1.80, bags included.

KIND WORDS FROM OUR CUSTOMERS.

I am pleased with the hives, and we think the lawn-mower is perfection. GEO. W. RUSSELL.
Ocoonita, Va., June 10.

I should like A. I. Root to see he is not fighting a battle against the swindlers single-handed. I am thankful that on this side of the globe we have men who are not afraid to speak the truth. I desire to thank him for the way in which he has shown up the electric gentlemen. M. EVANS.
North Ipswich, Queensland, June 5.

CRANE SMOKER A DANDY.

I received my order, 39,859, day before yesterday, and find every thing exactly right. This is the best hive I ever saw, and the thick top will stand our hot suns. The Crane smoker is a dandy. I am greatly pleased with these things, and extend you my sincere thanks. W. P. MOORE.
Portland, Tenn., July 15.

A KIND WORD FROM ARKANSAS.

Bees and honey crop are good; fruit of all kinds never better; corn and cotton and potatoes, oats and hay, in fine condition. Come down this fall and I will give you a bear-hunt. ANTHONY OPP.
Helena, Ark., June 29.

[Well, well! I have had invitations that were hard to resist, a good many times, but I do not know that I was ever before asked to go on a bear-hunt—and come to think of it, from an old friend whose name has been on our subscription-list so long that it looks like one of the old landmarks; and that is what makes it specially hard to resist. Friend Opp, how fast can a bear run when it is right down mad? Could I take my wheel along? Is bear meat good to eat? Suppose you should take me off on a bear-hunt, and I should get hugged to death—what would become of Mrs. Root and the rest of them away back here in Medina? Now, then, you look out or you may get taken up. Thanks for the invitation, any way.—A. I. R.]

Promptness is What Counts.

Advantages of Bee-Escapes.

No sweat steals down the heated cheeks and aching back of the bee-keeper as the result of standing in the hot sun puffing, blowing, smoking, and brushing bees; no time is wasted in these disagreeable operations; and no stings received in resentment of such treatment: the honey is secured free from black or even the taint of smoke; the cappings are not injured by the gnawings of bees; and robbers stand no show whatever. If there are any broken burr-combs they are cleaned up by the bees inside the hive, before the honey is removed. **Leading Bee-keepers use the Porter Escape**, and say that without a trial it is impossible to realize the amount of vexatious, annoying, disagreeable work that it saves. The cost is only 20 cts. each, or \$2.25 per doz. As in the past, this escape is manufactured by the Porters, but The A. I. Root Co. has secured control of the sale for this country. Order of your dealer or of

Ridgeville, : Indiana.

HONEY COLUMN.

CITY MARKETS.

CHICAGO.—Honey.—We find a steady demand that takes all arrivals of comb that is first quality at 15c. The off grades bring 9 to 13, according to color, quality, and condition. Extracted, white, 6½@7; amber and dark, 5@6. Beeswax sells on arrival at 25@27, according to color and cleanliness.

R. A. BURNETT & Co.,

Aug. 20. 163 So. Water St., Chicago, Ill.

KANSAS CITY.—Honey.—The receipt of new comb and extracted is fair, and the demand not large, but will increase with cooler weather. We quote new 1-lb. comb, No. 1 white, 14@15; No. 2, 12@13; No. 1 amber, 11@12; No. 2, 10@11; extracted, white, 6½@7; 6½; amber, 5½@6; southern, 4½@5. Beeswax, 22@25.

C. C. CLEMONS & Co.,

Aug. 20. Kansas City, Mo.

KANSAS CITY.—Honey.—We are receiving new comb and extracted. New white comb, 14; extracted, white, 6½@7; dark, 4½@5. Demand good. Beeswax, 22.

HAMBLIN & BEARSS,

Aug. 24. Kansas City, Mo.

BUFFALO.—Honey.—The demand for new honey is slightly increasing, but as yet very little is coming forward. We would advise early shipments of light stock, which no doubt would result well here, and would possibly bring 14@15 for fancy; other grades, 10@12; buckwheat moving very slowly.

BATTERTON & Co.,

Aug. 20. Buffalo, N. Y.

ALBANY.—Honey.—New comb honey meets with a ready sale. Have had a number of small consignments, and disposed of them soon after arrival. There is also quite a demand for extracted in glass jars put up in attractive style. We quote white comb honey, 12@15; mixed, 11@12.

CHAS. McCULLOCH & Co.,

Aug. 20. Albany, N. Y.

BOSTON.—Honey.—On account of the warm weather there is but little call for honey, with a fair supply of new stock. We quote comb, 16c. Florida extracted, 5@6; California extracted, 5@6½, with a light demand.

E. E. BLAKE & Co.,

Aug. 19. Boston, Mass.

CHICAGO.—Honey.—We quote fancy white 1-lb. section comb honey in nice clean packages at 16c; other grades of white honey, 14@15; amber, 13@14. We are having a good trade in extracted honey, selling light amber and white at from 6@7; dark, 5@5½, depending on quality and style of package. Early shipments to market advised so as to permit of sale before cold weather sets in. Beeswax, 28.

S. T. FISH & Co.,

Aug. 22. 189 South Water St., Chicago, Ill.

CLEVELAND.—Honey.—Our honey market is picking up. No. 1 white comb in 1-lb. sections is selling at 16c. White extracted, 6@8. Beeswax, 25. There is call for new honey, and we look for better prices than last season.

WILLIAMS BROS.,

Aug. 7. 80 & 82 Broadway, Cleveland, O.

PHILADELPHIA.—Honey.—Honey is arriving more freely, but the demand has not sprung up; yet we are making some few sales both of extracted and comb. We quote new extracted, 4½@6. Fair to fancy comb, 9½@16. Beeswax has not recovered from the blow it received in the spring on discovering so much adulterated. Buyers are suspicious, and buy sparingly. We quote 22@25.

WM. A. SELSER,

Aug. 20. No. 10 Vine St., Philadelphia, Pa.

MILWAUKEE.—Honey.—The condition of this market is favorable for shippers. The stock of old crop is being steadily reduced, and the supply is now small, especially extracted, and we can now handle liberal shipments, and on section honey we can now quote choice 1-lb. sections, 15@16; good, 13@14; dark, 8@10; extracted, in pails or kegs, white, 6½@7; dark, 5@5½. Beeswax, 22@25.

A. V. BISHOP & Co.,

Aug. 24. Milwaukee, Wis.

DETROIT.—Honey.—Best white comb honey in fair demand at 13@14; no dark offered. Extracted, 6@7. Beeswax, 24@25.

M. H. HUNT,

Aug. 19.

Bell Branch, Mich.

ALFALFA HONEY. very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c.

OLIVER FOSTER, Las Animas, Col.

FOR SALE.—Two carloads of prime mountain comb honey in 24-lb. glass-front shipping-cases; labeled goods, full weight, 1-lb sections; 10 cts. per lb. on the tracks here. A. B. MELLEEN, Acton, Cal.

FOR SALE.—White comb honey, 14 and 16c. on board cars.

G. R. ROUTZAHN, Menallen, Pa.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty.

J. P. IVY,

Secretary Bee-keepers' Association,
Phoenix, Maricopa Co., Arizona.

Wants or Exchange Department.

WANTED.—To exchange several good safety bicycles. Honey wanted. Send sample.

J. A. GREEN, Ottawa, Ill.

WANTED.—To exchange 26-in. planer, power scroll saw, all iron; tenoner, and mortiser, for portable sawmill, or other wood-working machinery. Will give a bargain for cash.

Geo. RALL, Frenchville, Trempe Co., Wis.

WANTED.—To exchange foundation-mills and honey-extractors for honey or wax.

I. J. STRINGHAM, 105 Park Place, New York.

WANTED.—To buy 2 tons extracted white-clover honey, in 60 lb. tins.

GEO. G. WILLARD,

270 Pearl St., Cleveland, O.

WANTED.—To exchange latest improved Marvel magic lantern, best quality (cost \$45), also 100 choice views, for honey, beeswax, or offers.

CONVENTION NOTICES

There will be a meeting of the Southeastern Bee-keepers' Association in Fort Scott, Kan., Sept. 19th, 1895. All are cordially invited.
J. C. BALCH, Sec., Bronson, Kan.

The Southwestern Wisconsin Bee-keepers' Association will hold its next meeting at Platteville, Wis., Oct. 8th and 9th, 1895. Come all. Don't get discouraged, even if we haven't got a crop of honey. We shall have a good time at Platteville just the same. Bring your wives and daughters with you. Many interesting subjects will be discussed.

M. M. RICE, Sec., Boscobel, Wis.

A NEW PAIR FOR HONEY.

We have recently been investigating Record's tight butter-package for honey, and it seems to be most desirable.

In cut No. 1 we show the tin package with the tight cover lifted, representing the groove near the top of the package into which the lugs shown on the cover lock themselves when sprung into the package, instantly sealing it tight.

We also show the little wire lever thrown out which is used to pry the lever out of the seat

when it is desired to open the package. It will be readily understood that the package may be opened and closed as often as desired, always shutting and locking itself tight. If it is desired to be absolutely water and air tight a small rubber band is used around the groove of the cover, forming a gasket, but for ordinary purposes this band is not necessary.

These pails are made in sizes to hold 1, 2, 3, 5, 10, and 20 lbs. of butter or lard. The honey capacity is approximately 1½, 3, 4½, 7½, 15, and 30 pounds. Cans without bails, of still larger capacity, are made; but for shipping honey in retail packages the four smaller sizes would be the ones used. We will furnish these pails at following prices:

No. 1, holding 1½ lbs. honey, 6c. each; 55c. for 10; \$5.00 per 100.

No. 2, holding 3 lbs. honey, 7c. each; 65c. for 10; \$6.00 per 100.

No. 3, holding 4½ lbs. honey, 8c. each; 75c. for 10; \$7.00 per 100.

No. 5, holding 7½ lbs. honey, 10c. each; 90c. for 10; \$9.00 per 100.

No. 10, holding 15 lbs. honey, 15c. each; \$1.35 for 10; \$12.50 per 100.

SHIPPING-CASES.

The letter from S. T. Fish & Co., in another column, calls attention in a practical way to the importance of neat and attractive cases. We have a later letter from Fish & Co., inclosing one from the shipper of the lot of honey which sold on arrival at 16 cts. In this letter the shipper says the cases came from The A. I. Root Co. We have been wondering why we get more orders every year for shipping-cases. The only reason we can assign is, that, at the very reasonable price we ask, we furnish a very neat and attractive case. See our catalog, for prices. Right here I might mention the fact that the car of alfalfa honey we received last fall was put partly in our cases, but mostly in cases made at a local mill. The cases were not tight, nor the honey protected with paper as we recommend in our catalog. As a consequence, the sand and coal dust injured the looks of the honey, and the selling price as well. If you have a nice article of honey, do not sacrifice two or three cents in the selling price by not putting it up in the most attractive package, and properly graded.

HONEY MARKET.

We are having a fairly good demand for honey, but look for a better trade, this month and later, when fresh fruit is not quite so plentiful. We offer fancy comb honey in 1-lb. sections, 12 and 24 lb. cases, at 16c. In crates of about 200 lbs., 15c. We have a lot of very fine extracted clover and basswood honey, in 60-lb. cans, which we sell at 9c per lb. for a single can; 8½c by the case of 2 cans; 2 cases or over, 8c per lb. We offer California sage honey at ½c per lb. less than these prices. This is very fine white honey, which does not candy or granulate. Samples mailed for 5c to cover cost of package, or free to intending purchasers.

SECOND-QUALITY A B C BOOKS.

In finishing up the last edition of the A B C of Bee Culture, before the new edition just finished, we find still quite a number that we classed second-quality, and offer at 65 cts. postpaid to close out. They are in cloth binding, and scarcely distinguishable from the firsts. A number of those who have received one from our notice of May 15 wrote us that they could not see, in looking them over, why we should class them as seconds. We have about 60 of the books; and if they go off as rapidly as they did in answer to our first notice they will last scarcely three weeks. Who wants one?

Black and Hybrid Queens For Sale.

Hybrids for 20 cts.; mismated for 30 cts.

C. G. FENN, Washington, Litchfield Co., Conn.

18 hybrid queens, a few of them mismated, reared this summer from daughters of one of Doolittle's selected queens; all good layers; 25 cts. each; or 5 for \$1.00.
J. P. F. SMITH, Liberty, Mo.

The Convention

fill orders just as well and promptly as I can. "By return mail" will be the motto, just the same, whether I am at home or not. Single queen, \$1.00; six for \$5.00. One queen and *Review*, \$1.50; one queen and the book, "Advanced Bee Culture," \$1.25; queen, book, and *Review*, \$2.10. Remember that the queens are bright, young tested queens, and strictly first-class in every respect.

W. Z. HUTCHINSON, Flint, Michigan.

Proof Beyond Doubt.

I opened several hives. He had no veil; was in the apiary $\frac{1}{2}$ of an hour; was not bothered once. Try them. Untested guaranteed queens, 75c. Send for wholesale price list.

A customer, looking over my 400 hives in home apiary, said, "Where are your bees? Mine were flying all around thick this morning." I said, "Just stop; look down at any hive." He was amazed. They were just pouring in thick with their heavy loads. This proves two things—they can't be excelled as workers, and quiet.

No. 17.

STRAY STRAWS FROM DR. C. C. MILLER.

CANADIAN reports, as well as reports from this side the line, indicate a short crop.

KEEP UP the discussion about hives. [Yes, but I must have more votes than this to keep it up.—ED.]

KEEP OUT of GLEANINGS the silver discussion. [Quite right: and all other political questions.—ED.]

SUPERSEDING queens, when left to the bees, is usually done in May, says C. W. Post in *C. B. J.* I think my bees do most of that in the fall.

HUTCHINSON says, as a rule a honey-board need not come off oftener than once in three years. He also thinks it is needless to number hives.

AFTER USING divisible brood-chambers for years, Hutchinson says he has never seen any evidence that the queen is likely to neglect one section.

"MORE GOOD PEOPLE in the world than we sometimes suppose," is what I said, and Somnambulist warns me, "Look out, doctor, for mud-balls from the anti-mutual battery."

SQUEEZING and wringing still bring a good lot of juice out of the hive discussion. As long as that is the case, it is well to keep it up. [Yes, I rather think so; but I want our readers to indicate their pleasure.—ED.]

DEUTSCHE IMKER, a German bee-journal, contains the information that, of the 3500 varieties of plants in that region, only 60 yield both honey and pollen; 900 yield honey only; 250 only pollen, and 130 propolis.

A COLORADO MAN thinks I'd better quit trying to get honey from straws, and come out there where I can get it from alfalfa. Perhaps so; but if I can get the alfalfa to come here, that may be cheaper than to move.

MOVING BEES. Here's a plan for short distances, given by H. E. Hill in *American Bee-*

keeper: Put three frames of brood with queen and most of the bees on new location. In six days move the rest, cutting out queen-cells.

"WE'VE ALWAYS to keep in view the fact that next year's greatest problem may prove to be the caring for an unusual crop," says Somnambulist, in *Progressive*. I've kept that in view so long, Sommy, that my eyes begin to feel strained.

THE QUEEN of a colony that has wintered badly is thereby injured herself, and is better replaced, says C. W. Post, in *C. B. J.* Such a colony is usually hard to pull into shape; but I never before thought of blaming the queen. He may be right.

CARNIOLANS are said to be hard to distinguish from blacks. Some say it's easy, but I don't remember seeing in print *how* to tell them apart. [It simply can't be told on paper. There is a difference, but you must *learn* to know it by actual comparison.—ED.]

THE *American Bee-keeper* reports that S. M. Keeler gets combs built down to bottom-bar by using bottom-bars of $\frac{3}{32}$ wire. [I have no doubt of it. They will do more; they will build clear past them on to the next set of frames below. They did that with some of our three-eighths-square wood bars.—ED.]

LAYING WORKERS sometimes make just as nice and smooth work as queens, filling worker-cells regularly with one egg in a cell, with no difference that I could detect. But I think it is generally if not always in cases where no drone-cells are present, and generally a queen-cell with two or more eggs will tell the story.

THE COST of honey-boards or thick top-bars doesn't figure either way, you say on p. 636. Beg pardon, but it does. A honey-board costs several times as much as the extra thickness of top-bars. My honey-boards don't last like top-bars, and they cost me a good deal more than a cent a year. [Perhaps you are right.—ED.]

WOOD-BASE FOUNDATION, says *Canadian Bee Journal*, was used by D. A. Jones 15 years ago. All was lovely while the bees were busy

working, and rearing brood; but when out of work they got into mischief and set to work to eat away and remove the wood. [This was just our experience about that time too.—ED.]

DO BIG TREES and big honey crops go together? California has both, and the enormous yields of honey in Australia come from a land which invites California to a contest as to big trees. The Sydney *Evening News* contains accounts of trees having a circumference of 40, 50, and 60 feet, and one tree has a girth of 136 feet at 5 feet from the ground.

EXPERIMENTER TAYLOR says in *Review* that, usually, the royal jelly deposited in a cell amounts to about half a common thimbleful. Haven't the women in that region rather small hands? [The women in your locality must have big hands. (Beg pardon.) I should have said Taylor's statement was about right for here.—ED.]

MELILOTUS ALBA is considered only a weed in the Northwest; but in the South it is prized as one of our most valuable forage crops. . . . Mowed before the plant becomes too large and woody, the quality of the hay is first-class, and in nutritive quality equal to any of the clover family."—*E. Montgomery, in Agricultural Epitomist.*

QUOTH YE EDITOR, on p. 620, "There is a method, and it is practical, to control fertilization. See article by James Wood." With feverish haste I found the place, then a nervous shock, a collapse. Not a thing new in it. Not a thing that ever was or ever will be of value except to a very few isolated individuals. [I knew it was not new; but I don't agree regarding its limited application.—ED.]

"USELESS CONSUMERS" is a term commonly applied to bees reared after the honey-harvest commences. S. E. Miller, in *Progressive*, raises a protest against the term being thus used. I've been looking for that sort of protest before. [What better term can you suggest that conveys the idea so well? I don't think of any. It is true they may not *always* be "useless," but if the rearing of them could be deferred a little later it would be better.—ED.]

SOME 420 COLONIES are kept in the home apiary of C. W. Post, says *Canadian Bee Journal*. I supposed such numbers could be kept in one apiary only in the far South. Now they're going to commence doing that sort of thing in Canada, so as to make us poor mortals in the middle feel we're nobody. [But wouldn't Post's bees do far better if they were divided into two yards—one yard two or three miles away?—ED.]

I WAS SURPRISED lately to see, within a few miles of home, a field thickly covered with hay-cocks, showing a heavy yield in this year when the hay-crop is very light. Coming closer I found it was alfalfa three years old. I didn't suppose alfalfa would grow here; but there it

was, and the second crop had been taken this year. I saw no bees on it. [There is a fine field of alfalfa not a great way from us. We didn't suppose it would grow as well as it does.—ED.]

R. F. HOLTERMANN says lindens planted in the streets are rarely of benefit to bee-keepers, but must be in the woods to be of much value. I wish that might be numerously contradicted. [That is not true around Medina, nor in any other place I have been in the United States during the bloom. I have a row of trees in front of my house that are the equal of any trees in the woods for the roar of bees at the proper season of the year. Of course, bass-woods do better in the woods; but that those along the streets are rarely of benefit to bee-keepers is not true with us.—ED.]

"A REVELATION" is what Somnambulist calls the statement in GLEANINGS, that the majority of bee-keepers put their sections on the market without scraping. That may be a good name for the statement, but a good name for the thing itself is "abominable carelessness." [Many times a statement may appear to be a revelation, but that does not signify that it is untrue. Bee keepers who are in the habit of always scraping their sections are apt to think all others do. You remember the Frenchman who thought because he always "parlez-vous-ed français" therefore all the rest of the world did.—ED.]

A VISIT AT B. TAYLOR'S.

THE MAN, HIS HIVES, FIXTURES, ETC.

By Harry Lathrop.

Off-years are good for some things; and one is, that they allow a bee-keeper leisure time to visit other apiaries, and broaden his knowledge of men and methods. On the 19th of June I started for the Northwest to visit the home and apiary of B. Taylor, near Forestville, Minn. After a pleasant ride down the Wisconsin Valley, crossing the Mississippi at North McGregor, and on through Northern Iowa, I arrived at Wykoff Station, where I was met by Mr. Taylor, according to previous arrangement, and taken out to his beautiful home, 8 miles distant. Although Southern Minnesota is in the main a prairie country, the Taylor apiary is located in a wooded section, with narrow valleys between high limestone bluffs. This part of Minnesota produces about all the honey-plants common to the Northwest, including an abundance of basswood and white clover. To be concise, there were three things in which I was espe-

cially interested—the field, the man, and, the work.

The location has been partly described. It is a land of beautiful valleys traversed by cool spring brooks, the natural home of the brook trout, and abounding in cool leafy woods in which the thrifty basswoods are plentifully distributed. The Taylor apiary is beautifully situated in one of these valleys, on sloping ground at the foot of the bluff, where it catches the first beams of the morning sun, and is naturally sheltered from winds.

Now as to the man and his methods. Mr. Taylor is more than a bee-keeper. He is a fine mechanic and an inventor. He has a nice shop containing machinery (constructed by himself) for making every conceivable appliance used

B. TAYLOR.

in bee-keeping. All his work, whether it be building a house or a bee-feeder, is thorough and exact. No time is lost in his apiary through having fixtures that won't fit. I did not see an imperfect joint nor a warped cover on the place; and when Bro. Taylor makes any claim or describes any appliance in the bee-journals you may be sure it is just as he says it is. My expectations were fully met. He informed me that each appliance he uses was adopted after many experiments, until finally he has selected what he considers the best after many practical tests, and he has the things themselves to show each step by which he has arrived at present conclusions. Having time, and proper tools and machinery, this was much easier for him to do than it would be for many. Very few bee-keepers can attempt to do what he has done in the mechanical department, but must adopt, as best they can, the methods of others.

Mr. Taylor has never made an effort to establish a supply business. He seems to have little or no desire to do a large business, therefore his well-equipped shop and beautiful machinery stand idle a large part of the time.

The hive adopted is the same in nearly every respect as his shallow-depth sectional hives, except in the depth of the frame. The one he prefers is only a little shallower than the ordinary Langstroth frame. He prefers what would be considered a small hive, and gets very large swarms from them too, as I can testify from what I saw. I was fortunate in being there just in the swarming-season. In honey production he can show a record above the average; but that may be, and probably is, largely due to a good location. He is not so particular as some in regard to pure races of bees; but his colonies show the mark of health and vigor—the result, evidently, of properly bred queens.

I was much interested in the following: His house-apiary, bee-cellar, readily movable self-spacing frames, interchangeable hive-body, bee-escape, section-holders, solar wax-extractor, feeders, and swarm-catcher. The latter appears to be his pet hobby at present; but for myself I am so well pleased with my method of working with clipped queens that I am not much interested in swarm-catchers. His is intended to be placed on the hive the moment you notice the swarm beginning to come off.

One thing I saw was quite instructive. I was shown a lot of hives containing nice clean combs of white honey from which the bees had died during the past winter, although they had been properly cared for. The cause assigned was that, on account of dry weather last fall, they had gone into winter quarters with old bees instead of young ones. The result was, they died off from old age just as we all shall if we don't die sooner from some other cause.

Mr. Taylor is assisted in his work by his youngest son Jewell, whom he expects to succeed him in that work—his other son, living near by, preferring fruit culture.

Mr. Taylor is an expert in gardening and fruit-growing, and gave me a few valuable hints along that line. I was told that, some years ago, he tested one hundred varieties of native wild plums on his grounds. These were brought from different parts of the Northwest. Out of this number he has selected one that he considers very superior. How few would take the time, and have patience, to conduct such an experiment! After all, where do you find more all-around handy men than among the bee-keepers?

In closing, I will say that I was so kindly treated during my stay, and enjoyed myself so well, that I feel just as though I wanted to go again some time.

Browntown, Wis.

CRIMSON CLOVER.

"BY LONG ODDS THE BEST BEE-PLANT;"
HONEY VERY FINE; WHEN TO SOW;
GREATEST RESTORATIVE
OF THE SOIL.

By A. F. Ames.

Friend Root:—I see you want information about crimson clover. I have had but one year's experience with it as a bee-plant; but this year it was by long odds the best bee-plant here—much better than white clover ever is here in the South. It blooms very early, so one must have bees strong in time. The honey is very fine—not quite so white as white clover. It is the greatest, soil-renovator in the world, and will succeed where red will not. It should never be sown in the spring—at least in the South—but early enough in the fall to make a good growth to carry it through the winter. Here, although late sowing will winter all right, it will make a very light crop, as it must make a good growth in the fall and winter. If left to ripen it will reseed itself. The best time to cut for hay or to turn under is when part of the heads are brown. If sown so early that there is danger of blooming, pasture it. I have no fears of mine, sown the first week in July, blooming this season. It will endure as much cold as red, or perhaps more, and make over twice the growth in the same time.

Claremont, Va., Aug. 6.

CRIMSON CLOVER "OUT OF SIGHT," YIELDING LARGEST AMOUNT OF THE FINEST HONEY.

This clover was first introduced in Virginia about fifteen years ago; but it has not been largely grown in this country for more than four or five years. It can be sown in this State in August, September, or early in October, and is in bloom the latter part of April. Farmers grow it largely in this county for early green feed, and sell large quantities in Richmond at 10 cents per hamper. We generally sow ours in the

corn after cultivating the last time, seeding about 10 or 15 lbs. per acre. As a land-improver it can not be beat; and as for honey it is simply "out of sight," yielding a large amount, of the finest quality, as you will see by the sample I will mail you soon. It is not very fine

CRIMSON CLOVER.

Re-engraved from a cut in Burpee & Co.'s catalog.

for dry hay, as it is inclined to be rather dry and woody. Like all other crops it does best on good land, although I think it will do a great deal better than common red clover on poor soil.

Reports are rather encouraging this year throughout the State, my bees giving me about 35 or 40 lbs. of comb honey per colony.

Richmond, Va., Aug. 10. F. H. JEWHRST.

CRIMSON CLOVER; HOW INTRODUCED IN THIS COUNTRY; ITS GREAT BEAUTY, ETC.

Crimson clover was introduced in this country several years ago by the late Dr. Haralline. Being a great lover of flowers, he was attracted to the plant by its great beauty, which is hardly exceeded by the finest flower that adorns yard or garden. The beautiful deep green, which may be seen all through the winter, when not entirely covered with snow, grows deeper and brighter as spring advances, until early in May, when the flowers appear, and the field changes from a deep green to a brilliant crimson, making a sight to behold; and, remember, at first its value as a forage-plant was not understood, and as a soil-restorative it was unknown; and the progress of the plant at first was rather slow. Every one admired its beauty, and numerous plots were sown for ornamental purposes; but years elapsed before farmers awoke to its value as a regular rotation crop.

Crimson clover has now been successfully grown in all parts of the Union, and is no longer an experimental crop. It is good for hay, and will yield two to three tons per acre of the finest quality. It is valuable for seed, which it produces in large quantity; is good for fall and early spring pasture; it is also an excellent honey-plant, and makes a good bee-pasture; but its greatest value is in its ability to store up plant-food, and at the same time send down deep feeding-roots in the subsoil, and bring to the surface elements of fertility that would otherwise be lost.

Crimson clover is an annual, and must be sown in its proper season. This extends from the first of August until the last of October. About 10 quarts of seed are required to sow an acre. If any of the readers of GLEANINGS would like to test a sample of crimson clover I will send a small sample by mail for a couple of stamps for postage. L. STAPLES.

Grand Rapids, Mich.

[All right, friend S.; but you may be swamped with orders; so, look out.—ED.]

A FINE GROWTH OF CRIMSON CLOVER; THREE WEEKS AHEAD OF RED; WORTH TO THE SOIL MORE THAN 30 LOADS OF MANURE.

I sowed one-third acre of crimson clover on good onion ground Aug. 20, 1894, and it made a

fine growth, and kept green until February, although the cold had been to 20° below zero. In February the top died down, but began to grow nicely in March, and was three weeks ahead of red clover on the same kind of ground. May 1st I had it plowed under, when it was 20 inches high, and there was such a heavy growth they had to use a chain to turn it under. I planted the ground to muskmelons, and the ground kept moist except about two inches on top, through the long drouth of six weeks in May and June. I think it was worth more than 30 loads of manure. I also sowed my half-acre vineyard, and it bloomed in May, and the bees worked on it lively—more than on white clover; but I can't say as to amount or quality of honey. It made fine pasture for chickens. I consider it the greatest plant ever introduced, if used between other crops to improve land by retaining its fertility and adding nitrogen. JOHN C. GILLILAND.

Bloomfield, Ind., Aug. 13.

RAMBLE NO. 139.

IN SELMA.

Although we left Murphy suddenly we did not forget to bid adieu to our good friends the Schaeffles. They all, from the head to the foot of the family, made our sojourn enjoyable, and we had reason to remember them in a substantial manner for many days. A pail of that blue tarweed honey, a bag of apples, and one of Mrs. Schaeffle's excellent pies, were all tucked into our lunch department. May the shadows of the Schaeffles never grow less.

Calaveras Co. is so full of interesting natural features that Mr. Wilder and I felt that we could have spent many more days there with profit; but southward was now our watchword. Storm-clouds began to gather in the northern horizon, and we longed for the balmy skies of our southland.

The Golden Nugget apiary, as mentioned in the last ramble, is owned and operated by Mr. Aliska. Here we find 200 colonies, the greater portion of them in a shallow hive. Before visiting this apiary I had learned that the brood-chamber and the super were both filled with 4¼x4¼ sections; but upon examining a few of them I found the sections in the super in wide frames, and the brood-combs were built from these same brood-frames down into the brood-chamber; and the brood-comb was removed every time a wide frame was removed with its sections. Mr. Aliska was not there to explain matters; for in the early morning his partner and himself and Ah Hin, the Chinaman, went to work with wheelbarrow, shovels, and picks, in their gold-mines, where the greater portion of their time was spent. Mr. Aliska, during the honey season, left the gold-mine and secured gold through the medium of his hives. Comb

BLASTED ROCKS IN THE GOLD REGIONS OF CALIFORNIA.

honey was the product, and the honey flora here was much the same as at Mr. Schaeffle's.

I found other bee-keepers in this same neighborhood. About a mile from Aliska's an old decrepit man and his wife had an apiary which they managed upon the old plan; and in referring to Mr. Aliska they said that he had recently come in with his new-fangled notions; "but them ar little section fixin's I don't believe in. I can git jest as much honey as he kin, any year; besides," said the old man, "I don't think much of them ar' miners. Wy! if they thought thar'd be a leetle gold under this yer house they'd dig right under it in a minute, an' they claim they've got a right to by law. It's a fact, stranger; one of my neighbors has gone rackin crazy trying to keep the miners from diggin' up his whole farm; and while he is sent off to the 'sylum his old wife hangs on to the farm with jeopardy."

Mr. Aliska was not the kind of man to dig up his neighbor's farms and feelings in that way, but he was at work in a tunnel trying to strike a "pocket," as it is termed, and a great deal of scientific reasoning and digging is practiced in trying to find these pockets. Mr. Aliska stated to us that he once struck such a pocket, and panned from one pan of dirt \$1500 in gold nuggets; and to find another pocket he might spend twice that amount. So goes the miner's life, lived on with the hope ever before him of great and sudden wealth. In the long run a steady devotion to the production of honey would probably bring in more nuggets of gold than the pick and the shovel.

This portion of country we now pass through shows more and more the wear and tear of placer mining. Where once were fertile tracts of land there is now nothing but piles of coarse debris and acres of ill-shaped pointed rocks. The fine earth has all been washed away, and thousands of acres of such torn surface are found in Calaveras and Tuolumne Counties.

On our journey we cross the famous Stanislaus River; Sham's, and various other flats; Jimtown, and Poverty Flat, all made more or less famous by the writings of Bret Harte, whose home, as well as that of Mark Twain, was formerly in Angel's Camp.

We gradually get beyond the mining lands, and drop, as it were, from hill to hill until we get again into the great San Joaquin Valley; and after three days' drive from Mr. Schaeffle's we are alongside the S. P. R. R. at Merced. From this point we have over 300 miles to traverse ere we get under our own climbing rose-bush and pepper-tree.

Another three days we traveled through an extensive grain and grazing country, and with it were scores of square miles of unimproved and barren lands whereon the wild goose quawked, the turkey-buzzard foraged, and the traveler accelerated his pace. The desert ap-

pearance at this season of the year was enhanced by seeing now and then the bleaching bones of some weary bovine that had given up the hopeless pursuit of forage, and had died for the want of it. The honey-bee, if located here, would find as little forage as the cattle; and it occurred to me that, while so many are talking about rearing queens upon lonely islands, here in the midst of these great plains would be a fine place to mate queens with special drones. The little queen-rearing apiary could be established for a while upon some large cattle ranch. A little sugar to stimulate, and not another bee within 20 miles! who could desire a better place?

We were pleased to reach Selma, in Central California, on Saturday evening. Here we again strike a honey-producing country and a large number of bee-keepers. Mr. J. C. McCubbin, with whom I had a pen-and-paper acquaintance, lived in the edge of the town, and upon a vacant lot near his residence we picketed our horses and pitched our tent, and sojourned over Sunday. It is good for brethren to dwell together in unity, and attend church on Sunday.

I had a sort of vague idea that our friend was a bachelor; but the idea was dispelled as soon as I looked inside the dwelling. If I must in fairness say it, no bachelor could ever keep a house in such tidy order as we found that house. A bachelor always forgets to put things back in their places; and if he does, his fingers are so clumsy that they knock over several other things; then a bachelor generally has a horror of sweeping down cobwebs, and they will dangle from the ceiling; but a good housewife never forgets these things.

We found it so in the McCubbin mansion, for there was neatness and order, and then there was a little cherub of a baby, just old enough to double up its fists and make mouths at us.

The baby was quiet enough to allow us to talk bees until near midnight, and we had something near to inspire bee-lore, for Mr. McCubbin was getting his honey ready for market, and had several tons of nice comb honey nicely graded, crated, and stored in his house.

In this portion of California the yield is largely from alfalfa, and at the time of our visit (Nov. 24) the bee-keepers around Selma were getting a fair crop of honey ready for market, while in nearly all of Southern California beemen were pouring sugar syrup into their hives.

The yields from alfalfa are not so great as from sage; but, having a more uniform yield every year, the bee-keepers make fully as much money out of their bees, in the long run, as they do further south—at least, I will make that statement and let it stand until it is proved otherwise.

While the leading honey-plant around Selma is alfalfa, on the "West Side," as they term it,

the sages yield an abundant honey crop; and cases were cited where 500 colonies had given 65 tons of extracted honey; and apiaries with a less number of colonies, yields in proportion.

All the way up the San Joaquin Valley we hear much of the "West Side," and that means the west side of the valley, where it is bounded by the Coast Range of mountains. The east slope of this range seems to have an abundance of sage, while the western slope toward the Pacific, over which we traveled earlier in the season, has but a small acreage of it.

The west side, as we go up the center valley, has a distance varying from 20 to 60 miles.

SALISBURY'S HOUSE-APIARY A SUCCESS.

HOW TO CONSTRUCT ONE.

By F. A. Salisbury.

In the fall of 1893 I built my first house-apiary, and liked it so well during the season of 1894 that I built another out about three miles, near Split Rock. The first view shows how the last one looks from the outside. The whole is on a stone foundation, with five win-

width and runs from the cornice to the sill. First at each end is red; then white; then blue; then yellow; then green.

In the center there is a room 9 feet 4 in. wide, and 12 feet long, the outside of which is painted white. In the center of each color is a window without glass, but with doors 14x20 in., that can be fastened. The hinges used are blind-hinges, and the catches are blind-catches. Along the ridge there is an opening running nearly the whole length of the building, 12 in. wide. Over this is built a roof. When shingled and sided up, the cupola has an opening on each side at the top, of 3 in., running the whole length. In each end of the building there is a door. The entrances are cut through the siding $\frac{1}{2}$ x8 in., and an alighting-board 2x12 in. is nailed just under the opening, even with it.

The second view is an inside one, looking from the center toward one end. On each side you will notice there are two shelves, the bottom one being 8 in. from the floor, and the upper one 53. Doors are placed 15 in. from the shelves. On the shelves the hives are placed 2 feet apart.

The bottom of the hives or shelves proper are

EXTERIOR VIEW OF SALISBURY'S HOUSE-APIARY.

dows in it for ventilation, 6x18 inches. On top of the wall is embedded in the mortar a 2x10 inch; on top of this are placed the joists, 2x10, two feet apart. Beginning at each end, the second one is to be 28 in. from the end to center of stud. The rest to be 24 inches from center to center.

Begin the laying of the floor from each side, laying about two boards; then put up the studs; on top of them the plate, and then the rafters. Studs are placed over the joists, and rafters over the studs. The plate is made of two 2x4-inch studding. Use cove ceiling for the siding. It is painted in five colors. Beginning at each end, each color takes six feet in

so made that the center of each hive is over a space that is open (see the shelf at the right on the bottom). In this space can be placed a board, making a tight bottom; or during the summer months the space can be filled with a frame covered with wire cloth. By using the wire cloth at the bottom the bees are much more comfortable in hot weather, and I think it has a tendency to prevent swarming. During the season of 1894 we had only 11 colonies swarm from 101; this season, only 1 from 114. One would think that the bees would proceed to fill up the wire cloth with propolis; but we have had the screen in use now two seasons, and they are as clean now as when first put

under. We thought they would have to be cleaned at the end of each season, but were pleased to find that they would not. On the left-hand side you will notice that boards are in the open space; these are for use in winter, fall, and spring.

During the honey season we use the wire cloth in its place. By looking closely you will see the grooves in the shelves alongside of each opening; these are for feeding. They are $\frac{5}{8}$ of an inch deep, and $\frac{3}{4}$ wide. Before using they are varnished with shellac varnish to keep them from leaking, and absorbing the feed, thus keeping them tight, sweet, and clean. The hives are placed on the shelves with the

hive; and with two-quart cans there is a capacity of 6 lbs. at each feed. We have found that one can to each colony is sufficient in ordinary cases. Two cans can be used over each groove, and this will give a capacity of 12 lbs. to each colony. It will be much better to have the shelves gotten out by machinery; and if you think of building, I would give the order to the A. I. Root Co. Mine were made by them; and in ordering, mention "sizes given in order 26,542," with two blocks for each hive, 2 in. long, $\frac{1}{2}$ thick and $\frac{3}{4}$ wide. Order 26,542 was for 100 colonies. The blocks are to use in the feeders when not in use, to close up the hole under the hives to keep bees in. Looking

INTERIOR VIEW, SHOWING ONE END OF HOUSE-APIARY.

frames running the same way as the shelf; and as the hives are 20 in. long there is about 4 in. between the ends of the hives. The shelves are 28 inches wide from the siding. The groove for feeding is long enough to run from about 2 in. from the inner edge to nearly across the hive. By using quart Mason fruit-jars you can see at a glance from each end of the building how the food is being taken. In using the grooves, place a piece of wire cloth in the groove close up to the hive, and no bees can come out into the building. Feeding with this arrangement has no terrors, and no robbers can bother. The feeder is always ready at a moment's notice. Two grooves are under each

overhead you see openings in the center, and running the entire length of building, with slides to cover them when not needed.

In the winter and summer months they are always open; in the winter, to keep every thing dry, and in the summer to keep down the temperature and carry off the smoke from the smoker. During the spring months, keep them closed.

The first building built had only three openings, each about 8 in. square. These would not carry off the smoke fast enough, and this building was made so there is ample ventilation. Each opening is 2 feet by 10 in., and are 2 feet apart. All the openings overhead are equal to

one opening 35 feet by 10 inches. The smoke just hustles up and out lively. On the floor there is built a raised floor 12 in. high and 22 in. wide. On each side of this are openings 22 in. long and 6 in. wide every 6 feet. The raised floor begins 6 feet from the door, and runs to 6 feet of the honey-room, which is in the center of the building. No flooring is laid under this raised floor. The honey-room is made tight, and has a door in each end of building. Each end holds 60 colonies. Studs are 2 feet apart from center to center, except the second one from the ends, which are 28 in. from the end. This gives room to handle the corner hives. Rafters are 2x4's, placed exactly over each stud. Collar beams are 9½ feet from the floor, and are also 2x4's. Over the shelf, and nailed to the studs, are boards about 14 in. wide and ¾ in. thick. In the winter there is placed another on the inner edge of the shelf, and these boards make a trough in which is packed chaff or planer-shavings. The building is ceiled overhead. The entire length is 70 feet, and width 12 feet; cost per running foot, \$4.80. or \$336 for the building; all work hired. If you do all the work yourself, the cost would be about \$90.00 less.

DO BEES DISTINGUISH COLORS ?

Bees locate themselves nicely by the colors, very few bees going into the wrong hive or different color. I happened to see something a few days ago that convinced me that bees can tell colors. The north end of the building has no bees in it, but there are 46 in the south end. I noticed that there were bees flying out and in the yellow color in the north end, and thought it was rather funny; thought possibly a new swarm had gone in there. In the south end there was one colony that was flying strongly— young bees out for exercise. They were from the first hive in the yellow toward the north. The bees were also returning, some of them, to the first entrance toward the north in the yellow color in the north end. After the bees in the south end had quieted down, there were no bees going out and in the other in the north end. The entrances were 27 feet apart. This is plain evidence to me that bees can tell colors; and, mind you, they entered the entrance in the north end of the building, and the same relative position of the yellow color, and not any other.

F. A. SALISBURY.

Syracuse, N. Y., Aug. 7.

[When friend Salisbury was visiting us a few months ago he told me something about his house-apary. Knowing that it was a success I requested photos and an article describing it.

I have always felt a little skeptical regarding the ability of bees to distinguish colors; but friend S. gives an incident that shows conclusively that they have this power. In the building of house-aparies I think we shall have to conclude that painting the different parts of the structure in different shades is a necessity. One difficulty with house-aparies heretofore

has been the confusing of the entrances by the bees.—ED.]

BOTTOM STARTERS IN SECTIONS

SOME INSTRUCTIONS TO BEGINNERS.

By Dr. C. C. Miller.

A correspondent writes: "I believe you cut a starter in both bottom and top of the section. I have tried putting in a bottom starter, but the bees always gnaw it down. Can you tell me what to do to prevent this sort of work?"

I believe it may be worth while for me to do more than merely answer the question asked. Possibly I overestimate the importance of a bottom starter, as we are always likely to think well of our own babies. But I know that, since I used bottom starters, I don't have combs break out in sections in shipping as I formerly did. Often, before using bottom starters, a section would be finished up with a space of about half an inch between the comb and the bottom bar of the section; and in transportation such a comb would swing back and forth and break off. Besides, a section looks ever so much better to be filled clear down, and it weighs more.

There is another point in favor of bottom starters for those who have out-aparies that I never thought of till I saw it mentioned in the A B C. A starter that comes down within one-fourth inch of the bottom-bar of the section is inclined to swing in hauling to the out-apary. If the starter is only an inch or so wide it will not swing at all. Just how wide it must be before it commences to swing, I don't know; but I know that a starter that fills the section all but a quarter of an inch will swing a great deal more than one that is three-quarters of an inch less.

In "A Year among the Bees" I say I shall never use bottom starters less than 1 in. deep, and shall experiment to see how much deeper can be used. That's one of the many cases in which I don't know as much as I thought I did. Further experience made me settle down on nothing wider than three-fourths inch for a bottom starter. Wider than that they're in too much danger of toppling over when they become warm with bees on them.

Sometimes bees will gnaw down to bottom starters; but if every thing is just right, there isn't much danger in that direction. If sections are allowed to stay on a hive when there is no need for them, bees are likely to gnaw the foundation, both upper and lower, and the lower seems to have the worst of it. So it's a good plan to take off sections when a dearth comes, even if they be put on again later. Besides gnawing the foundation, the bees daub it with propolis when idle.

Bees are more likely to gnaw very thin foundation, whether it be at top or bottom, and the very thin topples over more easily than that

which has a little more in the shape of side wall. When convenient I like to have the bottom starter of a little heavier foundation than the top.

I always use foundation enough to fill the section all but about a quarter of an inch, and I don't know for certain just what would be the result of using a narrower starter both at the top and bottom; but I suspect that there are times, when honey is not coming in very rapidly, when a bottom starter under a narrow top starter would be gnawed down; whereas one with only a quarter-inch space between the two would be respected. Where there is a big space between the two starters, the bees are more likely to act as if they thought the bottom starter ought to be got out of the way; whereas with only a fourth-inch space between, the bees at once begin to join the two starters, and after that the bottom starter is pretty safe.

To sum up, then, if you don't want bees to gnaw down your bottom starters, don't have too great a space between them and the top starters; don't use for them foundation too thin, and don't let sections stay on the hive when the bees are idle.

KEEPING TOPS OF SECTIONS CLEAN.

A friend thinks there should be some way devised by which the tops of sections in T supers and section-holders can be kept clean. It would certainly be a nice thing if they could be taken off the hive looking as clean as when put on; but I have some doubt whether it will ever be accomplished—that is, so that every section shall be entirely clean under all circumstances; for I've seen many so clean that you'd have to look very close to see that bees had ever been on them.

The only way I know of that you could have sections so that it would be impossible for bees to put glue on them would be to have something solid fitting down perfectly close upon them, and of such weight that bees could not raise it. You can have cloth to fit down close; but the bees can raise the edge, and then little by little they'll raise it more, and you'll have a big pile of bee-glue on top of your sections. You can have what are sometimes called "pattern-slats" over your sections, but it's simply impossible to have them fit so close that the bees can not squeeze glue into the cracks.

On the whole I suspect they are better off with nothing over them, allowing the bees a space above. In the early part of the white-honey harvest, bees don't seem to have the mania for plastering everything with propolis that they develop later. They seem to feel it their duty to glue only cracks and angles; so at such times, if we have one super with nothing but the air-space cover, it will come off clean, while another covered with either cloth or wood will have at least the edges daubed. Later in the season they will varnish a smooth surface

with propolis; but is it desirable to leave sections on then? Possibly, to some extent. But I suspect that a good deal of the daubing of the tops of sections comes from leaving them on the hive when they ought to be off. A section filled and taken off early will be cleaner with nothing over it. If left after the harvest is over, it would be better for a piece of wood over it.

Marengo, Ill.

M. B. HOLMES.

BIOGRAPHICAL SKETCH BY W. S. HOUGH.

The subject of this sketch, Mr. M. B. Holmes, was born in the township of Bastard, Leeds Co., Ontario, July 29, 1853, and is of Irish descent. He commenced bee-keeping in 1882, not by his will and consent aforethought, but by a fortuitous incident, a swarm of bees coming to him in the harvest-field in 1881. [Is it a dream? Was it A. I. Root who, when a boy, had a swarm come to him at a similar time and place, and who gave Pat 50 cents to hive it, thus forming the nucleus of a great and successful apiary?]

M. B. HOLMES.

Mr. Holmes, being of a thoughtful turn of mind, acted on such information as he had time to acquire in the spare hours from the duties of superintending his farm. In six years he had 60 colonies of bees besides considerable sales and 11,000 lbs. of extracted honey. He became a member of the Ontario Bee-keepers' Association in 1884, and has been a director in that organization since that date.

Mr. Holmes, with commendable frankness, admits that reverses came in the shape of severe winter losses. Happily, in this case it was no disaster—simply a reverse, as it could not affect him financially. By carefully working the nucleus system (imported nuclei) he soon regained the lost ground, averaging in 1893 70 lbs. per colony.

I earnestly wish, Mr. Editor, that all would confess their losses in the apiary, and try to explain the cause with the same candor Mr. Holmes has done. It would save many from similar mishaps. But, unfortunately, some bee-keepers have the bump of self-conceit so highly developed that they can't do this. I know a man who would rather confess to doing a mean thing than admit he made a blunder in the apiary. Do you know any such?

Mr. Holmes, actuated by disinterested motives, and at his own expense, attended the session of the committee named by the O. B. K. A. to wait on the Dominion Government at Ottawa concerning the sugar-honey frauds, and to aid, if possible (through the influence of his friends in that place), in securing the passage of a pure-honey bill. He attended the sessions of the North American B. K. A. when it met in Toronto and Brantford, and anticipates a rare treat when it meets again in Toronto.

Ontario sent about 40 tons of honey to the Colonial and Indian Exhibition in 1886, of which he contributed one and a quarter tons. Mr. Holmes has a farm of one hundred and seventy-six acres, four acres of which are under orchard, with commodious buildings, on one side a view of Upper Delta Lake; on the other may be seen a low range of Laurentian hills with dark wood-shaded ravines—a pleasant country home. He owns and lives at leisure in a good brick residence in the handsome and thriving village of Athens, and keeps bees for the pleasure and instruction they impart, as much as from other motives. He is superintendent of the fine Sabbath-school here and an exemplary class-leader. He is also member of the village council, likewise president of the local bee-keepers' association. Gentle and unassuming in manner, he has an unsullied reputation, and holds the respect and enjoys the good opinion of all who know him.

W. S. HOUGH.

HIVE-NUMBERS.

GOOD SUGGESTIONS ON HOW TO MAKE: PAINT TO USE, AND HOW TO LETTER.

By F. A. Gemmell.

Mr. Editor:—I have just finished reading your issue of July 15th, and observed the article of Mr. G. F. Hyde, of San Diego, Cal., also the one of Dr. Miller, in regard to hive-numbers, and what they should be made of, etc.

I never was an advocate of the number being permanently attached to the hive, although I have practiced numbering them, and therefore take the liberty of calling the attention of both those gentlemen, and any others who may think it a good thing to use such, to a sample I now send you, which I have used for some years past, and which has proved not only convenient, but serviceable as well. They are, as

you observe, made of tin, painted on both sides, although one side is all that is really necessary to paint, except that the side next the hive, when not painted, is liable to rust, and at times soil a nice white painted hive. You will observe I have painted the tin a red color. This was partly on account of convenience and partly on account of looks, as it is immaterial what kind of paint is used, so long as a good contrast is made between the lettering and the background. When I use a dark background I always use a white letter on the same, and *vice versa*. I have tried both ways, and prefer the dark background, as I can use white lead for the figures, and it is easier applied with the brush on the stencils than the black or dark-colored paint, and white lead can be purchased thick, and it then needs little if any thinning or diluting. I first cut the tin into strips most suitable and convenient, as to economy, and then paint them two coats of thin paint, as two thin coats on tin appear to me more suitable than one thick coat.

As soon as dry I use a short stubby brush for applying the paint through the stencil, the latter being cut out of very thin brass. I do not make any claim as to cheapness, by making these hive numbers in this way; but I do know they are convenient and serviceable, as they are only temporarily attached to the hive by a small screw having an eye, so that they can be readily secured by a few turns of the naked fingers. One thing is certain—that, after the stencil numbers are purchased, they will last for years in making large quantities.

Stratford, Ont., Can.

MANILLA TAGS FOR NUMBERING HIVES; A SEVERE TEST.

I see in GLEANINGS, July 15, pages 561 and 564, articles on tags for hives. Now, I do not wish to go against Dr. Miller or Mr. Hyde, but I will tell you what I have seen. I have seen manilla cardboard marked with common writing, and also stencil ink, nailed on to water butts and casks, and then a good coat of linseed oil given them. They would be exposed on deck of a sailing ship in a voyage around Cape Horn, of five months' duration, in the winter months. Now, my opinion is, that a card of that kind on a hive would last for years.

GEO. L. VINAL.

Charlton City, Mass., July 28.

[Well, well! perhaps I was a little too fast in concluding, with Dr. Miller, that manilla tags would not do for hive numbers. Dr. M. will please notice that I am considering favorably the manilla in preference to tin. Certainly no severer test could have been applied than the one you mention. Along in the line of this we all remember of having seen similar tags tacked to the side of box cars, and other places, that have probably been there for months and perhaps years. If soaked in linseed oil they will stand any reasonable requirements on the hive.

Yes, here is another one containing some suggestions as to the shape and size of cards. They are all good, and we will try to keep them in mind when preparing cards for another year. Before going ahead we want to know exactly what would be the best and most suitable tag for this purpose, whether of tin or manilla.—ED.]

I see from last issue of GLEANINGS you propose to issue number cards for numbering hives. I have long been in need of such cards to more successfully prosecute my work in my apiary. I am pleased with your proposition to furnish a suitable card. There may be two forms of cards needed—one to be firmly attached to the hive, and the other movable. The figures should be at least one inch in height, on a ground with enough contrast to be easily seen several steps distant. I would suggest the hanging moving card to be $2\frac{1}{2}$ inches square, printed with one-inch figures, to hang by one corner as per sample, of such colors for card and figures as you think best. The stationery card is to be same size, and printed with one-inch figures, etc., as per sample, to be tacked to the hives at corners. Of course, the movable card can be used also for a permanent card by tacking at the corners of the hives, doing away with the extra card, making one card do for both purposes.

J. W. WINDER.

New Orleans, La., July 22.

UNITING BEES.

Question.—As the season of 1895 has been rather unpropitious for the bees in this section, where only white honey is the source of the supply, I find that my colonies have not the necessary number of bees for winter, nor a sufficient amount of stores; hence I ask what I had better do under such circumstances.

Answer.—In all localities where there is any promise of fall flowers yielding honey, the better plan is to wait with the hopes that they may give the bees a chance to build up as to bees and honey; but where there is no prospect of any such yield, as in many localities with which I am acquainted, the sooner the bees are attended to the better. If the colonies were strong in bees, the question might arise whether it would not pay to buy sugar and feed them, so as to have a greater number next spring; but where colonies are both light in bees and in stores there is only one correct solution of the problem, which is to unite the bees till all are strong; and then if stores are still lacking they may be fed. If we are to unite our bees, the next question which will arise is, how best to do it. There have been many plans given for

doing this, some of which are too laborious to be tolerated, such as moving colonies little by little each day till they are brought together, carrying them to the cellar for a few days, etc., the advocates of these plans claiming that, by their use, none of the bees will return to their former location; yet I find that the more simple plans do just as well where a little precaution is taken by way of removing all signs of the former home from the old stand. The two plans which I use, and those which have always worked well with me so far are as follows:

Having decided that certain colonies are to be united, the first thing to know is, which of the two or three, as the case may be, has the most valuable queen. Having ascertained this, I hunt out the poorest one and kill her, then leave them from two to six or eight days, according to the weather and pressure of business. When they are to be united I take the hive or hives, from which the queen has been killed, to the stand of the one they are to be united with. I now select from each hive the frames having the most honey in them, to the number I wish to winter them on, and set them in one of the hives, alternating them as they are set in the hive. In moving the bees they are first smoked thoroughly from the entrance, when they are jarred by placing the hives on a wheelbarrow in no gentle manner, and wheeling them rapidly to the place they are to stand, first having confined the bees to the hive, and doing the whole on some dark cloudy day when the bees are not flying, which causes them to remain on their combs much better in handling them than would be the case were they not thus disturbed, so that, in the process of uniting, very few bees take wing in comparison to what otherwise would, and these few are so bewildered that they immediately go with the others into the new hive, or united colony, as the fanning of wings and hum of the bees calls them, saying, "A new home is found." Having the hive full of combs containing the most honey, I next shake the bees, which are on the remaining frames of combs, off at the entrance, taking one frame from one colony, and the next from another, and so on, so as to mix the bees up as much as possible. When all the bees are inside of the hive, the work of uniting is done. Remove the hives, bottom-boards and all, from the stands occupied by any of the united colonies previous to this, and no loss of bees will occur. What few bees go back to the old stands upon their first flight after this, return after finding their old hives gone; also the mixing-up and jarring process spoken of above causes them to mark their location anew, the same as does a new swarm, or when the bees take their first flight in the spring.

The other plan I use, mostly later in the season, and with smaller colonies, taking the

queens away as before; but when doing this I take all the combs from the hive but the two or three which contain the most honey, the brood all having hatched by this time, and spread these combs about an inch apart, setting them out about two or three inches from the side of the hive, so that the bees may all be clustered on these combs, instead of hanging to the sides or any part of the hive. The hive which is to receive the bees and combs is also to be prepared beforehand, by taking away all the combs but three or four, those being left being the ones having the most honey in them, said combs being placed close to one side of the hive. Having all thus fixed I wait as before for the colonies thus fixed to realize their queenlessness, and till a day occurs when it is from five to ten degrees colder than is required for bees to fly, when I find them all clustered compactly between the spread-apart combs, something as they are in winter. When the right day arrives I light my smoker and put on my veil, for in the following plan described we can not use the hands at times to get off a stinging bee, should one suddenly sting near the eye. I now go to the hive having the queen, and uncover it, giving the bees a little smoke to keep them quiet; and, leaving the hive open, so that I can set other frames right in without hindrance, I go to one of those from which I took the queen, blowing plenty of smoke in at the entrance while I uncover the hive, when more smoke is blown over and around the frames from the top. Quickly set down the smoker and place the two front fingers between the two first frames near their ends, the large fingers between the second and last frames, while the third and little fingers are placed beyond the third frame, when, by closing up the thumbs and all the fingers, the frames with the bees all clustered upon them can be lifted out of the hive at once and carried to the open hive, where they are to stay, and sit down in it all together, close up to the frames of bees that are in this hive. I now go back and get the smoker, and blow enough smoke on the bees to keep them down while I am arranging the frames as I wish them, and adjusting the division-board, if one is needed, fixing all for winter without having scarcely a bee take wing. Should any colony be so strong in bees that a few come out on the sides of the hive, this hive can be placed immediately over the united colony before fixing the frames, when, with a brush and a little smoke, they are easily got into the hive below. Having all in and the hive closed, clear away all that looks like home from the vacated stands, as in the first plan, and the work is done. Both of these plans are very simple, and accomplish just what is desired, the latter being a little the easier where the colonies are small enough so that the bees can all cluster on three combs well spread apart.

SWEET CLOVER ON THE INCREASE.

Although the early rain failed, the latter did not, and July was a month of downpours and showers, and nature rejoices. Sweet clover has been on the increase in this vicinity for a score of years, and has taken possession of the bluffs, gravelly knolls, ravines, gutters, sides of less frequented streets, until its fragrance is everywhere. It is now blooming luxuriantly, and bees are daily working upon its delicate racemes. White clover, dandelions, vervain, and a plant known as butter-and-eggs, are blooming abundantly. I've not seen bees at work on any of them this season.

Bees commenced to swarm Aug. 1, and have their combs built out white. During the drouth I noticed a colony that was weak; but as workmen were busy erecting a house on a lot adjoining, within a few feet of them, I thought it prudent not to disturb them. A swarm came out, and, without clustering, went directly into that hive and were cordially received. How did they know that they were wanted there?

Peoria, Ills.

MRS. L. HARRISON.

LIGHT HONEY CROPS; SWEET CLOVER.

The surplus-honey crop in Northern Illinois will be a light one this year. This is owing mainly to dry weather during the present year and for several previous years. White clover has been virtually destroyed by the dry weather. Unless we have a change in the weather, there is no use of depending on the white clover any more as a honey-plant.

Notwithstanding the loss of white clover, I think I shall be able to report an average surplus of extracted honey this year, of not less than 50 lbs. per colony, spring count. This surplus is mainly from basswood and sweet clover—about as much from one as from the other. This is a small average, as I ought to be able to report an average of at least 100 lbs. surplus per colony from sweet clover alone. I think I could do this if I could control the crop. The crop, as a honey-plant, is destroyed in this locality in two ways—by mowing and by pasturing. The city authorities here mow it down along the streets. This, of course, they have a legal right to do. But as they do not confine their work to sweet clover alone, we honey-producers have no right to complain. And the farmers are busy also in destroying sweet clover as a honey-plant. They have found out that their cattle will eat it; they therefore turn out their cows to pasture upon it when they are short of feed on their farms. They hire a boy to herd their cows and keep them within proper bounds. The cows will eat the plants even

after they come into bloom, and when from 4 to 6 feet high. Some farmers make it a practice to cut it before it comes into bloom, and haul it to their hogs. The plant is then so succulent that hogs will eat it readily. Those who have used it in this way regard it as of great value for hogs alone. There are some farmers here who contend that it will pay to grow sweet clover as a regular farm crop, especially for hogs and cows. If we have many more dry summers they will be driven to it, for sweet clover is one of the crops that will make a satisfactory growth without regard to dry weather. This year, where the pastures are literally burned up, the sweet clover close by is as fresh and rank in growth as could be desired. I have measured individual plants this year that were over eight feet high, and I have seen acres of it from four to six feet high in beds of gravel where nothing else seems to grow.

M. M. BALDRIDGE.

St. Charles, Ill., Aug. 5.

FISH & CO.'S HONEY QUOTATIONS; THE GREAT IMPORTANCE OF SHIPPING CASES WELL MADE.

Mr. Root:—In your issue for Aug. 15, p. 618, Dr. Miller says that strictly fancy comb honey is quoted by one firm at 12 to 13, while another firm, which is S. T. Fish & Co., say, "We anticipate a price of 14 to 15 cts.," and he adds, "I anticipate they'll anticipate a higher price than that before they are flooded with consignments this year."

We believe that Dr. Miller meant no harm to us when he made the above statement; but some people may infer that we are not entitled to having consignments. We advertise in your paper, and we doubt whether you would permit us to advertise if you did not think we were a responsible firm; and we want to say right here, that, any time any man wants to sell us honey, we will pay him the cash for it; but there are times when it is impossible to buy honey, owing to quality and many other arguments that we could advance.

Since you give us this space we want to say that one thing seems to us must be improved in order to further the success of the bee-keeper financially; and that is, they must use a proper package for comb honey. They should not use anything larger than a 24-lb. section-case, and this case ought to be made by the A. I. Root Co. or some firm as capable. We saw some honey from California the other day, that was sold as fancy, that is in a case that makes the honey second grade, as the case is too large for the section; the wood is not of proper material, and is not properly put together. Advertise your cases to everybody, and see that everybody uses them.

One man sent us in some cases painted drab in color. He was under the impression that this would hide the unplanned boards, and might shield the thick wood and heavy nails that he

used. If this honey were in a proper package we could get 15 or 16 cts., while to-day any one can have it at 13 to 14 cts., as it is not in proper shape, and will not sell alongside of fancy.

We received our first consignment of new honey to-day from George S. Scott, Wadena, Ia., put up in 12-lb. cases, three sections being shown through the glass. The shipment weighed 791 lbs., and we sold it at 16 cts. This is as pretty a package of honey as we have ever handled, and we could sell carloads of such goods on arrival, at the outside market price.

Later on, if you care for our opinion we can tell you what we think of the future outlook of the honey situation. Now, we can not tell; but we certainly expect to sell our receipts as per our quotations in your Honey Column, and we must anticipate the price if we had no receipts, and could not report actual sales at the time we sent you the quotations.

Chicago, Aug. 24.

S. T. FISH & CO.

[We should be glad to hear from S. T. Fish & Co. further. We believe they are not only reliable, but alive and active to the interests of the pursuit. It would be well for those bee-keepers who think "home-made" stuff is "just as good, and cheaper," to ponder over carefully the third paragraph above. "Penny wise and pound foolish" fits the case exactly.—ED.]

REDUCING STOCKS, AND UNITING.

I have about 50 hives of bees, and do not wish any more increase. About half of the queens are mated. 1. Would it be a good method to reduce to one-half by killing the mated queens and uniting the hybrid bees with the Italians, and using the empty hives and frames next swarming season? 2. Would it be better to unite in the fall, or early next spring? The colonies are strong; winter loss is nominal here.

R. F. RITCHIE.

Rumford, Va., Aug. 8.

[1. You can do this way providing you wish to reduce stocks; but your hybrids may kill some of your good queens after uniting. 2. Unite in the fall.—ED.]

ANOTHER "COLOR VICTIM."

Another "color victim" wishes to correct one of the errors of last season. I paid a good price for a large noble-looking queen that would be a hummer in a one-frame hive. Her bees are very pretty, resembling some variegated tropical bugs; but I have pinched their mother, and her domain shall be given to one of your queens. I have had my "beautiful" experience; and if you send me a good serviceable queen, raised from an *import*, I care not what color she or her offspring displays.

New Matamoras, O., July 9. W. M. GRAY.

AN INTERNATIONAL BEE-KEEPERS' CONGRESS.

It is proposed to hold an international bee-keepers' congress on the 4th and 5th of December, in Atlanta, during the Cotton States' Exposition. The call has been signed by most

of the prominent bee-keepers in the Southern States, including Texas. At this time of the exposition the railroad rates will be at their lowest, the work in the apiary for the year will be ended, and the bee-keeper will have a grand opportunity to meet and mingle with his brethren in convention, to shake hands, to become acquainted, and talk over questions of vital importance to the success and prosperity of his pursuit. This gathering of bee-keepers will know no lines of latitude or longitude, but will take in the whole American Continent. It is hoped that every live and wide-awake bee-keeper will make his arrangements to meet his brethren on the above days. Subjects of the utmost importance to the continued success of this industry will come up for discussion, in which every bee-keeper in our country should feel the deepest interest.

All the bee-journals and agricultural papers are most respectfully requested to notice the time of this meeting. DR. J. P. H. BROWN.

Augusta, Ga.

BEST HONEY-FLOW FOR YEARS.

We are having the best honey-flow here that we ever had. It commenced about July 8, and still continues. From one colony (the best one I have) I extracted, July 19th, 70 lbs.; and on the 28th of July, from the same colony, I extracted 80 lbs., and in two more days I shall extract about 80 lbs. (16 L. frames) more from them. The honey is very white, gathered from white clover and alfalfa.

J. A. SMITH.

Heber, Utah, Aug. 6.

L. R. D., Kan.—Yes, queens have stings, and sometimes they use them, but only on other queens, and not on bees. In very rare instances they have been known to sting human beings.

C. M. L., Ala.—The instance you relate, of two queens living together in one hive, one the mother and the other the daughter, is quite a common one. As you surmise, the old queen will probably be superseded in a month or so.

J. B. W., Ga.—The longest comb that has ever been made in bee-trees, that I remember to have seen reported, was 9 feet. We have had frequent reports of where they have been 6 and 7 feet long; but even these lengths have been rather extreme.

W. T. T., Mich.—If you desire your bees to swarm, and they refuse to do so, it is probably because the honey season is now about over. I would advise you to practice what is known as "artificial swarming," as described in the A B C of Bee Culture.

F. H. F., Tenn.—The dead drone brood that you sent is evidently immature, and it has been pulled out of the cells by the bees because of the sudden stoppage of honey. If all their worker brood is all right, and drone brood only is found at the entrance, this would be the explanation.

I. S., Mich.—The best way to ship honey is to put it up in large crates, ten or a dozen cases to the crate. The bottom of the crate should contain straw, so as to cushion the cases; and handles should stick out of both ends so that the freight-handlers can easily load and unload the crate.

L. E. A., Minn.—1. If you have honey-dew in the hive it would be well to extract it before winter, and feed the bees sugar syrup. The extracted stuff may be fed them next spring, when it will do them no harm. A better way would be to take out the combs containing the honey-dew, put in frames of foundation, or empty combs, then feed syrup. This will save the expense of extracting, and the trouble of the daub, and give you good combs of stores next spring. 2. Bees may be fed immediately after extracting, and they will repair and clean the combs up in short order. 3. The putting-back of the combs in the former order is not essential. What brood there may be in them should be placed pretty well in the center of the hive; but in the fall we usually do not like to disturb the position, because the bees make what is known as a sort of winter-nest—that is, empty cells massed through the center of the brood-nest, for the bees to cluster on. 4. There is no way of discriminating between beet and cane sugar—at least, on the part of the ordinary bee-keeper. Our own experience shows that one is about as good as the other as a winter feed; but over across the water, a few think the cane is far better. We never found it so.

L. N., Mo.—1. Anywhere from 50 to 75 colonies usually makes enough for one yard. Some localities will support 300 or 400, but they are very scarce. 2. Bees fly on an average about a mile and a half, although they will often go farther, say two miles or two miles and a half; but so long as there is plenty of forage they will not, as a rule, go farther than the first-named distance. Instances are on record where they have gone as far as 7 miles over bodies of water or across a barren stretch of land. 3. One man can not usually take care of more than two or three yards of 50 or 75 colonies each, and even then it is advisable to have a little help during the busy time of the year. 4. A good colony, depending upon the season and the man, will make anywhere from 5 lbs. to 75 lbs. of comb honey; but during the past dry seasons there has been hardly an average of 25 lbs. in the North. Perhaps 25 or 33 per cent should be added to the foregoing figures when extracted honey is under consideration. 5. A good man with a thorough understanding of the business

may increase his colonies by artificial swarming or dividing in connection with feeding, 300 or 400 per cent; but practical bee-keepers do not care so much for increase as for keeping strong what colonies they have. 6. We would advise you to transfer after the honey season. This will give the bees plenty of time to get thoroughly settled in their new quarters.

THE TORONTO CONVENTION, SEPT. 4, 5, 6.

THERE will be representatives there, of course, from the Home of the Honey-bees.

THIS issue numbers 15,000. We shall be sending out a large number of extra copies again during the fall, and our advertisers should not fail to take advantage of these big editions. No more will be charged for advertising rates.

THE fine engraving of crimson clover, on page 658, is a decided improvement in the way of finish over the original; and yet our engravers have followed the details exactly. So far as I can discover, from live specimens we have, the picture is a true representation of the plant. I anticipate that, by another season, there will be hundreds and perhaps thousands of bee-keepers who will be growing it.

THE RAGE FOR GOLDEN BEES STILL ON.

THERE is still, I understand, a large demand for five-banded queens, or, rather, queens that are supposed to produce bees having five bands. Why this is so, in view of their generally reported bad behavior, I can not say, unless it is because bee-keepers are so blind that the *only* desirable point they *can* see in a queen is her ability to produce golden bees. Take them as they run, the average bee-keeper will be far better off without them. I certainly have no antipathy toward them, and certainly none toward those who breed them; but I feel sure they (the yellow bees) will soon go the way of the Cyprian and Holy-Lands that for a time, as our older readers know, had just as great a rage in their favor as the five-banders; and yet for the last few years no one has advertised the Eastern bees, nor does any one know of any breeder who has them for sale.

HOW TO PUT ON BEE-ESCAPES WITHOUT DOING HEAVY LIFTING

is, perhaps, a kink not yet discovered by some. It is easy when you know how. With a screw-driver or strong putty-knife pry loose one end of the super from the brood-chamber. Lift it up just a little way and blow in a little smoke.

With the escape-board right handy, lift up with one hand one end of the super, and tilt it to an angle of 45 degrees. Now slip the escape-board under as far as you can; let the super down on to the board, and then with two hands crowd the board itself squarely over the hive, and finally, in like manner, the super squarely over the escape. This is far easier than lifting the whole super off bodily, setting it on the ground if you can find a place, putting on the escape-board, again lifting the super off the ground and setting it very gently and squarely over the escape-board—if you can. I tell you, it is not easy to hold a hive-super, weighing perhaps 100 lbs., suspended in mid-air, and let it down *easily* and *squarely* over the board. The plan I gave first is, oh so much easier! Try it, if you have not yet learned the knack of it.

DIAGNOSING BROOD-NESTS WITHOUT HANDLING FRAMES.

By the way, if you will not handle frames, did you ever notice that you can judge of the amount of brood a colony may have, by looking at the *under* side of the brood-nest, far better than at the top? The line of honey along the top edge, when bulging out, will often obscure any brood there may be beneath; but not so in the case of the bottom. There are fewer bees there; and the brood, if built down at all, will usually extend down close to the bottom-bars. "But," you will say, "I do not like the fun of lifting hives up to see." Very well, don't do it. Do not stop to pull off the cover, but just pry the hive loose from its bottom-board, and lift up *one end* and peek under. It can be done very quickly, and oftentimes a very satisfactory examination can be made. But when I want to make *sure* I lift off the cover and pull out the center frame, then I have virtually seen the whole hive. But perhaps the other plan may commend itself to some.

A GOOD SUGGESTION—REDUCTION OF MEMBERSHIP FEES TO THE UNION.

I LIKE the suggestion of J. W. Rouse, in the *American Bee Journal* for August 15th, on the subject of the Bee-keepers' Union. After commenting on the proposed reduction of membership fees, he says:

I have another plan to offer, which is, to reduce the membership and annual dues to 25 cts., empowering the secretary to draw on each member for 25 cts. more per year if found necessary. It seems to me this proposition should secure thousands for membership. Now, while, if this plan should be adopted, in making a call for the second 25 cts. some might not respond, the by-laws could be the same as now—where one failed to respond, the benefits to be derived from the Union to cease in his behalf after so long a time after payment of dues should cease, or have failed to be paid.

It seems to me that this is entirely feasible and practicable; and whether the Union be

amalgamated or not, it would be well to carry out the idea. We need the power of *numbers* as a moral backing, and this, it seems to me, would insure the very thing we most need.

THE AMERICAN BEE JOURNAL.

I HAVE sometimes wished that Bro. York were not so good a friend of mine. Why? I have often read with interest the good things in his paper, and have felt like commenting on what he and his correspondents have said; but somehow I have felt that, if I did make such comments, a few (the anti-admiration-society fellows) would say I was doing it to pat "Bro. George" on the back. But really I do not know that this is any *good* reason why I should keep back any thing that I wish to say, if it is deserving.

Well, it seems to me the "Old Reliable" grows better and better as it grows older; and in its 35th year, and in its latest number, we find more good solid matter in it—practical, helpful matter—than at any time in its previous history; and in saying this I do not wish to disparage its past. The articles are well selected, sifted, pruned, and paragraphed. The Question and Answer departments, by Dr. Miller and others, are good. All through I think I can see the evidence of hard, painstaking editorial management.

I shall not attempt to make any sort of review of this or any previous issue; but you know that I said there were several queen-breeders who would or were about to give up the breeding of five-banded queens. Among others that I have mentioned, here is what one of them has to say on page 536, regarding the behavior of some of the cream of the goldens. I give it right here because it seems to be quite in line with what others as well as myself have said of these bees in general of late:

ANOTHER HARD RUB FOR THE FIVE-BANDERS.

I obtained my first five-banded bees from L. L. Hearn, but in a very short time I learned that G. M. Doolittle had given Mr. Hearn his start in these bees. Mr. Hearn's bees proved to be unprofitable, and so the next queens were obtained from the author of "Scientific Queen-rearing." The first queen I obtained, Mr. Doolittle had named "Dandy," for which I paid \$6.00. I introduced her to hatching brood, as the weather was warm, and every thing seemed favorable for a colony of "goldens," as I added a few more frames of hatching brood; but what was my surprise in a couple of weeks to find this fancy queen failing. I then put her into a nucleus and kept her colony weak until autumn. Early in October I put her nucleus into a chaff hive, and gave her plenty of good combs with nice sealed honey, and brood hatching, from a good hearty colony; and, as I knew the bees would not expect much from their queen during the winter, I left them severely alone until early in the spring.

On opening the hive I found a young queen and "Dandy" still at large in the hive. I lifted out a comb with "Dandy" and adhering bees, making a

weak nucleus. In three weeks "Dandy" had disappeared and three queen-cells were started. These were given to a strong colony, made queenless, to feed and complete the cells. Mr. Doolittle sent another to replace her. That was very kind in him; but the second one never filled more than three or four Langstroth frames with brood; and from this queen, and the three reared from "Dandy," I reared 29 queens, nearly all of which I sold for \$2.00 for choice, and \$3.00 for the selected or very best. Some of these queens were sent to Canada, and some to Pennsylvania, some south and west. Some of the old readers will remember that I sent the samples of bees to Thomas G. Newman, then the editor of the *American Bee Journal*. The bees sent showed the sixth yellow segment. Of course, these were picked bees. So far as I can know, and have knowledge, not one of these reared fancy queens produced bees that were hardy enough to come through the winter without adding black stock.

My next breeder was a very yellow one from J. D. Givens, of Texas. This queen kept two or three combs fairly stocked with brood and eggs for about three months, and then was superseded by the bees. I keep bees partly for pleasure and study, and took a fancy to the yellow color; but now I am about dead to the "goldens" though it was a hard death to die.

Last autumn I ordered one more of these queens from Mr. Wood, of Massachusetts, and one from the famous breeder of these bees in Maryland. I gave each plenty of combs with late-hatching bees from hardy blacks. These were packed in a long chaff box containing 11 colonies. One of these colonies died early in the winter. The other was about fizzled when I unpacked them in the spring. The queen was yet alive, and a few black bees, but not a single yellow bee lived through the winter.

But the greatest fault I find with them is the unprolificness of the queens. I never had a colony of them to get populous enough to get the swarming-fever. When these queens mate with hybrid drones, they are some better; but, all in all, the "goldens" ought soon to be a thing of the past, unless they can be improved. W. P. FAYLOR.

TAKING MORE THAN ONE BEE-JOURNAL.

In our last issue I made such extended comments on the *Bee-keepers' Review* that I was really afraid the other journals would think I could see no merit elsewhere. How often have I felt that, instead of making extracts and comments, I should like to publish over again whole articles of the other bee-papers! But that is impossible; but it is possible, with a great majority of our readers, probably, to make a selection of at least three, and buy them at club rates. But, you say, money is scarce. When it has often happened that a single item in any one of the papers has saved the reader *dollars*, can you, dear reader, afford not to take them? Bee-journal editors can scarcely be called rivals. With hardly an exception they "bee" brethren.

OUR BASSWOOD-YARD, ETC.

OWING to ill health and lack of strength to take my usual wheeling-tours this summer, I have been unable to give the out-yard in our

basswood-orchard, run for extracted honey, very close attention; and our apiarist was too busy with the home bees to give very much of his time. The consequence has been, that the out bees have been somewhat neglected, as will appear later on.

On the 21st of August, feeling much better, and strong enough to push a wheel, I took a run down and looked over the bees. Prior to this during the basswood bloom our men had gone down once or twice and put on extra stories, so that there might be room. They were not visited again until I went on the date mentioned; and as I knew they had been storing honey rapidly at the time of putting on the supers, I was not surprised to see the same pretty well filled then.

As I pulled up several supers, and found them crammed full of honey, and saw here and there burr-combs built between the two-stories, and on top of those thick-top-bar frames at that, the thought came to me, "There, W. Z. H. would have the laugh on me if he could be here now, after what I wrote about the scarcity of burr-combs over thick top-bars, on page 636." This was something I had never seen before, and I said to myself, "No, I won't be laughed at yet; there is a cause for it." And, sure enough, in the very instances where burr-combs were built between the two parts of the hives, I discovered that the upper stories were crowded to their *utmost* capacity; no, there was not one cell of room left. What else could the poor bees do than to think in burr-combs in the spaces they are ordinarily supposed to leave clear? You see the facts are here: The apiary, as I have previously explained, had been neglected, and those colonies that had burr-combs had not been given sufficient room in the first place; that is, they greatly exceeded the expectations of the men who put on their supers in the first place. In an apiary properly cared for, no burr-combs would have appeared at all; indeed, there were none — absolutely none — in those hives that were not "clear crammed jam full."

Of course, every bee-keeper knows it is a serious waste to let hives get so full of honey, to say nothing of the tendency to encourage swarming and its attendant loafing. I do not therefore think what I said in regard to the burr combs in question was too strong in apiaries that are *properly cared for*;^{*} and when the bee-keeper himself keeps ahead of the bees, as he always should do, that intolerable nuisance, burr-combs, is done away with.

THOSE FIVE-BANDERS.

In the way of honey, the three-banded leather-colored bees were away ahead; and, oh how much pleasanter to handle! Moreover, the

yellow fellows nosing around in a most disagreeable way, trying here and there to get a sip of honey while I was making an examination.

By the way, we had a bad robbing-spell, I am sorry to confess, at our home yard a few days ago. This is, you know, devoted to queen-rearing; and it seems one of the small nuclei failed to make the proper defense, and before we knew it there was an uproar. It was a most noticeable fact that the leaders in this robbing were the *extra-yellow bees*, and there are only three or four colonies of them now in the whole apiary of over 300 colonies and nuclei. Our Mr. Spafford, who has charge of the home yard, says he wants no more of them, and I am sure I don't; and as a matter of fact we have been getting rid of them as rapidly as possible.

BEE-ESCAPES.

I had a good chance to test the relative merits of the Porter and the Reese escapes. I lifted up the supers, put the escapes on that afternoon, and two days afterward our men called down with a horse and wagon, followed a little later by your humble servant. I was very anxious to see what the escapes would do; and after two days I was a little surprised and a little disappointed to see in some cases that the bees had not all evacuated. But it was noticeable that the Porter gave us the cleanest supers. A little smoking-down finished up the job. The honey was taken off without removing a single frame. The escapes have on previous occasions worked a little more promptly. Why they did not in the present instance, I do not know, unless it was that the colonies were extra strong. In all such instances I put on a super with empty combs or foundation, to afford them clustering-room.

LARGE COLONIES FOR HONEY.

As has been previously the case, the large colonies of two and three eight-framers did altogether the best in honey. Colonies occupying two eight-frame stories generally filled both of them. In some instances they filled two stories, or a story and a half, with surplus extracted honey.

HALF-STORY EXTRACTING-SUPERS.

I was greatly pleased with the working of these supers. They were easy to handle; *i. e.*, to lift, and the queens kept clear of them. In some cases the queens went into the full-depth extracting-supers, but not in one instance did they go into the half-depths; but the bees themselves occupied the one as readily as the other. In fact, they just filled them with honey; and, oh how much pleasanter it was to lift the half-depths, one at a time, to put the bee-escapes under!

It may be well to remark in this connection, that these supers had wide top-bars, and, of course, the queens did not seem inclined to lay

^{*}Are not all the reported cases of burr-combs over thick-tops due to expensive and wasteful overcrowding?

in one or the other with the divided space. Our extracting-supers are not made for brood-chambers, and are not intended for that purpose.

EIGHT VERSUS TEN FRAMES.

There is just one point I want to emphasize again in regard to this discussion. Suppose we admit, for the time being that large hives are better than small ones. I for one would not essay to lift any thing heavier than the eight-frame hive when it is full of honey. I have "broken my back" in lifting such full of honey as it is, and I never want to handle larger brood-chambers. While some people may be strong enough to lift and handle ten and twelve all in one story, I am sure life is too short for me to attempt any thing of the kind so long as two eights accomplish the same result with the (to me) indispensable advantage of being able to handle them one at a time.

Why, when we essayed to carry those single-story eight-frame (full depth) full of honey to the wagon it was all two men could do comfortably, and not very comfortably either, you would say, if you could have seen them screw up their faces.

HUMBUGS AND SWINDLES.

LOOK OUT FOR THEM; HOW AN HONEST BEE-KEEPER WAS SWINDLED.

If everybody could read the sad stories that come to us about the failure of the honey crop, the drouth, floods, and accidents of various kinds, and the stories of the expense and trouble that oftentimes are undergone in getting only a small crop, they would surely feel as I do—that, when the bee-keeper once gets a crop of honey, he should be exceedingly careful not to let it slip through his fingers and fall into the hands of swindlers. The Humbug and Swindle department has been, I believe, rather laid on the shelf of late, especially where it concerns bee-keepers and the honey business; but I am feeling so well now I think I will roll up my sleeves and dare them—nay, I will do more than that; I will hunt them out of their holes, and hold them up to public gaze; and if I can get them behind prison-walls I shall feel happier still, even if it does cost me some money. As an illustration, I am going to give you a little story at full length.

HOW A BEE-KEEPER LOST \$67.80 WORTH OF HONEY.

Friend Root:—Some days ago I wrote your firm that I had sold some honey, and that the parties would send me the money on the 3d of July, when I would remit to you, etc. I waited on them until the 13th, and in the mean time wrote them for the money, \$67.80. I could hear no more from them. On the 13th I went to Memphis, having become uneasy about it. I inclose you one of their letter-heads:

A. M. McLEOD & CO.

Manufacturers of and Dealers in

ALL KINDS OF FANCY PICKLES.

Wholesale Only.
22 Peyton Ave.

CONDIMENTS.
HONEY, JELLIES, ETC.

Memphis, Tenn.,.....189

When I found the place there was no business house of any kind there—only a very small cottage.

I called for A. M. McLeod, or some one of the firm, but an old grey-headed lady came to the door and informed me that A. M. McLeod was out somewhere, and would not be in, probably, before night. I then learned from a near-by grocer that I would probably find him at No. 148 Johnson Ave. I went and found a couple of young men who were very reluctant about giving me any information whatever; said he was not there. They knew nothing of Mr. McLeod's business. After much time and expense I was told to go at once to 148 Johnson Ave., and I would find McLeod there, which I did. He coolly informed me that he had gone out of business and had nothing to pay me with; that he was then at work for that firm on commission. I asked him what he had done with my money. He said he had sold all of it; that a portion was sold on credit, and he had not been able to collect it. I asked what he had done with the money he had taken in, and his answer was that he had an old mother to support, and had to live off the money taken in for the honey. I showed him his letter-head and letters, and asked if he did not know he was a fraud, and was as good as stealing that amount, \$67.80, from me. To cut the matter short, I am beat out of the whole amount, and have no hope of ever getting a dollar of it. The other fellows who are in the deal with McLeod are named Greenwood. When I asked McLeod who were the "Co." part of his concern he coolly said there was no company—that he had put the "Co." to it to make it look bigger. I think they will drop the firm name of McLeod & Co., and use that of another, probably that of the Memphis Pickling and Canning Co., as I saw some honey put up with labels of that sort that I feel sure was some of my money.

R. J. MATHEWS.

Rosedale, Miss., July 20.

We find the above firm quoted both in Dun and Bradstreet. One of them gives the capital as "very moderate," and the other quotes blank. We promptly notified both in regard to this transaction, and have received their thanks.

One big point comes out here sharp and clear: Do not send honey to anybody until you have found out from some bank or otherwise that they are reliable parties. What *they* themselves write to you in regard to their standing, business, etc., is no evidence at all unless they give references to somebody who is known. The fact that they have a letter-head goes a very little way—may be like the case above—only a little cottage out in the suburbs—no company, no capital—nothing but a miserable thieving rascal at the bottom of it all. Of course, we wrote to McLeod & Co., telling them what we should do unless they made some satisfactory arrangement at once with friend Mathews. He writes us below:

I have never heard any thing more from A. M. McLeod. I am almost positive that they are still in the swindle under the name of The Memphis Pickle and Preserve Co. I have seen a letter-head of this company at 148 Johnson Ave. Memphis. There is where I found McLeod, and I am sure I there saw some of my money he swindled me out of, and told them so. I would warn all honey-producers to have nothing to do with them. They ordered a barrel of honey from me a few days ago, saying they wanted the same kind I had sold to McLeod & Co. I can assure you I did not send it.

R. J. MATHEWS.

Rosedale, Miss., Aug. 16.

We can find so such institution as the Memphis Pickle and Preserve Co. quoted at all; so our friend's surmise is probably correct. Now, friends, we are unacquainted with the laws of the State of Tennessee; but if any reader of GLEANINGS in that State will get competent legal advice as to how to proceed, we will have McLeod where he ought to have been long ago, and furnish the money to do it. No wonder they wanted some more honey like that which he sold (?) to McLeod & Co. If this thing is not stopped, all the thieves and pickpockets in the land will be starting a pickle and honey business.—A. I. R.

A VISIT TO DUDLEY ADAMS, PRESIDENT OF THE
HORTICULTURAL SOCIETY OF THE
STATE OF FLORIDA.

While at Lake Dora I visited the beautiful grounds and residence of President Adams. Irving Keck told me I must see that place, sure. Friend Adams is an original enthusiast and experimenter in Florida fruits, and Florida agriculture in general. At present he is taking considerable pains to develop the idea of mulching not only plants but orange and lemon trees, and for some years has been scraping up brush, leaves, weeds, and every thing he can get hold of, to pile it up around his orange-trees, not only that he may cover the ground so as to keep down the weeds, but to keep the soil

come, and also to preserve dampness, the rich soft mold was raked or hoed up so as to cover the stump. Friend Longstreet, who accompanied me on my visit, took the liberty of pulling the dirt away from some of these little mounds, and, sure enough, there were the buds already started. When almost everybody else in Florida was lamenting that there was no budding-wood left in the whole State, friend Adams had a good stock on hand ready to use, and had many of his buds already started. He said to us something like this:

"Like everybody else, I have for years been trying new varieties of oranges; and I had just got to the point where I decided it would be worth a great deal of money to me if my orchard were reduced to four or five kinds, and those just the kinds I wanted, and no other. Providence has helped me to get the thing just where I wanted, and it has also obliged me to make a more thorough job of it than I ever should have thought of doing had not the frost made that tremendous 'move' on us; so you

RESIDENCE OF DUDLEY ADAMS, PRESIDENT OF THE STATE HORTICULTURAL SOCIETY OF
FLORIDA, MT. DORA.

damp, and encourage the formation of nitrogen. Friend Keck informed me that Mr. Adams uses fertilizers as well as the rest, but that fertilizers were scattered all through the leaves, brush, and rubbish of all sorts. I believe this is not quite true, for the grounds are remarkably clean, and free from weeds, in the spaces between the trees where it was possible to cultivate. In fact, notwithstanding the enormous quantity of rubbish in the shape of mulching material on his premises, every thing looked very neat and tidy. Of course, his oranges had suffered with all the rest; and hundreds of great trees, nearly a foot through, had been cut off close to the ground. The day after the freeze, if I remember correctly, he sent a telegram to California, for orange-buds of the varieties he wanted; then as soon as it was certain that a tree was dead or greatly injured, down it went, and buds were put all around on the stump, between the bark and the wood. For protection from another frost that might

see that, instead of lamenting, and counting up my losses, I can really afford to look bright and cheerful in anticipation of the nice new orchard and new fruit that I shall have in a very short time; for nobody knows how quickly a bearing grove of orange-trees may be produced with the great roots to the trees, that are comparatively uninjured."

I have before spoken of the light, airy, well-ventilated Florida homes. The one belonging to President Adams pleased me so much that I begged a photo of it, and I invite your attention to the half-tone copy shown above. I should have stated that his place was situated on one of the beautiful declining slopes toward Lake Tavares. The opposite side of the house is done off with verandas exactly like the one that faces us; and right through the center is a large open hallway where there are rocking-chairs, lounges, and every thing needed for rest (what a nice place for a noonday nap!), with no interruption to the cool breezes. If

the spectator were a little further to the right he would see the beautiful lake through this open hallway. In fact, it would be visible if it were not for the shrubbery on the left. The kitchen, and every thing pertaining to the dining-room, is on the right, as you notice; while the sitting-room, being cut off by that large open hall, makes a nice, cool, and shady retreat; and this sitting-room, or parlor, is finished with specimens of almost all the woods and trees known in Florida, not omitting boards cut from the queer corky-looking palm-trees. A beautiful specimen of the date-palm is seen at the lower left-hand corner; a smaller one on the opposite side of the picture. The veranda on the opposite side is right in full view of the lake, six or eight miles long.

Before leaving, we visited the neat and tidy barns. Of course, such barns are not needed in Florida as we have here at the North. When I asked friend Adams if he had succeeded in growing his own hay and grain, instead of buying from the North, as so many horse-owners in Florida do, he showed me samples of his feed that he had no trouble in securing in great abundance, and he says it is much cheaper than he could get any kind of horse-feed from our great grain-growing Western States. Rice is one of his favorite products for feed; and he cuts it just before the grain is fully mature, so it can be stored and fed out in the bundle, giving the animals both grain and hay at one and the same operation. In fact, our whole visit was really refreshing. You may remember that the state of agriculture in Florida at the time of my visit was such that almost any one would be considered excusable for feeling discouraged; but to find a man who saw openings for great results in almost every direction, and one who could rejoice that even the frost had done a great work for him, was really worth while; and the Florida Horticultural Society has done wisely in selecting such a man as their leader. One unconsciously begins to wonder, as he looks over such a place, whether it is really possible for the average man to succeed so well, even if he tries ever so hard. Well, I presume it is true that God does give special gifts to some; but I am sure of this also, that a good many people do not try as hard as they might. The longer I live, the more I am convinced that brainwork, and making one's business a constant study, both day and night, has more to do with success than almost any thing else. I see a world of people around me who stumble along thoughtlessly and indifferently. God's gifts are rushing past them in every direction. In fact, they oftentimes stumble over them; and when you call their attention to it they deliberately inform you they have not noticed or have not seen any thing of the sort which you describe. And then I think of the text, "Knock, and it shall be opened unto you; seek, and ye shall find." I see people all around me—not only boys but grown-up men—who have not any comprehension of what is going on around them. They tug away at grievous burdens. An empty wagon is going in the same direction, but they do not see it, and never will see it; and sometimes it transpires that the empty wagon belongs to the very man they are working for, and this very man is anxiously waiting for them to hurry up.

At Lake Helen I made a very brief call on our good friend G. W. Webster. In his doorway I found guavas perfectly protected through the freezes, by being simply bent down and covered with straw and leaves, and afterward with a bank of dirt. In the same way he had saved some choice varieties of the Japan

persimmons. During the previous season he had produced specimens weighing 18 ounces, and $4\frac{1}{4}$ inches in diameter. These great luscious fruits, without seed or core, readily sold at a nickel apiece; and a persimmon-tree will bear more fruit on a given expanse of limb than any other fruit-tree I ever saw or heard of; that is, if you hold up the branches so the weight of the fruit will not break the tree to pieces.

OUR FOOD AND DRINK: ITS RELATION TO DISEASE.

THE SALISBURY METHOD OF MANAGING DISEASE.

Prove thy servants, I beseech thee, ten days; and let them give us pulse to eat, and water to drink, then let our countenances be looked upon.—DAN. 1: 12, 13.

And in all matters of wisdom and understanding, that the king inquired of them, he found them ten times better than all the magicians and astrologers that were in all his realm.—DAN. 1: 20.

To him that overcometh will I grant to sit with me in my throne.—REV. 3: 21.

During the convention in St. Joseph, Mo., last October, as you may remember, Ernest was left at home to look after business, in the absence of myself and Mr. Calvert. In a very few days, however, his health failed; and from that time on he seemed to be the unfortunate victim of grip, nervous chills, or something that the doctors hardly knew what to do with. One physician after another was called; but in spite of them all he seemed to be going into a decline. Even wheel-riding did not seem to bring him up as formerly, principally from the fact that he could not stand the wind. Even a moderate breeze gave him chills, neuralgia, etc.; and when the wind was in the north or northeast he was absolutely obliged to stay indoors; and a good deal of the time he could only lie on the sofa or wait for a still day. A good many of us settled down to the opinion that it was only another phase of that terrible disease which has been called the "grip." You may remember that, for three or four years past, I have been battling with something similar a good deal of the time, no matter whether I was in California, Ohio, or even down in sunny Florida. In my case the general decision was that it was in consequence of overwork; besides, I was getting pretty well along in life; but for a young man only a little over thirty, it seemed very strange, and withal very sad, that he should, as it were, "play out" right almost in his youth. Of course, much speculating was done in regard to this, that, and the other remedy. Different localities were talked about, and various sanitariums.

As some of the clerks in the office, and one of the teachers in our Medina schools, had been very successful with what is called the Salisbury treatment, or lean-meat diet, this was talked about more or less. Perhaps I might here devote a little time to an explanation. In our little circular in regard to the water cure applied internally, occurs the following sentence:

At different times the use of water in large quantities, taken into the system by way of the mouth, has had its advocates. Dr. Salisbury has for many years been accomplishing a good deal by "feeding" his patients on hot water.

But it seems that Dr. Salisbury or some of his friends ran across this; for in GLEANINGS for July 1, 1891, occurs the following:

DR. SALISBURY'S METHOD OF TREATING DISEASE, AND HIS USE OF HOT WATER.

MR. Root:—In your article, "A New Method of Treating Disease Without Medicine," in GLEAN-

INGS of March 1, there is a brief allusion to Dr. Salisbury's method, which is somewhat inaccurate. It is quite true that the doctor has accomplished and is still accomplishing much for suffering humanity, but he doesn't feed his patients on hot water. In his system the hot water is used solely for flushing the stomach and intestines, cleansing the former from slimy, pasty growths, which interfere with good digestion, and the latter from feculent deposits. To feed his patients, the doctor prescribes beef—lean steak, free from fat and gristle, reduced to a mince meat in a chopper, and then pressed into cakes or meat balls, and then broiled. According to Dr. Salisbury's theory, man is two-thirds carnivorous and one-third herbivorous; and his food should follow the same proportion. In some countries—India for example—the people, in the course of generations, have become herbivorous, and are able to live on a purely vegetable diet; but, few people can digest a purely vegetable or farinaceous diet in the United States. The doctor holds that most diseases are caused by a long course of eating improper foods which ferment in the stomach or bowels, and do not properly digest. His remedy is, first, to wash away offending and offensive matters by taking a pint or more of hot water at about a temperature of 110°, an hour before each meal, and the same interval before bedtime. Then he prescribes an exclusive meat diet, or as nearly exclusive as the patient can take it, forbidding sugary, starchy foods, and any thing prone to easy fermentation. Medicine is given, if necessary to help digestion. With good digestion the system begins to make good blood; and with a supply of good blood, all the organs of the body perform their functions well, and normal health is restored. This, of course, is not done in a day, for nature works slowly, and the result of a long course of wrong living can not be corrected by a short course of right living. In the case of serious diseases, like, for instance, consumption, it takes probably a year or two of treatment to get thoroughly well; but the improvement usually begins at once; and the end, if slow, is pretty certain.

The doctor's plan, you see, differs from the one you describe, in that it is more extensive—flushing the whole of the internal man, and not simply the colon, though the latter is good so far as it goes—and more natural.

It may interest some of your readers to know that Dr. Salisbury is an Ohio man, hailing, I believe, from Cleveland, though now living in New York, at 170 W. 59th St. E. CONNOLLY.

New York, March 7, 1891.

Our readers may remember that, in my reply to the above letter, I expressed some doubt in regard to the absolute necessity of coming down to a pure meat diet. I did it, notwithstanding Dr. Salisbury, some twenty-five years before that, brought me out of what might be called a rather precarious state of health resulting from too close application to the office.

Well, after Ernest had become a good deal discouraged, the rest of us as well as himself decided he ought to go down to Cleveland and see Dr. Lewis, who now represents the Salisbury method in that city.* For long weeks his diet was lean meat almost exclusively; but just about when I began to fear that he was suffering, and depriving himself needlessly, especially after being reduced in flesh from 140 to 120 lbs., I noticed that he was gradually getting indifferent to wind or weather. He would even stand out in his dooryard, with the thinnest clothing on, while I was muffled up in woolen clothes and sealskin cap, with a big flannel pad across my chest, etc. In spite of all this padding and clothing, however, I could not stand the north wind. While superintending the laying of some water-pipes I caught the toothache; then neuralgia all over my face; then earache, with chills accompanying,

and I was feeling pretty miserable. He and the rest of the children, including Mrs. Root, began to suggest the old Salisbury treatment. But I dreaded even the thought of it. I told Ernest that, when I came into his home, one day, and smelled the broiling steak, so familiar in years gone by, I almost felt as if I could cry for him, if it would do any good.

Before I got over my attack of neuralgia, however, he came into our home one day, and found me leaning over a hot stove, bathing my face and teeth with physianthropic (see page 537), and shedding some bitter tears (on my own account), even in spite of myself. I told him it was just grip I got from that northeast wind. By the way, one day I noticed the thermometer registered 80 degrees in the shade, and I was bundled up as I have described, and still I was cold. "Where was the wheel?" do you ask? Well, could I have been spared to ride 20 miles or more on the wheel every day, or even every other day, I might have got along tolerably well; but there was one trouble I have frequently referred to, that even the wheel did not cure. It is a sort of chronic dysentery, accompanied by distress in the lower intestines, etc. I have mentioned one severe attack of it while I was in Florida. This latter trouble seemed to be gradually gaining ground. Now if you will pardon me for speaking so much of my ailments and troubles I will try to get on to a pleasanter theme.

Ernest urged that I should at least go and see Dr. Lewis, and have him look me over, examine my blood under the microscope, etc., and tell me what he thought. I did not propose to take the treatment, mind you, but I consented, just for the fun of the thing, to go and talk with the doctor. Well, the doctor said if my trouble went on I should soon have consumption of the bowels; or, to put it in plain terms that everybody can understand, he said that my disease was fast settling into a chronic case of "hog cholera." I do not suppose that he meant that I had been greedy in my eating. He admitted that, if I could be spared to ride the wheel, and take things easy, keeping clear of business, I might do very well without any treatment; but if, on the contrary, I would give my intestines a rest till they could be cured up, and then be careful as to what I ate, I might go on with business, and at 55 years of age be just in my prime for good downright hard work in the office or anywhere else.

"But how about the chills, neuralgia, etc., doctor?"

"These are a secondary matter—a result—a trifling thing, in fact. If you undertake the treatment we will have off that overcoat and fur cap in less than ten days."

"But, doctor, suppose the wind should be in the northeast?"

"I don't care where the wind is. In less than ten days we can have you wearing ordinary clothing."

"Why, look here, doctor, if you can get me rid of my chills and neuralgia and toothache and earache, so that I shall not need to bundle up when there is a brisk north wind, I will undergo almost every thing you say—for at least ten days, any way."

At the time, I fully intended to submit to the treatment ten days and no more; but the doctor and Ernest exchanged glances, however, and made preparations for a siege of about three weeks, as I afterward learned. The whole family were greatly pleased, and entered with much spirit and enthusiasm into the plans for getting papa well and strong. Let me explain a little more minutely right here the program that has been settled down on after

* Dr. J. M. Lewis was for ten years a partner of Salisbury; and he said to me, but a few days ago, that, in his opinion, Dr. S. has done more than any other man to get the whole medical fraternity out of the ruts and superstitions that have for ages hindered and cramped all progress.

the past twenty-five years of experimenting and study:

You go to the butcher's and get some of his very best round steak. Wait till he has sliced off the shoulder until he gets down to where the bone is small. Tell him to cut you a slice fully an inch thick. Now remove all fat, gristle, and every thing but lean meat. Get an Enterprise meat-grinder, small size, with recent improvements. Put the lean meat through three times; and then have it cooked on any good gridiron, or even with the five-cent wire meat-broilers, to be had in every counter store. The patient is to take the meat hot, just as it comes from the fire. Season with salt, pepper, and a little butter. Decide by experiment how much you can eat and digest thoroughly, and have that fixed quantity at every meal. I began with $6\frac{1}{2}$ ounces three times a day. Six ounces would have been hardly enough, and 7 ounces is a little too much. Thus you see there is no possible overloading of the stomach or digestive organs. As you progress, increase the amount gradually until you can take 10, 12, and even up to 16 ounces or more. Your meat is to be taken at regular hours. You probably will not forget when it is time to have your regular rations.

I soon found that my weakest spell was in the morning, because I got up a little after five and start several kinds of business before John and Ernest get around. On this account I have three ounces of beef at 10 o'clock, besides my three other rations. I go to bed at half-past 8 or 9, and sleep soundly—more so than I ever did before—until Mrs. Root wakes me at 10 o'clock. This 10 o'clock meal prevents me from getting faint in the morning before my regular meal at half-past 6. Now, please notice I do not have a crumb of bread, a particle of fruit or vegetables—no sugar, not a drop of milk in the half-cup of tea I am permitted to have with my meat. Right here I presume a part of my readers—may be nine-tenths of them—will say, "Oh! get out with your lean-meat diet to the exclusion of fruits, milk, and honey. Brother Root, we shall think you are the worst crank there is going if you continue to talk such nonsense." Hold steady, friends. If you are well and warm, and your food agrees with you, by all means eat the fruit and milk and honey, and thank God for them. If you are a dyspeptic, and especially wedded to nervous chills as I have been, I think you had better listen a little further. Lean meat is almost the only article of food that is digested entirely in the stomach. Look it up in your physiologies, if you think I am wrong. Where one has chronic dyspepsia, or a tendency toward chronic dysentery, his life may depend upon giving the lower intestines a rest. Vacations are very fashionable nowadays; in fact, they seem to be the rage almost everywhere. Why not give your digestive apparatus a vacation, or at least that part of it? I believe the thing is entirely possible. From the very first meal of this pulverized or rasped beef, as you might term it, my bowels began to feel rested. The hubbub and turmoil and distress stopped *right away*. In fact, for weeks past I should not have known I had any "insides" at all, so far as any sensation is concerned. The effect was really marvelous. I should not have thought it possible had I not tried it.

Let us now consider the drink part. I will repeat a part of the conversation the doctor and I had together.

"Why, doctor, I did not know you restricted your patients to the amount of lean beef they must eat. Dr. Salisbury used to tell me to eat a pound at a meal if I could; and I did succeed in eating a pound just as it comes from the butcher."

"Well, that might have done for you 25 years ago, but I think we have a better way now. You must not overeat, even with lean meat."

"But, doctor, I can have all the pure water I want to drink, can I not?"

"You can at stated periods. Three hours after any or every meal you may drink all the water you choose, but no cold water. Take it as hot as you can drink it conveniently. I should like to have you drink at least a pint—a quart would be better. The first thing to be done is to wash and cleanse and rinse your whole digestive apparatus. You want to bathe it out thoroughly every day, and four times every day if you can. If you can not have your hot water within $2\frac{1}{2}$ or 3 hours after each meal, and, say, an hour or an hour and a half before getting a meal, then skip it—don't have it at all. Your beefsteak will be digested and out of the stomach in from $2\frac{1}{2}$ to 3 hours. If you drink the water sooner, or drink very much during your meals, you will dilute the gastric juice, and hinder or stop digestion. Cold water especially will do this at your stage of the disease. You may have noticed it."

I told him that I had for years been deciding I could not drink cold water during mealtime; and I felt better to take almost no liquid at all. I had also learned that water (especially ice water) within, say, an hour after my meals, stopped digestion, and gave me much distress. I told him how often I had been parched with thirst during attacks of dysentery, but did not dare to drink a drop, as it was so sure to distress me. He told me I would find at such times I could drink hot water—as hot as it could be taken into the mouth—without any distress; and I then remembered that, while in Florida, a friend persuaded me to try drinking a good lot of hot water as a remedy. Strangely enough it gave me almost immediate relief.

You may be a little surprised to find that one very soon learns to relish hot water. At first I thought it would be more palatable with acid phosphate or a little ginger, or something of that kind, added to give it flavor; but now I greatly enjoy my pint or quart of pure soft hot water four times a day. I take the first dose at five o'clock in the morning, so as to get it an hour and a half before my breakfast.

In a recent number of the *Ohio Farmer* a writer suggests that horses will do a greater amount of work if a heavy watering is given at 10 o'clock in the forenoon, and between 3 and 4 in the afternoon. He says horses so treated will keep in flesh and strength with less food. I suppose another watering the last thing at night would be in proper order. Give them a little between times if you choose; but let them do the main part of their drinking, as nearly as you can, midway between feeding-times—leaning, of course, a little toward the coming feed, and a little further from the last one. By the way, this hot-water treatment is now so generally known and adopted by people in poor health that perhaps this explanation is hardly needed. I thought it a little hard when the doctor said I must not drink at springs and wells on my wheel-rides. If I continue riding, perhaps these drinks of even cold water would do but very little harm; but I am inclined to think now that hot water at pretty nearly the times mentioned would be much safer and better. Oh! I forgot to mention that, in about four days, I began to dispense with my extra clothing, and the neuralgia and cold in my head suddenly disappeared in a very unexpected way. In a week I was around in my shirtsleeves; in ten days I put on thinner clothing, and dispensed with the flannel chest-protector that I

had worn winter and summer almost constantly for three or four years.

You will recollect that, in our text, Daniel asked of his keeper that he and his friends might be proved ten days. Thus we have Bible authority to the effect that ten days of pure simple diet may bring about a material and perceptible change in one's health. When Dr. Lewis said he would cure my chronic chills in *ten days* I don't suppose he thought of Daniel and my text. Let me digress a little.

Some years ago a writer in the *Scientific American*—and I believe the article was also copied in various papers—took the ground that colds are caused by disordered digestion; and the remarkable thing about the article was that the writer said that, when his diet was right (and I presume that included drink as well), you could not make him "catch cold." He even went so far as to prove his position by public tests. He slept in damp bedding; he went out till drenched through with rain, and then stood in a draft until his teeth chattered; went about with wet feet—did every thing, in fact, that old established rules have laid down as particularly dangerous in this line, but he took no cold at all. He got cold, of course, and suffered for the time being; but when he was warmed up again, no after-consequences followed. This writer has since published a book on health, and I have studied it with much interest, but I can not lay my hand on it now. He did not prescribe the lean-meat diet particularly; but he advised such a course of eating and drinking as to seem to be conducive to wholesome digestion. Well, for years past, whenever I came in to sit down at the table, the doors and windows would have to be closed a good deal of the time in hot weather, or I could not stand it. Mrs. Root and the children have suffered for want of the (to them) delicious cooling breezes, just because papa could not stand a draft; but now I am rejoicing, during my fourth week with the treatment, in being able to wear thinner clothing than any of them; and I can stand as much draft as anybody I know of, or more. Windy days that have been, in fact, my deadly enemy, now seem delicious and nice; and it really seems as if I couldn't catch cold, even if I tried to. Of course, I am not positive that this thing will continue; but if it does, it is worth to me a big lot, not only for myself, but that I may point out the way of escape to others who are suffering from hay fever, neuralgia, and feeble vitality in a thousand and one directions.

You may remember that, in my pamphlet on the internal water cure, I suggested that the too frequent use of the hot-water injections is apt to remove the food before the process of digestion is complete; that in this case I had discovered there was a marked loss of strength, from which I inferred that the lower intestines, and may be even the lower colon, perform a part in the operation of digesting the food, and take from it something important, and possessing much nutriment; and that a loss of this results in a loss of strength. Now, letting the stomach do all the work, and leaving the intestines and colon to "take a vacation," as I have expressed it, produces just this result. In a few days you find yourself feeling remarkably clean and light, and perhaps rather "flat," and at the same time you find your strength oozing out, and a faintness or weakness you never felt before, taking its place. I told the doctor I felt as if I imagined Samson did when they had cut off his hair. This is the discouraging period in the treatment. I suppose a good many patients turn about and go back, as did Christian's companion in *Pilgrim's Progress*. Be of good cheer, friends; do not be in haste to give up. Prof. Cook once told us in a lecture, that, so great is

the effort nature will make to sustain life, a man could have his whole stomach cut out; and if the connecting tubes were hitched together, the other organs would do their work until nature could manufacture another stomach. We often see the same thing in nature. When the animal economy begins to understand the different order of things, the stomach pretty soon learns to do double service, just as a blind man sees with his ears, and just as a deaf man hears with his eyes. When this lassitude and weakness comes on, lie down and rest. Take it patiently, and it will often go away in a short time. My remedy is a nap, and my naps are as regular before dinner and supper as the meals themselves—that is, when at home and at work. I have recently found that my wheel will usually drive off this weakness.

A few days ago I asked the doctor if he expected me to be able to ride the wheel on lean meat alone.

"Why, bless your heart, yes. If you can hold out until we are out of the woods you will ride your wheel with muscles of iron, and muscles that almost know not fatigue."

I have now been almost four weeks under the treatment. For two weeks I felt as if I had not strength to ride more than half a mile. Three days ago I tried a couple of miles; then about five miles; and day before yesterday (Aug. 15), about eight miles; and last evening, the 16th (the mercury had been in the 90's all day), I rode *twenty* miles after supper; and I came home just running up the hills, because I enjoyed it.

Now just a word in regard to our texts and the moral of the case. I never before heard anybody so emphatic against the use of wine and beer as was Dr. Lewis. He said that, if alcoholic stimulants were really needed, it is better to use pure whisky, brandy, or even alcohol itself, and not beer or wine, that can only start a ferment in the bowels, when such ferments are already the cause of the greater part of the sickness of the present day.*

Again, the person who has learned to forego luscious fruits and vegetables, and hold right on steady, with nothing to vary the monotony of the invariable lean meat, will not find it difficult to control himself in every other way. The mental and spiritual drill that one learns from such tremendous self-denial ought to last him through life. The "pulse" mentioned in the book of Daniel was probably not lean meat,

*Thousands of people are probably suffering and dying almost every day by a kind of slow starvation, from the fact that their food ferments and sours in the digestive apparatus, instead of furnishing good healthy material for the blood to build up the system. In fact, the digestive apparatus gets to be a sort of brewery, manufacturing beer and carbonic-acid gas from every thing taken into the stomach, especially food that contains starch and sugar. Most of you have had occasional experiences in this line with disordered stomach and bowels. Well, there are still doctors left who will tell patients suffering in this way to drink *beer* or *ale*, to give them *strength*. Adding beer and fermented liquors when the stomach and intestines are a regular brewery already? What sense or what consistency is there in that? And this very Hires' root beer, that is puffed so much, even in our best papers and periodicals, is only a milder mixture of yeast and sugar. Read the directions—3 lbs. of sugar to a gallon, and then a great lot of yeast to make it ferment. And, by the way, some of the Hires' root beer, when the yeast is tiptop and every thing just right to make "good beer," contains enough alcohol to make one who is sensitive to its influence feel its effect very distinctly. I suppose, if the W. C. T. U. should undertake to make a protest in this direction they would stir up a hornets' nest. Be of good cheer, friends. Dr. Salisbury and Dr. Lewis have been for years protesting and proclaiming cautions against this very thing.

but it was a pure simple diet. Be that as it may, the thing that Daniel and his friends objected to (wine) is the very thing Dr. Lewis so positively forbids. Very likely they had pulse to eat and water to drink, each at regular intervals. With such treatment there is no such thing as overloading the stomach. There is no question nor speculation as to whether this, that, or the other is good for you or causes you distress. If our people had perfect control of all their appetites, their tastes, and their passions, this world of ours would be a heaven below. Do you doubt it? Read the last of my three texts—that grand Bible promise: “To him that overcometh, to him will I grant to sit with me in my throne.”

A friend said to me only yesterday, “Mr. Root, I have been sick for two days, and it is a good deal your fault.”

Of course, this was pleasantry. He went on: “I knew I ought not to eat watermelons; but we had one that was so very nice I could not resist the temptation, but kept on eating. Then we had some of that new kind of beans of yours—the Best of All—and they were so exceedingly luscious, and hit the spot so exactly, I ate more of them than I ought to. It took me about two days, and required some medicine, before I was straightened out again.”

How many such cases do you suppose there are in this world of ours? Now, the point is, one who has gone through this ordeal that I have pointed out to you would not be very likely to lose his health, and get back again into the slough of despond. I remembered so well my experience during those 18 weeks 25 years ago that I could thank God for my daily bread at almost every meal since that time with a new understanding of the matter. We never prize God's blessings until we have been deprived of them. We never prize health until we have had some experience with sickness. These bodies of ours are a sacred charge intrusted to us by the great Father of all, and he expects us to take good care of them. He expects reason to hold in check the passions and the appetites under all circumstances whatever. If we disregard Reason, and set her admonitions at naught, then we have got to go back and live a life of self-sacrifice, and even total abstinence from many things that we might otherwise enjoy with impunity.

Is it really a method of healing diseases without medicine? To a certain extent I think it is; but Dr. Lewis told me it would be very much better if the matter were looked after under the charge of the regular family physician. He said the family physician could engineer the patient clear through without any difficulty at all if he only *would*. The difficulty is, he may not himself have faith in it; and then, again, it is not a very pleasant or taking method of treating disease. The average physician knows this perfectly well, from the experience he has had in undertaking to get his patients to leave off tobacco, tea, and coffee, extravagant use of sweets, etc. Like the faithful pastor who preaches plain truth, it may sometimes cut off his salary a trifle, for the time being. Again, the family doctor, to obtain the best results, should be able to examine the blood, the urine, the secretions, etc. The principal difficulty to be met is that of constipation, which is almost sure to follow. Now, I have spoken exceedingly plain before on these pages in regard to this matter of curing disease without medicine, and I am sure our friends—at least the ailing ones—will pardon me right here if I speak so that I may be clearly understood in this matter. With the pure lean-meat diet there is no need of a movement

of the bowels oftener than two or three times in a week.* On one occasion, when I had gone four days, Ernest took the responsibility of giving me one of his favorite pills. He asked Dr. Lewis afterward what he thought about it, and the latter replied: “Oh! no, no! Pills may do for *you*, but no pills for your father.”

You see, after my tendency to chronic dysentery, taking pills is like waking up the baby after you have walked the floor with her for hours to get her to sleep.

“Well, doctor, if I can not take pills or physic, what am I to do?”

“Why, just take a tablespoonful of castor-oil before you go to bed. If one tablespoonful does not answer, try two. Castor-oil will lubricate and soothe those long-suffering intestines, rather than rasp them up again as physic does.”

Now, if you call castor-oil medicine, then my talk to-day is not exactly doctoring without medicine. I believe that, with many patients, both Lewis and Salisbury are in the habit of giving some sort of tonic before the meal, and a preparation of pepsin so as to assist digestion after the meal. Ordinarily, pure fresh lean meat and pure water are all that is needed—“pulse to eat, and water to drink;” and, dear reader, if you will prove it ten days, as did Daniel and his little band, I think you may not only be wiser and brighter, and clearer in intellect, but you may also see your way out of troubles that have followed you for years.

Just a word, before closing, in regard to the manner of cooking this ground-up beefsteak. It must not be fried or browned, for that spoils its digestibility. It should be broiled, and the broiling must be done just right, so it will be juicy, soft, and rich. There is on Euclid St., Cleveland, O., a place called the “diet-house,” where they have made it their business to cook meat for the Salisbury patients for 25 years or more. As they cook it, it is about the most delicious and strength-giving article of food I ever tasted. After eating 10 ounces a few days ago, I felt as well satisfied as if I had had the best meal that could be furnished in that great city. I bought some of the very same beef, of the very same butcher; but after I got home we found it was quite a little piece of skill to cook it exactly as they did at the diet-house. But Ernest finally mastered it. The secret is in having it cooked alike all the way through, and be sure not to have any portion of it overdone. If right, it will be juicy, soft, and toothsome, requiring very little chewing; and from it strength and energy come very quickly to the oftentimes weak and hungry patient.

*May I in this little footnote be pardoned for speaking still more plainly? I am now in my fourth week, and my bowels move without any castor-oil or anything else but a mild hot-water injection, without the least bit of pain; and, most astonishing of all, the small amount of residue left after perfect digestion is absolutely *without smell*. Ever since I was a child I have wondered again and again why it was that human beings should necessarily have any thing to do with almost the foulest substance that one can well imagine. Is it right, and is it God's will, that we who are called the temples of the Holy Ghost should have any thing about us at any time so offensive and repulsive to every refined thought and feeling? and it rejoices my heart, to know that it is even possible for one to have a sweet breath, a sweet-smelling body, and to be sweet and clean always and everywhere. You see this talk is only a continuation of my talk years ago under the head of my favorite little text, “Wash ye, make you clean.”

ALFALFA—ON THE WHEEL.

There is not going to be much "On the Wheel" in this issue, for the beefsteak diet has sort o' knocked it out. But that trip of twenty miles that I made after supper was to see a little patch of alfalfa right here in Medina Co., that stood a couple of feet high, on the 16th of August, and it has already given two heavy cuttings this season. The owner said it stood fully three feet high when it was cut, and gave the most feed, and about the best feed, of any thing he had ever taken from a like piece of ground. The seed was put in two years ago in June, therefore it had stood two of our Ohio winters, and the last one, perhaps, the worst in fifty years. He said that, after our spring frosts, he thought at one time it was entirely killed; but finally he could see a little green shoot here and there, and finally it all started, and grew and grew. This is on ordinary Medina clay soil, perhaps with a little tendency toward sand or gravel. But if one man can make such a success as that on a quarter of an acre, why can't somebody else do as well? I confess it has given me the alfalfa fever already.

WATER-WITCHING.

QUITE a good many communications have come in, and several have invited me to come and see the genuineness of the thing proved. One man has been on our grounds. It is *barely possible* there is some science about it, but there is certainly a good deal of folly and superstition mixed up with it. For instance, one friend claims it is due to electrical attraction, and says that, if the peach-tree branch be wrapped in a silk handkerchief, it will not work. Those versed in electrical attraction or magnetic attraction will at once recognize that this is a mistake. A silk handkerchief has no power whatever over magnetic attraction, as any one can readily prove with a cheap magnet and a common pocket-compass. Again, another friend assures us that blindfolding the operator will not answer, for he says the switch will not indicate water unless the operator can use his eyes and see his switch. We have heard of human beings who would not work unless you kept your eye on them; but I do not know that I ever before heard of a *machine* that refused to "go" unless the owner kept it all the time exactly under his sight. You see this runs us into the occult sciences again. Clairvoyance is not yet recognized as a force in nature or as one of the sciences. A. I. R.

Special Notices.

GARDENING FOR SEPTEMBER

We are now having rains quite frequently; and on ground that is kept mellowed up, they seem sufficient; but where the ground has once become baked and hard, so the water runs off, the drouth seems to continue; and on such ground as this, trees and small fruits are still dying. The water has not yet got down to their roots.

Our Best of All snap bean is proving to be true to name as a shell bean. In fact, some of the friends pronounce it ahead of any of the big limas. The only trouble with it is, it is a colored bean; but when I was a juvenile I remember of eating baked beans at my grandmother's, said beans being spotted or speckled; and it seems to me they were more delicious and toothsome than any thing of the bean family I have tasted since. And this Best of All colored bean looks very much like those spotted beans of olden times that used to please us so much when we were children.

On looking the matter up, I find that, during a favorable fall, turnips may do quite well, even when sown in September. And, by the way, a few

days ago, when we were sowing crimson clover in the corn, with a little sprinkling of turnip seed among the clover, a visitor who was present clapped his hand on his thigh and declared:

"Oh dear me! why didn't I think to mix in just a little turnip seed when I sowed that crimson clover yesterday among the sweet corn?"

Now is the time to sow lettuce seed to be transferred later into the greenhouse. Sow the seed and push along the plants out in the open air, exactly as you would in the spring. Move them into the greenhouse just before they might receive injury outdoors.

The latter part of this month is the time to sow cabbage for cold-frame plants; and if you have got the hang of it you can have cold-frame onion-plants in the same way. We make it succeed to perfection. The onions will stand fully as much frost as the cabbage.

Our new Craig Seedling potato is still booming, and promises something almost unheard of. In answer to many inquiries in regard to the forthcoming prices of potatoes for fall shipment, I would reply that the matter is under consideration, and we shall be able to give reasonable rates, probably, in our next issue. If you want to send in your order we will guarantee that the rates all around will be a little lower, any way, than last year.

Scarlet Globe, Early Frame, and Rose winter radishes will all succeed if put into the ground now; and this is also the principal month for sowing spinach. For prices see our fall price list just out.

All orders for strawberry-plants are filled, and we are ready to put them up and send them off the day the order is received, excepting the Parker Earle and Edgar Queen.

Our vineless yam, or bunch sweet potato, is also promising a fine crop, even on our Medina clay. I tell you, a nice thrifty patch of them looks handsome, and the potatoes are said to be superior to the average sweet potato in the market—no vines to bother. The tops stand right up like an ordinary Irish potato.

To those who wish to try crimson or scarlet clover during the month of September, I may say we are prepared to send 1 lb. by mail for 20 cts.; 3 lbs. for 50 cts.; all postpaid. By freight or express we can furnish a peck for 90 cts.; $\frac{1}{2}$ bushel, \$1.75; bushel, \$3.40; two-bushel sack, \$6.50, package included. And, best of all, all the above is American home-grown seed—a lot that we recently ran across. The price is a little lower, as you will see, because it is getting to be a little late in northern localities; that is, it would be a little late in case we have a severe winter.

Seven-top turnip will grow all right if sown this month. Remember, it does not have a root, but only foliage for greens, and "posies for bees," early in the spring.

Last of all, now is the time to put out American Pearl onion-seeds. For prices see last issue.

KIND WORDS FROM OUR CUSTOMERS.

I don't see how I could get along without GLEANINGS. L. D. COFFMAN.

Clark, W. Va., June 17.

The Crane smoker I ordered arrived in good shape on the 28th, and I had an opportunity of trying it the following day. I found it equal to all it claims. Jefferson City, Mo., July 1. F. M. SELLERS.

The A. I. Root Co.:—Bees are doing well at present, but we are needing rain very much. I like GLEANINGS. It just suits me in every department. As long as you maintain the present standard of your journal you can count me as a subscriber.

Patronville, Ind., June 15, 1895. R. B. LARKIN.

The A. I. Root Co.:—Accept thanks for the generous number of sample copies you sent me for ten cents. I read them with some interest, some benefit, and yet I am left somewhat "rattled" over the various discussions on the different kinds of hives, frames, bees, etc. On one point I am certain: Men don't gather "flgs from thistles," and bees can't gather honey from fence-rails; they must have pasture, and that is rather scarce around here at present. D. MCCARTHY.

New Haven, Ind., Aug. 1, 1895.

QUEENS

By Return Mail.

Untested daughters of one of the best imported queen mothers I ever owned, mated to drones of the best of imported stock from a different source, 40c each. Also golden queens of the Doolittle strain same price. Safe arrival and satisfaction guaranteed. Please don't send stamps. No disease.

L. H. ROBEY, Worthington, W. Va.

Gove's INVALID-BED Attachment.

A priceless boon to the sick and their attendant. Positive in action. A child can operate it. Circular free. Patents pending.

Advantages of Bee-Escapes.

No sweat steals down the heated cheeks and aching back of the bee-keeper as the result of standing in the hot sun puffing, blowing, smoking, and brushing bees; no time is wasted in these disagreeable operations; and no stings received in resentment of such treatment; the honey is secured free from black or even the taint of smoke; the cappings are not injured by the gnawings of bees; and robbers stand no show whatever. If there are any broken burr-combs they are cleaned up by the bees inside the hive, before the honey is removed. **Leading Bee-keepers use the Porter Escape**, and say that without a trial it is impossible to realize the amount of vexatious, annoying, disagreeable work that it saves. The cost is only 20 cts. each, or \$2.25 per doz. As in the past, this escape is manufactured by the Porters, but The A. I. Root Co. has secured control of the sale for this country. Order of your dealer or of

Another Wonderful Cure.

Ever since my "calfhood" I had been in trouble, inherited a tendency to "breaking out," and a few attacks I have often been confined to the stable for weeks. Also troubled with a ringing sensation in my nose, and a feeling as if stuck with pitchforks by angry men. I was threatened with "Bologna treatment," but a friend recommended **Elasticity** as compounded by the Page Woven Wire Fence Co., Adrian, Mich. One dose worked a complete cure, and I can freely recommend it in all similar cases.

Yours truly, Durham Bull.

HONEY COLUMN.

CITY MARKETS.

DENVER.—*Honey.* Our market is being well filled up with new honey, especially comb. There seems to be very little demand for extracted. We have been receiving quite a number of shipments for which we have been getting 10¢/lb. Our trade requires a No. 1 white grade, suitable for putting in our cartons. Extracted, No. 1 white, in 60-lb. cans (2 in a case), 6¢. Beeswax, 25.

R. K. & J. C. FRISBEE,
Denver, Col.

Aug. 27.

NEW YORK.—*Honey.* New crop is arriving; and while receipts from N. Y. State are light, we are getting a large supply from California. Received two cars choice comb from there, and have several more to follow. Demand is rather limited as yet on account of the warm weather. We quote: Fancy white, 1-lb. sections, 15¢/lb.; fair white, 1-lb. sections, 12¢/lb. No demand as yet for buckwheat or dark honey. Extracted is plentiful, especially California and southern. We quote: California, 5¢/lb. cts. per lb.; white clover and basswood, 6¢/lb. cts. per lb.; southern, 45¢/55¢. per gallon. Beeswax firm, and in fair demand at 28¢/29¢. per lb.

HILDRETH BROS. & SEGELKEN,
120-122 W. Broadway, N. Y.

CINCINNATI.—*Honey.*—Demand is lively for new extracted and comb honey. Arrivals are fair, but insufficient for the demand. Comb honey brings 14¢/15 for choice white. Extracted, 4¢/7. Demand is good for beeswax at 20¢/25 for good to choice yellow.

CHAS. F. MUTH & SON,
Cincinnati, O.

Sept. 10.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7¢. Same, partly from cleome (tinted), 6¢. Samples, 8¢.

F. N. JOHNSON,
Box 137. Knoxville, Knox Co., Ill.

WANTED.—To exchange pure - bred short - horn cattle, either cows or bulls, for clover or basswood honey. If you want good cattle, write me for prices.

CALVIN LOVETT, Otsego, Mich.

Black and Hybrid Queens For Sale.

A dozen or more fine mismated Italian queens for sale at 25 cts. each. They are all young and prolific, and a good share of their bees are yellow.

MRS. THOS. STRAWBRIDGE, Ottawa, Kan.

Hybrids for 20 cts.; mismated for 30 cts.

C. G. FENN, Washington, Conn.

For Sale, 50 Colonies Italian Bees,

With fixtures and honey crop on, with a fine place, 8½ acres; land at a bargain. Address

L. WERNER, Edwardsville, Ill.

Closing-out Sale....

Warranted purely mated queens at 50 cts. each; ½ doz., \$2.75. Good queens of the five-banded strain of Italians. Tested queens, 65 cts. each; ½ doz., \$3.25. Sent by return mail.

W. A. Compton, Lynnville, Tenn.

IMPORTED QUEENS, \$3.25. Untested, 50 cts.

W. C. FRAZIER, Atlantic, Iowa.

NEW CHICAGO BRANCH.

We are pleased to announce that we have bought from Thos. G. Newman, of Chicago, his good will and stock of bee-keepers' supplies, and have opened rooms at 56 Fifth Avenue, in the Garden City Block, where a full stock of bee-keepers' supplies will be on sale. We have secured Geo. W. York, editor of the *American Bee Journal*, as manager. Mr. York has had several years' experience in the supply business, when he worked with Mr. Newman, before taking charge of the *Bee Journal*. He therefore brings to the work sufficient experience to enable him to conduct our business there with satisfaction to all who may prefer to deal in Chicago.

Mr. York finds that he can profitably spend time in this work besides editing the *Bee Journal*, and we consider ourselves fortunate in securing him as manager for the new branch—the first one to be started in our own name. The address of the Chicago branch will be The A. I. Root Co., Geo. W. York, Manager, 56 Fifth Ave. The transfer is being made as we go to press; and we hope to have within a month a full stock in the new rooms.

SEED POTATOES FOR FALL SHIPMENT.

At the present writing we are prepared to offer lower prices than for many years. For instance, choice selected Beauty of Hebrons, we can furnish for 15 cts. a peck, 40 cts. a bushel, or 75 cts. for a bag containing two bushels; or a whole barrel of 11 pecks for \$1.25.

Monroe Seedling, Early Ohio, Freeman, Early Puritan, Lee's Favorite, Rural New-Yorker, New Queen, Bun-pee's Early, and Sir William, 1 lb., postpaid by mail, 15 cts.; 3 lbs., 35 cts.; peck, by freight or express, 35 cts.; bushel, \$1.00; bag of 2 bushels, \$1.75; barrel of 11 pecks, \$2.50.

The New Queen* was raised by T. B. Terry, as, in fact, are all our Freemans, both first and second sizes. And, by the way, there has been some complaint that the Freemans do not grow large. Give us an order for extra-sized Freemans and we will show you that T. B. Terry grows large ones any way. The Sir William is the potato chosen by W. I. Chamberlain, of Hudson, O., beyond all others on his test-grounds, for the *Ohio Farmer*, and he has 36 acres of potatoes of different kinds this season. A full description of both these potatoes will be given in our next issue. If you want samples to see what they are like, order by mail at the prices given above. By the way, friends, it is a most excellent plan to have your seed potatoes selected in the fall, when the prices are low. In due time we shall have some valuable articles telling how almost any one can keep seed potatoes clear into next June or July, without sprouting or other trouble.

* Here is what Terry says in regard to the New Queen, etc.:

FREEMAN ROOT. We shall have 30 to 40 bushels of good medium New Queen, strictly pure, and no blight whatever. I got the seed from Maine last spring, at a cost of \$50. They are of fine eating quality, and there is no better potato that I know of for early, to get off in time I want. We tried them two or three times. They are ripe. They are of a fine quality, and productive, as the old Early Rose or Beauty of Hebron in their best days. I thought to advertise them, but should be glad to sell out to you to get rid of the worry. I will send you some to cook and try, they are so white and nice.

The quality of the Freeman is simply superb this year. I want to send you some to eat with sample of Queens. There is a flavor about it, if cooked just right, not equaled by any thing else.

T. B. TERRY.

Hudson, O., Aug. 28.

The new potato, Craig Seedling, single pound by mail, postpaid, 20 cts.; 3 lbs., postpaid, 50 cts.; half a peck, by freight or express, 50 cts.; peck, 90 cts.; half-bushel, \$1.50; bushel, \$2.50; 2-bushel bag, \$4.50; barrel of 11 pecks, \$6.00. Second size of any of the above, half the above prices; but, of course, this would not refer to potatoes by mail, because the postage is a large part of the expense. Extra-sized potatoes—that is, only the largest and fairest—one-half more than above prices.

By the way, will our readers who purchased Craig Seedling potatoes tell us on a postal card how much seed they bought, of whom, how much ground they planted it on, and, as soon as they are dug, what the yield is? Do not be in a hurry to dig them, for they will grow and keep growing until frost winds them up; that is, I have never seen any of them die down before the frost killed them; and I would suggest to you not to sell any at less prices than given above. Our yield is going to be something enormous. But every potato will be wanted, little and big.

STRAWBERRY-PLANTS.

If you want strawberry-plants to set out this fall, the quicker you order them the better, for they must make root enough to stand heaving out by the frost, or you will be very likely to lose them. Bear in mind the Timbrel is now for the first time the same price as all the rest in our list of seven choice kinds. Prices—15 cts. for 10 plants; 75 cts. per 100; \$6.00 per 1000. By mail, add 5 cts. for 10, 25 cts. for 100, for postage. For Canada, double the above prices.

CABBAGE-PLANTS.

Now is the time to sow the seed of Jersey Wakefield cabbage for cold-frame plants, to winter over. Cauliflower may be treated in the same way, but it is a little more difficult; the same with Grand Rapids lettuce-plants. Spinach sowed now on exceedingly rich ground, say almost one-half old well rotted manure, will do better than at any other season, for the spring market, and Chinese Rose winter raish will be pretty sure to make a market size before frost, if put on this same enriched soil. Basswood-trees had better not be sent out until October. In regard to bee-plants, I do not know of any of the clovers that can be safely sown so late as this in our locality, but seven-top turnips sown now will, however, do nicely for greens and for honey next spring. They are so exceedingly hardy that they grow more or less all winter, and are seldom or never injured by a freeze.

GARDENING FOR THE MIDDLE OF SEPTEMBER.

I suppose almost every one is rejoicing over the improved prospects since the recent rains. A few days ago Mrs. Root was down in our creek-bottom garden, and in a few minutes I picked her some nice large beautiful Jessie strawberries, a bunch of both red and black raspberries, and some pretty fair blackberries. The red raspberries are the Marlboro. All the fruit was killed in the spring, and the result was, they set again, and gave us the largest, finest, and most luscious red raspberries we ever saw, in the month of September. The very rich soil had something to do with their great size. In regard to the "luscious," I took other people's word for it, as you know I can not even taste them now.

We are now selling green shelled beans, bush lima, Best of All, York State Marrow—and as nice peas as we ever raised at any time of the year.

Beautiful cauliflower, nice celery, late Mammoth Sugar corn, cucumbers, Emerald Gem melons. And, by the way, I must not forget to mention a new watermelon sent us by J. Wittenmeyer, Emison, Knox Co., Ind., which he calls the Sweetheart. A couple of barrels which he sent us as samples proved to be ahead of any thing in the line of watermelons ever sampled at the Home of the Honey-bees. The red sugary part of the melons extends almost clear to the outside of the rind. We shall have it in our new price list for 1896.

American Pearl onion-sets reduced to \$1.25 per peck, \$4.50 per bu. Now is the time to plant them.

Potatoes.

Craig's Seedling, Everett's Early, and Freeman, at prices given by A. I. Root above. W. B. Collins, Blackwater, Cooper Co., Mo.

Queenless Colonies

purpose, and want them *right off*, send your order to me. I can and will fill them by *return mail*. My queens are nice, young *tested* queens, and I sell them at \$1.00 each or six for \$5.00. One queen and the Review for \$1.50. One queen and the book *Advanced Bee Culture*, for \$1.25. One queen, the Review, and the book for \$2.00.

will often be found at this season if they are looked for, and when found should be given a queen at once. If you find any such, or if you wish for queens for any purpose, send your order to me. I can and will fill them by *return mail*. My queens are nice, young *tested* queens, and I sell them at \$1.00 each or six for \$5.00. One queen and the Review for \$1.50. One queen and the book *Advanced Bee Culture*, for \$1.25. One queen, the Review, and the book for \$2.00.

W. Z. HUTCHINSON, Flint, Michigan.

THE TORONTO CONVENTION REPORT FREE!

A *Full Report* of the Proceedings of the North American convention held at Toronto, Canada, will appear in the *weekly American Bee Journal* immediately after the meeting, Sept. 4, 5, and 6. The first installment will be in the number for Sept. 19. If not now a subscriber, you can have that Report *free* by sending \$1.00 now for the *American Bee Journal* for 1896, as we will "throw in" the balance of the year 1895, beginning with Sept. 19, to new subscribers. Think of it! over 15 months (or nearly 70 numbers) of the old *American Bee Journal* for only \$1.00!

And, besides all that, each new subscriber will receive a free copy of the 160 page book, "Bees and Honey." Better send on your dollar at once, and join the procession. Mention this paper, please.

GEO. W. YORK & CO., 56 Fifth Avenue, Chicago, Ill.

Proof Beyond Doubt.

A customer, looking over my 400 hives in home apiary, said, "Where are your bees? Mine were flying all around thick this morning." I said, "Just stop; look down at any hive." He was amazed. They were just pouring in thick with their heavy loads. This proves two things—they can't be excelled as workers, and quiet.

I opened several hives. He had no veil; was in the apiary $\frac{1}{2}$ of an hour; was not bothered once. Try them. Untested guaranteed queens, 75c. Send for wholesale price list.

Wm. A. Selser,
Wyncote, Pa.

The Bottom is Out!

For the next 60 days we will sell warranted purely mated queens at 55 cents each; six, \$3.00; tested, 75 cts. each; six, \$4.00. All queens sent by return mail. Satisfaction guaranteed. Address

LEININGER BROS.,
Ft. Jennings, - Ohio,

World's Fair Medal

Awarded my *Foundation*. Send for *free samples*. Dealers, write for wholesale prices. Root's new *Polished Sections* and other goods at his prices. *Free* Illustrated Price List of every thing needed in the apiary. *Bees* Branch, Mich.

MARTINS eat bees, says W. Woodley, in *British Bee Journal*.

UNITING BEES will be more successful if you kill the condemned queens two or three days before uniting.

CRIMSON CLOVER is also called scarlet clover, German clover, German mammoth clover, and Italian clover. Its botanical name is *Trifolium incarnatum*.

THAT SCREW-EYE of F. A. Gemmel, for fastening number-tags on hives, is good—easier to use, and more secure. With nails some of my tags have been lost in hauling.

ABOUT THE TIME I'm writing this, bee-keepers are focusing toward Toronto. How I'd like to see them all! [So say all the members who couldn't go, I imagine.—Ed.]

SPEAKING on p. 670 of the very rare instances when queens sting folks, you might have added that, in rare instances, a virgin queen has been known to sting to death a worker. Seen 'em.

HONEY CLOVER and bee clover are among the common names of balsam clover, *melilotus ceruleus*. From the names one would think it ought to be a good honey-plant. But does it grow this side of Germany?

PARIS GREEN, according to C. L. Marlett, in *Insect Life*, is made in grains unnecessarily coarse merely for the sake of looks. It can be made fine at less expense, and will remain in suspension three times as long.

PUNIC BEES are no longer mentioned. Yet wherever any of that jet-black blood is left in my apiary I find good workers. But they're cross, and not fit to make comb honey. They make watery combs, and, oh the bee-glue!

MY VERY YELLOW BEES are very gentle, and, so far as I can judge, good workers. But I object to the opinion that they or any others are good *because* they are very yellow. [That's the point; but the reports—that is, the great

majority of them—show that they are not good workers or good at any thing else.—Ed.]

HONEY VINEGAR is perhaps not made as much as it should be. A writer in *British Bee Journal* says, "By using an extra quantity of honey one gets a splendid acid beverage that will compare favorably with raspberry vinegar."

IF A. I. ROOT gets everybody on a strictly meat diet, what in the world will he do with all his garden sass? [That's a conundrum that has come to me. We'll see him going into cattle-raising as his next hobby; so, look out.—Ed.]

THE HEDDON HIVE, says the *British Bee Journal*, "had a short run of prominence here for a short time, but soon fell into disuse among British bee-keepers." [But why? is a question a Yankee would ask. Will some English cousin please tell us?—Ed.]

THE AVERAGE YIELD of a good colony is set down, p. 670, as "anywhere from 5 lbs. to 75 lbs. of comb honey." You might lower the smaller number about 25 lbs. [That's true; but *then* it couldn't be called a "yield." I was talking about *yields*, don'tcher know?—Ed.]

"IN ENGLAND, where crimson clover is grown with some difficulty, it is said to winter-kill if sown on newly plowed land, but to pass the winter uninjured if merely harrowed in on stubble."—*Bulletin 125, Michigan Experiment Station*. That is, sow on hard rather than mellow ground.

CHORDIS STULL says the rule about drouth making tomatoes rot doesn't work in this locality, where many acres are raised. Drouth was worse this year than last, vines dying this year from drouth, but not one tomato rotted this year for ten last, until the recent rains. Since the rains they're rotting badly. [It works just the other way here.—Ed.]

SAY, ERNEST, tell us more about that paragraph, "Large Colonies for Honey," p. 673. Did you get any section honey from a colony in two eight-framers? [Now, you shouldn't ask such questions. That whole apiary was run for *extracted*; don't you remember my saying

so? Say, but if I had run for *comb*, I am afraid there wouldn't have been so much on those double-deckers. What more do you want me to tell?—ED.]

RAPE is a great honey-plant in Germany, and perhaps elsewhere, but is little known in this country. The *Stockman* thinks it is destined to become much better known here; and Prof. Thos. Shaw is "certain that it is to be a great factor in solving the problem of cheap-mutton production." "Am pasturing six sheep and ten lambs in fine form on an acre of land."

IF BEES STEAL eggs from other hives, W. Woodley asks in *British Bee Journal*, "why do colonies ever die out from queenlessness after breeding has commenced in the spring, and eggs can be had for the fetching from other hives?" [It was never claimed, if I am correct, that bees always steal eggs, but only that there was strong evidence that they have done so under pressure.—ED.]

I NEVER DREAMED that any one would understand that straw to which S. T. Fish & Co. refer on p. 669 as meaning they were not entitled to having consignments. It simply meant that honey was so scarce that prices must go up before consignments would pour in. The Honey Column for Sept. 1 justifies my anticipation. No quotations are lowered, and some have gone up a cent or two.

NUMBER-TAGS of manilla well-soaked in oil look very promising. They cost so much less than tin that we can try a set; then if they give out in too short a time we can turn to tin. But I earnestly entreat you not think of giving us figures less than $1\frac{3}{4}$ to 2 inches in height. After Mr. Winder has put 1-inch figures to a fair test he'll want to stretch them. [Yes, we'll have respect for the larger figures.—ED.]

MR. M. M. BALDRIDGE speaks almost complainingly of the cropping of sweet clover by stock on the wayside. Nothing pleases me better. For when the stock and its owners both find out the value of sweet clover as a forage-plant it will soon find a permanent lodgment in fields. And I'd rather see every plant on the roadside cut down; but I wish they would cut it before blooming. Then we get greater value in later blooming.

AUGUST 9, put in No. 20 bees with brood and queen-cells. August 26, found present a virgin queen with one wing torn away. Killed her and began distributing the bees and comb, when I found another virgin queen with whole wings, neither of the queens appearing very young. The latter queen began laying Sept. 3. Did each queen have a faction of adherents loyally protecting her, or how was it? [Are you *sure* the wing of the first queen was torn away? I should guess that she was "born" so. Still, it is not improbable that the wing could have been removed by the bees.—ED.]

SPACING-STICKS for keeping top-bars at fixed distances, who invented them? After they become well glued, and I try to use them, I feel an ardent desire to use one of them to whack the head of the man who got me to try them. [I may as well confess that I was the man who got the doctor to try them. Another chap put the idea in my head; and before I tried them I sent some of the sticks to the doctor, and this is the way he would use me. Well, I don't blame him; for, after I had tried them, I felt just like, like—kicking myself and the "other chap" too. No, sir; I want spacing-devices to be part and parcel of the frames themselves. They are a mistake when made detachable in the way of sticks or when a part of the hive-body itself.—ED.]

THE HOUSE-APIARY described on p. 662, if I understand it correctly, costs \$3.36 per colony, besides cost of hive. There ought to be a very big advantage to offset that. [That's true; but this figure covers winter protection—that is, saves packing-cases or more expensive double-walled hives; or toting bees in and out of cellars every fall and spring as you do. Again, it saves in economy of room; saves steps, as the hives are all close together, and saves disagreeable outdoor robbing. The house is a big advantage in the matter of extracting and in fall feeding. It can be locked; and bees, honey, and all be tolerably secure from petty thieves. Tools, such as smoker and the like, always under protection from the weather; and it makes no difference what the weather is, the apiarist can work right along. Last of all, the building may be used as a temporary storage for honey just taken off. The outdoor plan usually calls for a little building for tools, storage, and a general shop. The expense-item, if considered in the long run, is rather in favor of the house-apiary.—ED.]

THE HIVE QUESTION.

EXTRA LARGE HIVES NOT ALWAYS MOST PROFITABLE; LARGE AND SMALL BROOD-CHAMBERS COMPARED.

By B. Taylor.

Editor Gleanings:—After reading the five or six interesting articles in July 15th *GLEANINGS*, on large or small hives, I can not refrain from adding a final word. I have been making some careful observations directly in that line this season. I am now trying to earn a living by raising honey, and am very anxious to find and have the advantage of a hive that would give best results, and would at once use a large hive

if I could find the proof that such was best. Now, I have learned by experience that extra-large swarms are not always the most profitable. Such, as a rule, are the ones that give trouble by deserting their hives, after being hived, and that whether they are hived in large or small hives; and I also *know* that they do not always make the most surplus, even when they work contentedly; yet I like fairly large prime swarms; and as the large-hive brethren are always talking and writing about the advantage that their large hives give in sending out larger swarms, I concluded to try some careful experiments in that line. So last spring I put out some ten swarms in hives containing ten combs 13 inches long inside the frame, 6¼ inches deep, 80 inches in each comb, or 800 in the hive. As many more contained 1000 inches in the hive, while 25 contained 1600 inches each. All the hives contained colonies of nearly equal strength, but with a little advantage in favor of the large hives. All of these had abundant natural stores, and were treated in other respects as nearly alike as possible. The 1000-inch hives produced the first swarms, closely followed by the smallest ones. Some of the large hives swarmed reasonably early; and where they did, the swarms were in no case extra large, but in some cases *smaller* than those from the *smallest* hives.

I had said nothing to my son, who, in most cases, put the swarms into the catchers; but he very soon came to me and said that some of the very largest swarms were coming from the smallest hives. Two years ago I told in the *Review* how I had produced the second largest amount of comb honey I ever raised from a single colony (250 lbs.), all the bees of which were raised in one of those little 800-inch hives. That hive swarmed rather late in the season, but the queen did not follow. The swarm returned, and did not come out again, and this queen had been marked for destruction the previous fall on account of seeming inferiority that season.

The swarms I have mentioned as coming first came just as or a little before the white and al-sike clover bloomed here, and have made what white honey I shall get this year. Near the close of the clover season most of the large hives swarmed, and the swarms were very large—much larger than any from either large or small hives that swarmed early, and some of them cast second swarms of great size.

Now, friends, these large hives had made no section honey worth mentioning, previous to swarming—not nearly so much as the smaller ones; and need I point to the fact that these great swarms came *after* the battle for this year was over? and unless the fall differs from those of 1893 and 1894, they will prove worthless. If there is a good fall flow of nectar, which seems promising now, they may partly redeem themselves; but the swarms that have made

considerable white will share equally in the benefits of a fall flow.

I always read Mr. C. W. Dayton's articles with interest, whether I agree with him or not. Bro. Dayton is both a thinker and experimenter, and always has some demonstration to back his opinions. I am not surprised that he has come to the same conclusions in regard to hives, nearly, as myself. *He has been at work.*

I remember that, at the national meeting at Chicago, in 1893, a vote was taken, both for and against double brood-chambers. Some fifty votes were cast. Nine-tenths of them condemned such hives. Those who had tried such hives were then asked to stand up. Some four or five arose; the other forty or more had nothing but *prejudice* and lack of knowledge upon which to base an opinion. Thus we go blindly through life, condemning those who have *searched* for truth, and in religion and politics, honestly believing that things that are right are wrong, and that things that are wrong are right. Let us prove things by investigation, and hold fast to the things that prove true.

Forestville, Minn.

[Since the above was in type, Mr. Taylor has sent us the following by way of explanation of a few points.—Ed.]

Editor Gleanings:—I wrote you an article a day or two ago, on the effect that the large hives have on the size of swarms. There was one point I ought to have mentioned in that article; viz., the quality of brood-combs. I have eight hives of the Langstroth ten-frame size that I took of a friend last spring. An examination of them has led me to make that explanation. Now, as a part of my last article, these Langstroth hives contain nearly twice as many inches of brood-combs as my smallest hives mentioned in that article. The combs had been built on wide strips of foundation. The consequence was, some frames were filled nearly solid full with drone comb, and there is scarcely a frame but has some drone comb in it. The consequence is, my 800 inches of comb in the small hives has more worker comb than one of these big ten-frame hives. Let it be borne in mind that all the hives mentioned in the experiment were solid full of *worker* comb. I have fifty hives now in the apiary that have not enough drone comb in them all to fill a single frame. The combs were built on worker foundation, in frames with horizontal wires, so that all sagging was prevented, and all bee-spaces are not over ¼ in.; so there is no place for drone comb in them. I have examined hives in which I could not find a single drone-cell. This is the best drone-trap ever invented: *Raise no drones to trap.* I have heard it suggested that such colonies would not swarm; but it is all theory and no fact, like many cherished notions in all trades 25 years ago. In the afternoons the drones would fly from the hives, with a roar like

a waterfall; but now there is never heard that death-knell of *paying* honey crops in our beeyard, in such a year as this. The conditions existing in our apiary twenty years ago would render any surplus impossible. I shall get some surplus. So much for modern improvement.

Forestville, Minn., July 23. B. TAYLOR.

[Heretofore the testimony has seemed to show that there were more swarms with small than large hives, but your experience seems to be the other way. Has any one else had experience similar to Taylor's?—Ed.]

A TEN-FRAME HIVE AND A GOOD QUEEN.

I am becoming interested in the hive question, and will tell you the hive I want. It is the one that has the best queen in it, and it takes a ten-frame Simplicity hive to hold her with three T supers on top; but two are holding her this year. So far she has 46 sections finished to date, and I run 20 ten-frame simplicity hives of bees, and 37 eight-frame hives of bees this year. Out of the 20 ten-frame hives came 4 swarms; 37 eight-frame hives cast 27 swarms. That's how they did this year with me. What has become of G. M. Doolittle? Have him wake up and tell us all about what kind of hive to use.

H. W. VANKIRK.

Washington, Pa., July 23.

TEN-FRAMES AHEAD.

I should like to add my mite to help out the ten-frame hives. Let your arguments in GLEANINGS go on a while, and we shall find out that many have changed to the eight-frame hive against their own pocketbook. I have always been afraid to leave the ten-frames, so have kept half in each for five years. The tens are always ahead. I have this spring 40 colonies—20 eight and 20 ten-frames. Seventeen of the tens have ten frames below, and super with from 10 to 25 lbs. in, and only 5 eight-frames have the average 10 to 25 lbs., and are ready for supers. The rest have no supers on yet. I use half-depth extracting-supers at first. It is very cold here at present.

C. G. NEVIUS.

Chiles, Kan., May 23.

SHALL THE HIVE DISCUSSION CLOSE?

I have read with so much interest the articles on small vs. large hives that I am sorry to see the argument close. I am a bee-keeper on only a small scale, but I want to have the proper size, as I expect to engage more extensively in the bee business in the future. I believe the location is the greatest problem to solve, so that we can arrange the size according to it. We know positively that, the more space we have in the brood-chamber, the more bees it will require to keep it warm; the more bees you have, the more honey it takes to carry them through the winter; hence you have it in a nutshell.

And now, Bro. Root, if you will allow me I

should like to give you my experience with three hives during this summer, and I will try the same thing again another season if I live. It is this: I took the three hives and placed them side by side, and had the same kind of bees in each hive. One hive contained nine frames, one eight, and the other six. The eight and six are thick top-bars, and the nine are $\frac{1}{2}$ -inch. I have not 1 lb. of surplus from the nine; got 10 lbs. from the eight; and 20 lbs. from the six; and to-day the six has 10 or 12 lbs. on, while the others have none; so, now, which hive can I chose for business?

Blacklick, O., Aug. 15. D. N. RITCHEY.

A FEW FACTS AND FIGURES IN FAVOR OF THE TEN-FRAME HIVE.

GLEANINGS is a welcome visitor. I think you might just as well give up the discussion, because the location and honey-flows make all the difference of opinion. I started with ten-frame hives several years ago; then when they made the strong claims for the eight-frame hives, I put one-half in each, eight and ten frames. With my location as to honey-flows, my ten-frames store 2 lbs. to 1. The eight-frame hives and the eight have done all the swarming until this year, when the swarms all came from the ten-frame hives. The cause was, the ten-frames stored enough honey from fruit-blooms to carry them through to the next honey-flow, while the eight-frames nearly starved. These are about the amounts that they have stored this year so far:

18 colonies, 8-frames, 230 lbs. comb. 300 lbs. ext.
20 colonies, 10-frames, 400 lbs. comb. 600 lbs. ext.
Two best 10-frames stored 100 lbs. each.
Two best 8-frames stored 30 lbs. each.

We always have a fall flow commencing the 20th of August. The prospects are the best in four years.

C. G. & W. V. NEVIUS.

Chiles, Kan., July 22.

[This is the first letter we have received intimating that the hive discussion had better be discontinued; but if we can get a few facts such as are here given, it ought to go on a little further yet. To have stopped it three months ago would have left us but little wiser than when we first started out; but now we have learned what a bearing locality has in the matter; that there are more using ten-frame Langstroth hives and deeper hives than we supposed. But if even a few vote to have this discussion discontinued we will do it.—Ed.]

RAMBLE 140.

AT M'CUBBIN'S.

By *Rambler*.

On the 26th of November Mr. McCubbin devoted a good share of the day to driving the Rambler out among the bee-keepers. Our first call was upon Mr. C. M. Davis, who had an apiary of 125 colonies upon the home ranch, and another apiary 60 miles away, over on the

MR. J. C. MCCUBBIN GRADING HIS COMB HONEY.

West Side. He was engaged in getting his honey ready for market.

Mr. R. E. Zimmerman was another prosperous bee-man, and very patriotic. He had just been elected to serve his country as constable, and did not seem to wear any larger hat than we common people. He was more successful as a candidate than our friend McCubbin. The latter was also patriotic, and ran for office; but owing to the fact that he belonged to the right party he was not elected.

Mr. Zimmerman is the happy possessor of 225 colonies of bees, or was at the above date. His apiary showed something of the wear and tear of the late political strife; and, the soil being of a very productive nature, the weeds had gotten the start of him; but in spite of politics, a dry season, and healthy weeds, his best apiary of 120 colonies had averaged 60 lbs. of comb honey to the colony, and he was busy at work in a cheese-cloth honey-house getting it ready for market.

Mr. McCubbin's apiary of 143 colonies was nicely located upon what I should call very poor soil. Even weeds would not grow there. It is, however, possible that his political sentiments of prohibition went so far as to interfere with the personal liberty of the growth of the weeds. If so, I have no doubt the weeds loudly protested, as all weeds do in the moral world when an effort is made to root them out. I mentioned the fact that Mr. McC. had several tons of honey in his residence in town, and here in his honey-house at the apiary were several tons more which had just been taken from the hives, and was ready to be graded. I secured a fine photograph of our friend and his honey.

Mr. McCubbin is something of a genius, and believes in short cuts to save labor. The photo shows his portable shelves and his method of using them. The shelf is constructed by nailing together at the edges two boards, six or eight feet in length, twelve inches wide, then nailing in square end-pieces as shown. In use, these shelves tier up; the honey is brought from the hives, taken from the supers, and placed upon a shelf. When this is filled, an empty shelf is tiered upon it, and so on until a large amount of honey is upon the shelves. Two smaller adjustable shelves or brackets are attached, and moved as the operator requires, while grading and packing.

Eight sections of comb are placed together upon the little shelf. In Mr. McC.'s hand is shown a small V-shaped strip. One of these strips is nailed upon each corner of the sections. The eight sections thus held compactly together in one box, as it were, are then packed into the crate shown upon the upper shelf, holding 48 sections.

The adjustable bracket upon the middle shelf is a handy receptacle for nails and strips.

Mr. McC. thinks he can work much faster this way than to crate from the supers as they are taken from the hive.

The section used by our friend is $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$, and holds a trifle over 12 oz. Many bee-keepers use this size section about Selma. The preference is gaining ground for a section that will hold a full pound. From 140 colonies Mr. McC. secured during the last bad year 6300 lbs. of comb honey and 1500 lbs. of extracted.

The increase in Central California comes early; then there is a dearth of honey in May, followed by a flow of nectar all through June, July, and August. The early alfalfa bloom yields but a small amount of honey as compared with that secured from the later bloom; and the early and late maturing of blossoms lengthens the honey season. Here it is a period of sweetness long drawn out.

Apiary work commences here in March, as it does further south; but instead of ending in July, as it generally does in the southern counties, the bee-keeper is kept quite busy clear up to December. The few intervening months are profitably spent in preparing for the coming season. Central California bee-keeping needs no side issues, for there is enough to it to make it an all-the-year-round business. In the little town of Selma there are seven bee-keepers. Their apiaries are located at various points all the way from one mile to ten from town; and several progressive men like Mr. McCubbin devote their entire time to bee-keeping. One of these progressives is Mr. O. W. Stearns. He resides in a pleasant home in the suburbs. His apiary of 390 colonies is out of town; but he has a few colonies near the residence, just to hum around and keep him company. Mr. S. manages on economical principles, making hives of gasoline and oil cases; and while he practices economy outside the house, a worthy helpmeet manages things in the house and shop, and attends to many little details that would escape the attention of the men; for instance, Mrs. S. saved 14 lbs. of nice beeswax which she made from scraping sections and frames that had been thrown aside as worthless. From the amount of beeswax I have seen wasting in many California apiaries it would be an excellent idea for many more ladies to take a hand, especially in the wax management of bees.

Mr. Stearns said that, from 30 colonies, spring count, he increased to 71, and obtained 5000 lbs. of comb honey. To further demonstrate what his bees were doing at that date, Nov. 27, Mr. S. opened some of his coal-oil-case hives and showed us combs that had been drawn out, and well filled with honey, but not sealed. Holding up a new comb, "This," said he, "has been drawn from foundation, and filled, as you see it, since election day. The product was grape honey. As the reader is probably aware,

all of this country around Selma and its neighboring city of Fresno, is planted largely to grapes, and the product of the vineyards is, to a great extent, raisins. After the harvesting of the main crop, there is more or less of a fall crop that nearly all goes to waste. Birds and insects live upon them, and the bees bring in much of the juice; and, from the sample of comb shown, it answers for drawing out foundation, and bees will winter well upon it, for I have in mind parties who pressed out the juice and fed it to their bees in Southern California with success. The product from the Stearns hive would not be pronounced good honey, for it had not undergone very much change. It was grape juice still, and had a distinctive raisin taste.

Although our friends had nice comb honey, all they were offered by dealers was 8 cts. per lb., and the most of it was sold at that price. They were, furthermore, suffering from a rank injustice in relation to tare on honey-cases. Upon a case weighing 4 lbs. a tare of 7 lbs. was taken; upon a 6-lb. case, 9 lbs. tare — a clear steal of 3 lbs. on every case. Individual action in shipping was hampered by the railroads charging excessive freight rates upon less than car lots; and as but few bee-keepers produce carloads of comb honey they have to submit to the extortion. Coöperation, it seems, would help the bee-keepers of Central California, as well as the bee-keepers of the whole country. Let's have coöperation.

Mr. Wilder and I concluded that we should like to enjoy the hospitalities of Bros. McCubbin, Zimmerman, Stearns, and a host of other bee-men, for several days; but the clouds, and a sprinkle of rain, admonished us again to be on the road, and we left our friends, feeling that Central California, though not written up to a great extent, is a honey-producing location that will attract more attention as the area of alfalfa is increased. We also desired to turn aside from our route and look up the honey resources of Kings Co., and around about Tulare Lake. In Lemore, Kings Co., resides Mr. J. F. Flory, a gentleman not unknown to the readers of GLEANINGS, and an extensive honey-producer, not only in Kings Co., but also the West Side. We could only look that way while our ponies were speeding toward Bakersfield.

KEEPING TOPS OF SECTIONS CLEAN.

A BEE-SPACE BETTER THAN QUILTS OR SHEETS,
AND WHY.

By Dr. C. C. Miller.

A correspondent thinks some one should invent a way to keep the tops of sections clean. I don't feel very sanguine in that direction, as to any great improvement over the present. There are two ways in practice. One is, to leave the

tops entirely uncovered; and the other, have them covered. If left uncovered, there is nothing to hinder the bees from putting on all the propolis they like. With a cover of enameled cloth or any other cloth, the bees push glue into the crevices, and gradually raise the cloth until the glue is a quarter of an inch thick and all over the top. A rigid cover of wood is not so bad; but I never saw any thing of this kind but that the bees could squeeze in a line of glue along the edges. Perhaps it is because it is impossible to have a perfectly close fit with a rigid covering.

The only way I can think of to have something fit down close enough would be to have a cloth cover; then over this lay a bag of sand, so that the weight of the sand might press down at every point. It is possible, however, that it might take something like a wagonload of sand to press down hard enough so the bees could squeeze in no glue.

On the whole I have been best satisfied to leave the tops of the sections free for the bees to manage as they like. Watch closely and see how the bees manage a super in which the sections are left uncovered, and one at the same time in which a slat covers them. In the early part of the season propolis is not so plentiful as later, and bees don't seem called upon to use it as a varnish, except to glue up cracks and crevices. They will crowd in glue over the edges of the covered sections, and leave the uncovered sections clean. Later on, after the white-honey harvest is over, there seems to be a surplus of propolis, and it is smeared everywhere, even on flat surfaces. At this time the uncovered sections get the worst of it, being painted all over, while the covered ones are clean, all but the edges.

As we can generally manage to get sections off before the glueiest time comes, I think less glue will be found on the sections left entirely uncovered, and we must be satisfied to scrape off all we find.

NEW THINGS.

"Why is it, doctor, that people seem always ready to down a new thing?" writes a friend. The first part of the answer to that is, they're not. What bee-keeper is there who hasn't a lot of traps stored away somewhere, or lying kicking around, showing the many new things that were received with favor, only to be found wanting when tried? Witness the favor with which the Chapman honey-plant and other new honey-plants were received. But who has a field of them now? All of which goes to show that, as a rule, people are not down on new things to an intolerable degree.

As experience tells us that the majority of new things will not prove desirable, it is only right that, when a new thing comes up, we should want to know all we can about it. Foundation with a veneer base is instanced.

You think it looks nice, and you regard it with great favor. After you have fully tried it, your word will be worth more, whether your decision is adverse or favorable. And until you have tried it you want all the light you can get. I've tried something a little like it, foundation with a base of paper or tin foil. I'm pretty sure, you'd want to know how that succeeded, and those who have tried any thing of that kind, and failed with it, ought hardly to be censured for telling of the failure.

But you say, "There are new things that are good; why not give a level-headed judgment always, and tell us in advance what things are worthless and what are worth a trial?" Dear me! who knows enough?

Marengo, Ill.

[Yes, it is true that most new things are not what they seem to be at first. Another instance is the Langdon non-swarmers device. On paper it looked like a "big thing," but in the practice of bee-keepers generally it did not prove to be such. Reversing of brood-frames and hives was another new fad that rose and died again. Contraction of the brood nest had its day, and now is gone largely into disuse, and so I might go on and name a lot of others. But bee-escapes, among the more modern "new things," especially the Porter, stands out as a brilliant exception.

Your friend refers to wood-base foundation as something new. Why, that is, I was about to say, one of the very old "new things," if I may use such language. It had its day years ago. Now the question is, shall it have another? The fixed-frames idea was an old fad, and came near being left out the catalog of modern appliances altogether. But experience has shown that it was condemned too hastily, and that because of their real merit they were bound to come up again and stay up. I hardly think this experience will be duplicated in the case of wood-base foundation.—ED.]

ITALIAN OR CRIMSON CLOVER.

TRIFOLIUM INCARNATUM, ETC.: AN OLD HONEY-PLANT IN ENGLAND.

By Samuel Simmins.

Editor Gleanings:—I have been interested in your experimental trials with this clover, and notice your request in GLEANINGS for August 1. You appear to consider it, or its honey-yielding qualities, as something only recently discovered. You will find it mentioned in "Modern Bee Farm," 1887 edition, and on page 55 in the later issue, of which I had the pleasure of forwarding you a copy. The plant has been known to and appreciated by bee-keepers here for many years. Around our large towns it is sown in extensive areas, being cut for green food and sold to owners of town stables, as well as greatly valued for home use. Bees simply roar on it, and store heavily for the few days it is in flower. That time is short, as it is usually cut before reaching full bloom. If allowed to stand for seed, however, the bees have access to it for from six to eight weeks at a stretch, and in good weather there is a continuous hum over

the field. The honey is light in color, and of fair flavor. There is also a *white* variety, but I am not aware that it is as useful for honey. Like most clovers, the seed can be sown to make a profitable crop only in the autumn for the following year's use.

I have sown this summer (July) buckwheat, trifolium, and melilot clover on the same piece of five acres. The buckwheat has come in bloom within one month from sowing. The mixed clovers are coming up nicely, so that for hay the crimson clover will be cut in ordinary course early next June, with a tender growth of melilot not in flower. Alone, the crimson clover makes poor hay, or, at least, it lacks scent, which the melilot supplies, and that one of the most fragrant kind. By cutting at that date, the flowering sweet clover to follow does not become so coarse as otherwise would be the case, and therefore is of more use as hay.

After once cutting, the scarlet clover is of no further value, though a few heads may again appear. Another piece of ground I shall have clear next spring, I propose to treat in a similar manner, except that in March, or earlier, mustard will be sown to come into flower from the middle of April, to be plowed in just as the final blooming is over. Buckwheat put in in June, harrowed and rolled, waiting for a wet season, any time up to September, before sowing the mixed clovers, as before; with no harrowing or rolling, as the buckwheat will be up and in flower.

It should never be forgotten that all clovers germinate best—in fact, *only perfectly*—when scattered on the very surface of the ground; therefore wait for a wet time if possible before sowing, and in three days the ground will be smothered with the new-born plants. Of course, the ground is to be got down fine and firm in the first place; and in dry weather, with no other crop up, it may be rolled after seeding, to advantage; but *never* rake or harrow *after* sowing clovers of any kind. Many a farmer has lost a crop—and a season—through sowing fine seeds previous to harrowing, and before rolling at all, thus setting it too deep for germination. Never omit to do both some time before; roll again after sowing if dry, but do neither after if a wet season can be waited for. Above all, never omit to roll down as hard as possible the following spring, as soon as the frosts are over, or the plants may fail to root properly again after the usual loosening of the soil—the result of the freezing.

Apart from its duration if left for seed, a succession of bloom may be had by cutting a part of the crop of trifolium *before* flowering at all, when, of course, that portion will come forward again, to bloom freely after that left standing has declined.

You may naturally ask, "Can not a succession be had by sowing at different times? or

will not the white and red varieties bloom at different dates?" So far I can give no satisfactory information on this point. Both appear to bloom at the same season. The plant must be started the year (autumn) before; and, whether sown earlier or later, the time for blooming is at the same period.

By far the best way is to work for a succession, as I have already shown, with different plants, which are all at their best in their own respective seasons, plowing under the last crop of melilot as the bloom fails.

In the ordinary way, the farmer sows over wheat, oats, etc., after cutting and carrying those crops (August to September), without cultivating, and therefore, of course, on pretty solid ground, and very little is needed besides rolling the following spring. A thin crop of trifolium is seldom seen. My directions, however, refer to cultivation for bees and forage. The buckwheat, of course, is always a valuable crop for its seed.

Seaford, England.

THE WEIGHT OF BEES, LOADED AND EMPTY.

THE MOST ACCURATE FIGURES YET GIVEN.

By Prof. B. F. Koons.

Friend Root:—Some two years ago, in a leisure hour I went to my apiary and captured one outgoing bee from each hive and subjected them to the fumes of cyanide of potassium for a few moments to render them inactive, and then weighed each bee upon our chemical balances—a pair of scales so delicately adjusted that it is an easy matter to weigh the one-millionth part of a pound or the one-thousandth part of a bee. From the weight of each separate bee it was a very simple problem in arithmetic to compute the number of bees in a pound. The results showed that mine, which perhaps are a fair average in size and weight, ran from 4141 to 5669 in a pound. These results you published in *GLEANINGS*, and there expressed a wish that I would also determine the amount of honey carried by a homing bee. In my research for the weight of bees I took those just leaving the hive, which naturally would represent the normal weight, having no extra honey or pollen on board.

During the present summer, when the bees were very active, I have undertaken to carry out your request as to the amount of honey carried by a bee. My method was this: From the chemical laboratory I secured a couple of delicate glass flasks with corks, marking them A and B. Each was very carefully weighed, and the weight recorded. I then went to a hive, and, with the aid of a pair of delicate pliers, or plucers, I captured a number of incoming bees and dropped them into flask A. I then secured about an equal number of outgoing bees in flask

B. These were then taken to the laboratory immediately, and each flask again weighed, after which the bees were carefully counted and released. This operation was repeated quite a number of times, not on the same day, but as opportunity offered, and when the bees were bringing in an abundance of honey. I captured from 20 to 45 bees for each flask at each trip, aiming to have, as nearly as might be, the same number in each flask on any particular trip. I always weighed the flasks before starting out, lest some little bit of soil or stain, or even moisture on the glass, would render the results less accurate; I also always allowed any moisture condensed upon the inside of the flasks, while the bees were confined, to evaporate before weighing for another trip. I then treated my results as follows: From the weight of flask and bees I deducted the weight of the flask; the remainder I divided by the number of bees confined on that trip. This gave me the average weight of the bees captured at that time. The average weight of the bees in flask A, or loaded bees, was always greater, as it should be, than the average weight of the bees in flask B, or unloaded bees. The difference between these two weights gave me the average amount of honey carried by that lot of bees.

Mine are Italian and hybrid bees, but I made no attempt to determine the difference in the amount carried by the different swarms or breeds. I kept no record of the swarms, except that I guarded against going to the same hive for a second lot of bees. A considerable difference does appear, but probably that arises in part from the abundance or scarcity of the honey on that particular day on which the colony was visited. My aim was to secure reliable results, as nearly as possible, representing the average amount of honey carried by bees.

The following is the result of weighing several hundred each, of the returning and outgoing bees. The smallest number of bees necessary to carry one pound of honey, as shown by my results, is 10,154; or, in other words, one bee can carry the $\frac{1}{10154}$ (one ten thousand one hundred and fifty-fourth) part of a pound of honey; and the largest number, as shown by the results, required to carry a pound is 45,642; and the average of all the sets weighed is 20,167. Perhaps, then, it is approximately correct to say that the average load of a bee is $\frac{1}{20167}$ (one twenty-thousandth) of a pound; or, in other words, if a colony has 20,000 bees in it, and each makes one trip a day, they will add one pound to their stores. Of course, not all the bees in a colony leave the hive, the nurses remaining at home, hence necessitating more trips of those which do "go a-field."

I also repeated my observations of two years ago on the weight of bees, and found that my numbers ran from 3680 to 5495 in a pound, and the average about 4800, the same as in my for-

mer test. I likewise secured the following on the weight of drones: Of a dozen or more weighed, the largest would require 1808 to make a pound, and the smallest 2122, or an average of about 2000 drones in a pound, over against nearly 5000 workers.

Bees have been doing reasonably well here in Connecticut this year. I keep my apiary reduced to 12 colonies, and from these I have secured 450 lbs. already, and shall perhaps have 150 more at the end of the season, and an abundance of stores for the winter.

The excessive drouth of 1894, and this year in June and early July, almost completely cut off the supply of white clover; but chestnut, sumac, buckwheat, and goldenrod, have yielded well. Basswood is too scarce in this State, particularly in the eastern half, to be counted among our honey-producing plants.

Agricultural College, Storrs, Ct., Sept. 3.

[I consider this the best article we have ever received on this subject—the more so because it comes from a practical man of science, and president of one of our leading agricultural colleges. I have marked this article for insertion in the 72d thousand (next edition) of our *A B C of Bee Culture*.

In a nutshell, and speaking in round numbers, we may say that it takes 4500 bees to make a pound; and that, while 10,000 bees may carry a pound of nectar, twice that number, or 20,000, is probably more nearly the average. During basswood bloom, the first figure should be considered as the nearer correct one because the bees drop down at the entrance; and from almost all other sources of nectar the twenty-thousand mark is the one to accept.

Let us now look at these interesting figures in another way: A bee *can* carry half its weight in nectar; and perhaps, under certain circumstances, a trifle more; but, generally speaking, one-fourth its weight is the amount. A single strong colony has been known to bring in a trifling over 20 lbs. of nectar from basswood in one day;* but usually four or five pounds is considered a *remarkably big* day's work. If we figure that there were, say, in the first instance (20 lbs. per day), 8 lbs. of bees, there would be 36,000 bees. If 20,000 of these were field-bees, (estimating 10,000 necessary to carry a single pound of basswood nectar), those bees must have made forty trips. On the same basis of calculation, a colony of equal strength that brought in 5 lbs. would make one-fourth as many trips, or an even ten. This would leave for each trip one hour for ten hours; or, in the case of 20 lbs. a day, twenty minutes.

There, perhaps I had better not carry this out further, or I may get into a tangle.—ED.]

THE RULE OF QUEENS AND AFTER-SWARMS.

CLOVER AND BASSWOOD NOT YIELDING HONEY.

By W. S. Foltz.

Dr. C. C. Miller:—In *Stray Straws* in July 1st GLEANINGS you ask, "If instinct impels so many queens to leave with after-swarms, what

holds any in the hive? or will all leave if out of the cell?" Did you ever examine a hive that had cast an after-swarm containing several queens, to see if any were left in the hive? and if so, how did you always find them? In my limited experience I have examined several such, and always found one or more queens, either in the cell or running over the combs. I have never known a hive to swarm out entirely queenless—have you?

In another *Straw* you say that you have known clover to yield honey; but it was not this year nor last. Will you please tell us how long it has been since you knew white clover to yield honey? Here it has been about ten years since we have had any clover honey. The editor wanted to know why you didn't move over into Wisconsin, where there are basswoods. We have basswood here, but don't get any honey from it oftener than about once in five years. Last year it bloomed, but the bees did not work on it, although there was no honey to be had from any other source while it was in bloom. This year there is no basswood bloom, and our bees are starving on raspberry juice, and practically destroying what little crop the frost left. You might as well let your bees starve for want of clover honey as to move them and have them starve for want of basswood honey. If there is no change in the production of honey here it will not be more than three years before there will be no bees in the country. Farmers have all let theirs die, and the few experts that have been feeding have got tired of an outlay that brings no income, and most of them will let what few bees they have starve the coming winter, if they do not gather enough fall honey to feed them through.

I aim to keep about thirty stands of bees, that being as many as I can attend to besides other work. Four years ago I purchased 2000 sections, and have not bought any since; and from present indications I shall have enough for ten years to come. Three years ago I had 35 stands of bees. They have dwindled down to 26, two having starved this summer. I have not had a swarm this season nor last. We don't have to experiment here to keep our bees from swarming. They have no desire to swarm. I wish they had. May be some of those fellows who are experimenting to prevent swarming would like to get a strain of bees that don't swarm. If so, we have them. They won't fertilize fruit-bloom either. I have tried them for more than 20 years, and they are "no good" for that. If some one has bees that swarm too much, and he can warrant them to fertilize fruit-bloom, I'd like to trade.

Muscatine, Ia., July 8.

[Dr. Miller replies:]

I think the rule is, that more than one queen is left in the hive after an after-swarm, but I don't know that the rule is invariable. I for-

*We had one colony that brought in over 43 lbs. in three days; and Doolittle 66 lbs. in the same time from basswood.

merly thought that no set of bees would be so idiotic as to let their last queen go out with a swarm; but I think I have read quite recently of such a case in one of the foreign journals. We know very well that an after-swarm often contains a number of queens. If four or five young queens come out with the swarm, or even if more than one issues, is a third not as likely to issue as a second, and so on for any number? And yet I think it is very rare that all the young queens leave the hive. Possibly close observation would show that in such cases all the free queens do actually leave the hive, leaving only such as are yet in their cells; and if all happen to be out of their cells, queenless results.

As to the yield of white clover here, the last to amount to any thing was in 1893, although both last year and this year I suppose a very little white-clover honey was gathered. But it was only a fractional part of what the bees required for their own use. The whole matter doesn't look very encouraging; but here's the tune I whistle to keep up my courage: No one knows any reason why we do not have the same yields as in former years. The whole matter seems to be in obscurity; and so long as we know of no reason for the lack of harvests, is it not reasonable to suppose that next year may happen to bring a big yield? It doesn't cost much to whistle that tune, and it makes one feel more comfortable. C. C. MILER.

Marengo, Ill.

HON. GEO. E. HILTON

AS A BEE-KEEPER LEGISLATOR; HIS CAREER
IN POLITICS.

[I am always glad to hear of the election of a bee-keeper (honest ones I mean) to a public office, be he a Republican or Democrat or what; but it gave me a peculiar pleasure when I learned that my friend Mr. Hilton had been chosen by the good people of his district to represent them in the Michigan State Legislature. "For," I said, "he is not only a good bee-keeper, but an earnest Christian gentleman, loved by all who know him. His influence will be for good."

Some years ago we gave a brief biographical sketch of him as a bee-keeper, for then he had not come before the public as a State servant. I have obtained a sketch of his political career that I take a real pleasure in submitting to our readers, because it is something that any one may well be proud of — not so much for its accomplishment of all things attempted as for the earnest *purpose* in the cause of right and justice underlying it all.—ED.]

His political career, outside of his township and village, was rather a surprise to him. In the fall of 1892 there seemed to be no candidate in his district for Representative in the State Legislature. His party had not elected a full county ticket in twelve years. The county committee were casting about for some one to lead the ticket, and the chairman suggested Mr. H. as one who had always been a true Republican, and did not have an enemy in

the county. The committee at once decided that he was the man if he would run. He was waited upon to see if they could use his name. At first he told them no, as he did not feel competent to fill so important a position if elected; but he said he would counsel with his wife, and report soon. She urged that he was competent, and ought to run if the party demanded it, though defeat was probable. That settled it, and he was subsequently nominated by acclamation. His opponent was nominated upon two tickets; but Mr. H. had a plurality of 425, and the entire ticket was elected.

The Speaker of the House, learning of his interest in behalf of good roads, made him chairman of the Roads and Bridge Committee, and in this capacity Mr. H. succeeded in passing the Good-Roads Bill, known as the "County System." Several counties have adopted it, and it is a success. Judge Hatch, of Bay City, wrote him as follows: "In ten years half the counties in the State will adopt it, and in twenty years Michigan will be a State of good roads.

HON. GEO. E. HILTON.

He was also interested in a bill tending toward reclaiming the semi-barren lands that Ernest saw in going from Flint to Manistee. There is no doubt these lands may be made fertile. The members from the lower portion of the State "stood in their own light," and the bill failed to pass, by five votes.

The other matters of legislation two years ago were of a local character that pleased his constituency so well that last fall they concluded to send him back, and he was again nominated by acclamation. The enemy said he should not go back, and succeeded in nominating the supervisor of his own township on their tickets, and yet his ticket in the first column looked decidedly lonely. But the harder the task, the harder one fights; and the result was a plurality of 923, and again every man on the ticket was elected.

He was, for his second term, given the important chairmanship of Committee on Railroads. In this capacity he has seemed to be able to please both

the railroads and the people. The Commissioner of Railroads, Lansing, Mich., at the close of the session, among other things said of Mr. Hilton that it had not been his lot to be associated with a man who had acted so impartially.

Among the numerous bills that Mr. H. was interested in, perhaps none received more attention than the one providing for a normal school in Northern Michigan; but in this matter we will let others speak:

The speech of Mt. Hilton, who pleaded earnestly for the farmers, pioneers, and home-makers in this comparatively new country, was most effective, and every representative listened and was touched. This section being new, and very remote from all the educational institutions of the State, the home-makers were unable to give their children the advantages so necessary to prosperity and happiness, because they are unwilling to be separated so long and so far, and because their means are limited, and must be wholly used in preparing the home. The impression made by Mr. Hilton was complete.—*Northwestern Tribune*, Mr. Pleasant, Mich.

Ed. Indicator:—Being present when the Central Michigan Normal-school bill passed the House, I heard the speeches made for and against it; and in justice to your Representative, Hon. Geo. E. Hilton, I want to say to your readers, through your paper, that, of all the speeches made (and there were seven), that of Mr. Hilton's was pronounced by all who heard them, to be the ablest in argument, best in delivery, and most convincing in result. Mr. Hilton plead earnestly for schools and education generally, and especially for Central and Northern Michigan—these newer counties where the young do not have the opportunities offered that the older counties are provided with. It was a warm fight, and a grand victory for the partially settled counties north of the capital, and Mr. Hilton threw himself into the cause and made a fine speech. It was in support of Senator Shaw's bill; and thus Newaygo County has the honor of furnishing two champions for the noblest work of all—the education of the young. LISTENER, in *Fremont Indicator*.

Mt. Pleasant, Mich., June 6.

During the last session of the Michigan Legislature there was a bill introduced by a member who had had a terrible experience as the result of bees being kept too near the highway. He and his friends were badly stung, and a span of horses he said he would not have taken \$300 for were stung to death. There seemed to be other members who had been stung, or knew of others who had been stung. When Mr. Hilton saw that the bill was going to pass, thus preventing the keeping of bees within 90 feet of the highway, he told the members that it would lead to endless litigation and family quarrels, and debar any one, owning a lot not to exceed four rods square, from keeping bees. He introduced an amendment so that it should read "from the center of the highway." The amendment was, however, defeated, and the original bill passed, and is now a law.

There was another bill introduced, making it a misdemeanor not to spray fruit-trees for the purpose of killing the enemies of fruit. This came from a horticulturist, and was a good bill for the orchardist. Mr. Hilton explained that it was worse than useless to spray while trees were in bloom, and succeeded in amending the bill, making the same penalty apply if trees were sprayed *while* they were in full bloom. The orchardist, knowing the bee to be his best friend, is pleased with the bill, which was passed as amended, and is now a law.

Last winter at Detroit he was elected a delegate from his district to attend the National Convention of Republican League Clubs, held at Cleveland June 19, 20, and 21.

[When I asked for a good photo of Mr. Hilton, the latter, in sending his own, sent along a couple of others that were, I thought, too good to be confined to the narrow confines of my own album, and I therefore asked friend H. if I might use them for the pages of GLEANINGS. To this he kindly consented. While our Michigan friend may or may not have a pardonable pride in his career as a bee-keeper and legislator, he *can't help* feeling a fatherly pride in those children.

There is one more thing I must say; and that is, in reference to railroads. We are too apt to feel that they (or, rather, their management) are only selfish and grasping. Mr. Hilton, who has had abundant opportunity for observation, says that he has not found them wholly soulless; that, if they are approached in the proper manner, they will, if it is just and right, oftentimes grant important concessions.—ED.]

ner, they will, if it is just and right, oftentimes grant important concessions.—ED.]

DUMMIES OR DIVISION-BOARDS.

BALLED QUEENS; QUEENS CRAMP; ALFALFA
A SUCCESS NEAR DR. MILLER'S.

By Emma Wilson.

Mr. Editor:—I don't quite understand your footnote on page 623. You say, "I very often pry over the entire set of frames clear to one side. This gives ample room for the removal of the division-board." Our frames are always pressed up tight against one side of the hive, leaving all the room possible for the dummy, to begin with. We could not possibly pry them any closer, no matter how much we might try, and I don't see how we could make any more room for the dummy than we have when the hive is first opened. Please tell us how your frames are arranged.

You also say that you call the dummy the division-board. Why? We have used both dummies and division-boards; and, while they are very similar, they are not exactly alike, and are not used for the same purpose. A division-board is used to divide the hive into separate parts, while a dummy is used to fill up space. Our dummies are smaller than our division-boards. If it is not incorrect to call the board in question a dummy, it is certainly better because shorter. If you don't call it a dummy, what do you call a dummy?

As I intimated before, the dummies seem to work all right in the hives with the latest Hoffman frames.

On page 635 George W. Martin says, after he clipped the queen she was balled; and on smoking the bees off he found her stung to death. I think that, if bees are left to themselves, they rarely sting a queen immediately after she is balled. Most likely, if he had closed the hive quickly he would have found the queen all right the next time he opened it—at least, it has worked that way with us. Blowing hot smoke directly on bees when balling a queen is about the surest way to cause them to sting her to death immediately. A very good way to free a queen, although it is an old way, is to drop the ball into water, when the bees will separate, and the queen can be easily picked up without any damage to her. I've never known a queen to be injured while freeing her in this way.

We had a very curious experience to-day, Aug. 27, while clipping a queen. Immediately after she was clipped she curled up and appeared to be dead or dying. She had caught her foot in the hind part of her body, and remained in that condition for some time. Just as soon as she was released she was all right again. Dr. Miller says he had read of such instances, but in all his experience he never saw any thing of the kind before.

About the first of August, while on our way to a Sunday-school convention, when we were six or seven miles from home I called the doctor's attention to a field of hay that was just ready to haul, by remarking, "Do you see that hay? It is the heaviest crop of hay I've seen for a long time." Dr. and Mrs. Miller were expressing their surprise when Dr. M. suddenly exclaimed, "I do believe it's alfalfa," and was out of the carriage very quickly, and found that it really was a large field of alfalfa. We halted and had quite a talk with the German who rented the place. He said that was the second crop they had cut this year. He was very enthusiastic in regard to its value, especially when fed to cows. He said this was the third year since sowing. If he could get such a crop of hay this year, when the hay crop was almost a total failure on account of drouth, it seems to me that alfalfa will prove to be a great boon to farmers. I wonder if it's not a little difficult to get a good stand in the first place. But, once there, it will come up of itself year after year. May be that's where our future honey crops are to come from.

Marengo, Ill., Aug. 27.

[Division-board is used by us in the catalog because it is an old name; and we don't like to confuse beginners by the change of a name, even though the new one might be, as it probably is in this case, more accurate. Experience that you and Dr. Miller can not appreciate has taught us the folly of these changed names when so *very* little is to be gained.

As you suggest, with the new-style Hoffman there is more room for the removal of the board than the old-style or real Hoffman. In the case of either, there are times when it is easier to take out a frame first. I myself follow no invariable rule.

I have had queens cramp in this way a number of times; but even when disengaging the foot, the "cramps" didn't go off immediately. I have had queens cramp or kink up their bodies when I was quite sure the feet were in no way responsible. I never knew the cramps to prove fatal to the queen.

In regard to the balling of queens, your experience is quite in line with ours.—Ed.]

THE POPPY

AS A HONEY-PLANT; HOW THE BEES REVEL IN IT.

By Em Dee.

There are a few facts a close observer may notice, though he be but a tyro in bee-lore. I have read, and heard mentioned, the many and various flowers from which honey-bees mostly obtain their substance, and this summer I have taken special interest in observing their caprices among the flowers in my front yard. Passing by all other blossoms that have been mentioned by old and interesting observers I come at once to the flower which seemed most to interest them, and which I have not elsewhere seen mentioned—the poppy. I have, perhaps, a hundred different flowering plants on the premises, and, by reason of frequent irrigation with the garden-hose, it may reasonably be conjectured how thriftily those plants are kept in growing mood. All flowers received a liberal share of attention—some more, some less—some for honey, some for pollen; but I can safely say that none were so sedulously courted, none so pronouncedly caressed, as the single poppies, often termed "golden-gate." Early morning found from one to half a dozen of the mellifluous insects upon each newly opened petal, and at dusky eve they were still to be seen actively filling their pockets with a pale-yellow pollen. But what most attracted me was the manner of their working, their reckless "bee-havior" in the frantic acquisition of the elements they wished to secure. Both Bro. York's Italians and the writer's German bees were equally rampageous. They had forgotten their staid and decorous methods, and now abandoned themselves to acts of apparent lawlessness. They pounced down, regardless of previous possessors, and rolled in the mealy substance until every pistil was divested of its golden powder, and off they go, heavy laden, to their homes.

The question uppermost in my mind was, and yet is, whether possible that they obtain some particles of the narcotic elements of the plant (the poppy being, as your readers well know, that from which opium is made), which, if so, would account for their hilarious antics;

or if the joy of feasting on so luscious and abundant supply reasonably accounts for the peculiarity noted.

The suggestion seems pardonable, that, in view of so effective pasturage, would not all bee-keepers do well to sow abundantly of seeds productive of so beautiful flowers as the poppy? A profusion of these glorious blossoms greets the industrious each morning, more attractive, in their various colors, than the rose. They require no special cultivation; any kind of ordinary soil is available; and the results in the bee-hive speak volumes in praise of the poppy.

And lest me ask "ye editor" if the special flavor Mr. Root noticed in Bro. York's honey—regarding which GLEANINGS asks—may not be solved by the suggestion just made; i.e., may it not be the poppy that has given the honey the unaccountably delicious "bookay"?

[It is possible; but I should hardly think there would be enough of such plants to make any appreciable flavor in the hive. It takes acres and acres of blossoms to make any sort of showing in the hive.—ED.]

HONEY FROM RED CLOVER.

Question.—Reading in one of my papers not long ago, I came across the statement that red clover is a honey-producer, while I have been told by my neighbors that it is not. Will you please tell us which is right? I am a beginner in apiculture.

Answer.—Well, perhaps both, as they view it from different standpoints. Red clover is certainly a honey-producer; in fact, I believe that red clover gives more nectar than any plant or tree I know of, not excepting that famous honey-producer the basswood, or linden. I never pulled the blossoms from a head of red clover yet but there was honey or nectar in them, no matter at what time of the year it was; and the result is always the same, year after year; so I think that the question should be settled by this time in the fact that red clover always secretes nectar, or produces honey, if you please. Now, this fact does not clash in the least with the statements of your neighbors who have told you that the honey-bee does not work on red clover, as that is what they undoubtedly mean by red clover giving no honey. A plant may secrete honey profusely, and yet the blossom be so shaped that the honey-bee can not reach this honey without the aid of some other insect to break open the corolla, as is the case with the flowers of the plant known as "comfrey," and with the blossoms of the common whitewood. In both of these the wasps and other insects bite through at the base of the flower to get at the

sweets, after which the honey-bee swarms about these bitten flowers and collects what the wasps do not consume. In certain seasons, and in some sections of our country, the corolla of the red clover grows so short, from drouth or otherwise, that the honey-bee can reach the nectar secreted by the blossoms, in which case we get large yields of honey from red clover, as was the case in this locality some years ago, when my yield from each hive averaged 60 lbs. of very nice comb honey, after the basswood and all the other flowers which yield white honey were out of bloom. In other seasons the secretion of nectar is fully as good as it was then; but the corolla is so long that it is of little use except to the bumble-bees, as wasps and insects do not bite the clover-tubes. Any person viewing the fields of red clover at this latter period, with a view of deciding as to the value of this plant to the honey-bee, would be apt to decide that "honey-bees never work on red clover." As a whole, we can hardly calculate on much honey from this plant, for there are far more years in which the bees get little or nothing from it than there are those when the hives show a gain while it is in blossom.

HONEY CANDYING IN THE COMBS.

Question.—A statement appeared not long ago in one of our papers, to the effect that honey rarely candies in the combs, the same being made without any qualifications. Is such the case? I am sure I have seen combs nearly solid with granulated honey.

Answer.—If the honey is left in the hive the year round, then the above is very nearly correct; but I have never, in my recollection, had sealed honey away from the bees over winter without its candying, except where it was kept in a room kept warm by a fire all the while. Now, while this candying of honey in the combs is of no great disadvantage when such honey is to be used by the bees for the purpose of feeding, yet it is a great misfortune to have much of it in partly filled sections which are to be used the next season as "bait sections," as they are termed, when they are used to start the bees at work in the sections earlier than they otherwise would. Where thus used the bees do not remove this candied honey, but, instead, put the new into the same section with it, which gives the section of honey, when completed, an uninviting appearance, thus causing the same to become nearly a drug upon the market. To obviate this difficulty, all the honey remaining in partly filled sections should be removed in early fall, either with the extractor or by placing them over colonies which need feeding, so that the bees may remove the honey and carry it down into the hives for winter supplies. The sections can now be stored away in good shape for future use.

TAKING SECTIONS OFF THE HIVES BEFORE THE CELLS ARE ALL CAPPED.

Question.—I am told that no section should

ever be taken from the hive till fully sealed over. Is this right?

Answer.—As a general rule this is good advice; but there are times when the yield of white honey is just over, and the yield from buckwheat or dark honey is about to commence, that a loss in price may be the result if this is strictly adhered to. Mr. Quinby said, and with much truth, too, that all boxes two-thirds sealed over, containing white honey, should be taken off before buckwheat honey was stored in them at the beginning of that yield, as partly capped boxes of white honey would bring more than when finished with dark honey. But I think I hear some one say, "If I take off honey before all the cells are sealed, it is liable to sweat and become sour." This is because the honey is kept in an improper place, such as a cellar or other cool damp place, where the best of honey will deteriorate in time, and become unfit for food. All honey should be stored in a dry airy room, which can be kept at a temperature of about 90° all the time, and in such a place the honey will be growing better all the while, whether sealed or unsealed. In this way it soon becomes so thick that the honey in these unsealed cells will not run out in crating; and if tipped over, not a drop will be found to daub the rest, which daubing is always spoken of as the reason why honey that is unsealed should not be removed from the hives. Thus I would always advise leaving honey on the hives till it is sealed, with the exception of times when other honey of an inferior nature is likely to be stored with it.

POLICY OF GLEANINGS ON TWO POINTS INDORSED.

Allow me to congratulate GLEANINGS on adopting two things as I urged. The first is raising queen-cells in full colonies. In the second, you are all right so far as you go, but you do not go far enough—that is, burning the foul-brood hives, combs, and frames. You expect the bees. No, sir. Burn *every* thing as you would poison ivy or smallpox rags. Then publish what you did, as a moral influence with others. When you find it within "7 miles," or 10 either, of you, urge the owner to burn the whole business after dark when every bee has been smoked in and fastened in. Don't waste time and brains arguing with us that the queen or bees will not infect other combs. Burn all.

If the owner lacks public spirit, or is too mean or shiftless to do it, then trade him a colony of equal description and weight from your own yard, then after dark smoke in the bees of

his infected colony; carry it to one side, and make a bonfire of it.

The diamond-shape trouble in sections in T super can be avoided by using another set of T tins at the top of the sections—that is, two sets of T tins for each T super.

Ingram, Pa., July 3. PHILO S. DILWORTH.

[Friend D., I entirely agree with you in your policy regarding foul brood. Ernest might not think exactly as I do, however; but after watching the thing for a good many years, I think I should sleep better to know that every thing pertaining to the business was thoroughly burned up.—A. I. R.]

ZINC TAGS.

We use zinc tags and write on them with a common lead-pencil. When we wish, after using these zinc tags, to clean them so that we can use them again, we use diluted hydrochloric acid and muriatic acid. The lead-pencil writing on zinc (old zinc is best) appears to be indelible.

Syracuse, Kan., Aug. 5.

Z. T. B.

NUMBERING HIVES AND LABELING TREES; CORRODED ZINC TAGS.

While you are discussing number-tags for hives, perhaps some of your readers would like my way, which is, to paint the numbers in large figures on the hives, using black paint. Sometimes it is quite a convenience to be able to read the number several rods away. Or if a tag is preferred, a good one can be made of a small square of old zinc; if slightly corroded, so much the better. Write what you wish on this with a black lead-pencil. I use a carpenter's pencil, which makes a wide mark, though the writing will remain legible for years if done with a fine-pointed pencil. These, tacked to stakes, are used by nurserymen to mark rows of trees.

By the way, I have used with much satisfaction a tree-label of the same material, which I saw illustrated in the *American Agriculturist* many years ago. The zinc is cut into a long triangle, an inch or more wide at one end, and eight or ten inches long, with the name on it thus:

BALDWIN.

The small end is then wound three or four times around a twig. It will not bind the twig so as to injure it, as it unwinds with the growth of the tree, and it retains its place until removed purposely.

BURDETT HASSETT.

Reliance, Va., Aug. 27.

BEEES IN A COFFIN, IN CHINA.

After I had seen bees in a table-drawer, in a box bed, under a counter, and under the floor of a Mohammedan mosque which is to be found here in Shaowu, I thought the possibilities had been pretty well nigh exhausted. But one day

I went up to a mountain village to visit a Christian. His father and mother were very aged, and, after the common custom of the land, he had their coffins all ready, finished up and varnished over nicely, in a shed adjoining his house. The cover of each coffin rested loosely on it; and a swarm of bees, finding a place large enough at the edge of one of the covers, had taken possession of the coffin.

This part of China abounds in woods and trees, yet I have never, but once, seen a swarm of bees in a hollow tree. That one exception was in an immense camphor-tree which stood just at the entrance of a village. Chinese bees seem to be almost as much domesticated as cats or dogs. They have no special attachment to any particular place or person; and if their hive becomes infested with moths, or in any way unacceptable to them, they abscond; but, so far as I have observed, they always locate in or near some human habitation. Buddhism makes a Chinaman loath to take the life of any thing not hurtful; and the coming of a swarm of bees to a house is considered a lucky event, bringing good luck. The operation of these two causes has made human habitations the safest place for bees for ages past, and the consequence seems to be a domesticated race of bees.

In this climate, where frosts are rare and severe freezes are unknown, we build our houses with a double wall made of lath and plaster, one on the inside, the other on the outside. This leaves an empty space, about six inches wide, between the two faces. One of our houses here is just now unoccupied, the family being away for the summer. A few days ago a swarm of bees, finding a crack between the mop-board and the floor of the veranda, located themselves between the walls of the house. This is another instance of the propensity of Chinese bees to locate themselves in human dwellings.

Shaowu, China, June 4. J. E. WALKER.

FAX.

Best time fer spreadin' brood is—after the brood has hatched.

Bees kin be united without enny fightin'—in the pupa stage.

Good queens will sometimes lay more eggs in the spring of the year'n the bees kin kiver.

If a feller knowed all about the hunny-bee he'd have to know all about God himself, and that is impossible.

I'd ruther be in it every yeer with a few good colonies well taken keer of than to be out of it half the time with a hull gee-raft.

I make my supers hump themselves so as to hold 32 sections, and, after keerful testin', I have found that a helthy kolony will complete that menny jist as quick as they will 24.

Baitin' supers is like feedin' katnip tea to young infants—it may not do enny harm, but does it axually do enny good?

By way of 'speriment, sirup made of granulated sugar wuz fed thick enuff to harden before the bees kapped it over, and the kolony pulled through the winter, owin' to the moisture in the atmosfeer, I s'pose.

Hybrid bees kin hear when they are tryin' to git at you through your veil, as the follerin' 'speriment proves: Set your teeth together and give the grand hailin' sign of a bee in distress by imitatin' the sound a hunny-bee makes when pinched, and thay will redouble their efforts to sting you. Try it.

If bees hain't protected frum heat, comb built on wired foundashun will sag in two er three seezins' use until drones will be razed along the top-bar. It's a fax.

Durin' apple-bloom, queen-cells wuz started; and then several days after, when they order o' knowed better, with hardly enny hunny left, and none comin' in, the bees k'menced throwin' off swarms—which is a proof that the presence of queen-cells is a powerful cause of swarmin'.

FATE.

See me, see me as I rush
To the lightin' board, and brush
Off my coat of yellow plush,
Ready fer a romp and play
Round the apiary to-day!
I'm a dandy, so thay say,
And for beauty stand alone
'Mongst the bees—and I must own
Up that I'm a *hand-picked drone*!
But, alas! the farmer's hen
Happened 'round that way jist then—
She belonged to the Shanghigh
Breed; and when she got her eye
On that drone she nabbed him by
His plush collar, and in two
Seconds he wuz gone frum view
In a happy "hum, sweet hum,"
Whare all bees must go to sum
Sweet day; and now he must own
Up that he's a *hen-pecked drone*!

Alexandria, Ind. ELLERY KRUM.

Bees have not done much for three years until the last two weeks. Now they are booming. It's from second growth of white clover, Japanese buckwheat or corn, or altogether. Prospect is good for fall honey. We have had abundant rains. THOMAS SHEPHERD.

Barry, Ill., Aug. 9.

Bees have done well this season. I have 3000 lbs. from 40 colonies, spring count, and 25 swarms. There are good prospects for 100 lbs. per colony, spring count. I am selling the honey at 10c per lb. This honey is all extracted, and fine quality. WM. MALONE.

Newbern, Iowa, Aug. 22.

COMMON SWAMP MILKWEED—ASCLEPIAS INCARNATA.

I mail you a flower to be named. It is becoming more plentiful here in my vicinity, and

is an A No. 1 bee-plant. I think it belongs to the milkweed family. Last year I got considerable surplus from it. The color is very light amber, and a peculiar spicy flavor not similar to any other honey I am familiar with. Here it blooms from July 1 to Sept. 1; and were it plentiful enough I would not exchange it for any honey-giving plant that grows here. Give me the proper and common name if you can.

Belleville, Ill., Aug. 20. E. T. FLANAGAN.

[The specimen, as nearly as we can identify it, is known as common swamp milkweed, *Asclepias incarnata*.—ED.]

THE *Kansas Bee-keeper* is growing better as it grows older. It has had a good start as a youngster, only nine issues old.

ALTHOUGH this is supposed to be the duller part of the year, we are full of business. Verily, the goods that go out from the Home of the Honey-bees are doing their own advertising.

SOME of the convention notes and comments will be found in A. I. R.'s talks in this issue. Others will be given by J. T. Calvert, in this department.

OUR newly equipped factory is being put in running order as rapidly as possible. A good many machines are now started, and we shall have all of them in full blast by the first of October.

THE frequent rains, and the abundance of fall flowers, especially of the great family of asters, give great promise of a fall flow of honey. Indeed, it is already coming into our hives now. Buckwheat is also doing well.

WE are again printing an extra number of copies as usual, and, for any thing we can see, shall have to do so for several numbers to come. Advertisers should not fail to take advantage of this extra circulation, for we charge no more for the space, although we add one-half to the regular number printed.

THE representative bee-women, including Mrs. L. Harrison, Mrs. Axtell, Miss Wilson, Mrs. Sherman, and Mrs. Heater, are shown up in half-tone on the first page of the *American Bee Journal*. It is a pity that so many of our representative women refuse to let us have their photos. Indeed, as it was, Bro. York, if I am not mistaken, had to take some of them by surprise.

A VERY pretty sight in front of our factory building is the merry humming of hundreds of bees on a couple of beautiful beds of portulacas. If we had acres of this, instead of ragweeds and other noxious weeds that do nobody any good, what might we have in the way of honey? If you haven't a bed of portulacas, better have one by another year.

QUITE a number of specimens of fall honey-plants are now being sent in to us for identification. Some of them have been forwarded, the sender asking if they were alfalfa. I could not imagine why there should be such ignorance regarding this plant until I looked the matter up. I then found there had never been a decent engraving made of this celebrated plant—at least, I had never seen one. The A B C of Bee Culture has one copied after a picture in a seed catalog, which was itself poor in the first place. I should be glad if our readers would refer us to a good engraving, or send us good specimens when the plants are in full bloom. I am determined that, by another year, there shall be a good picture, so that all may know when they see the plants, without calling in the services of a botanist.

FATHER LANGSTROTH AGAIN AT THE FORE-FRONT.

ONE of the notable features of the last convention of the North American at Toronto was the presence of that veteran of all bee-veterans of the New World, father Langstroth, the one man of all the world who gave bee-keeping its first real important start. Although he has been an invalid all his life, he still survives his 85th year. Indeed, his health has so far improved that he has resumed his pen. We already have one article from him, and the same will appear in our next issue. He hopes, health permitting, to finish up his interesting Reminiscences that were begun October 15th, 1892, and which, owing to the recurrence of his old head trouble, had to be discontinued in the May 1st issue of the next year. These Reminiscences were exceedingly interesting, and it was a great disappointment to us all that it should seem necessary to drop them when it seemed probable that, owing to his advanced age and ill health, they would never be completed. Mr. Langstroth is now at work upon them again; and, if all goes well, the hopes of his latter years will at last be realized.

BEEES AND COUNTY FAIRS, AGAIN.

OUR older readers will remember that we had trouble in times past by our bees helping themselves at the candy-stands while our county fairs have been in session from year to year, within a quarter of a mile of us. For the last two years you will remember we have drugged the bees with tobacco smoke, and cautioned the candy-men to kill the first few bees that

came around, and that they were not to let one of them get away with a load to bring back ten more. You will remember how well the scheme has worked. But this year our county fair was visited by some copious rains, and we therefore relaxed our usual vigilance in our apiary, thinking that the frequent rains would keep the bees in. It did, of course; but the sunshine came out at one time, and I went through the apiary to see what they were doing. I soon made up my mind that they were flying a little too briskly in the direction of the fairground to be engaged in legitimate business. I told our man to be on the lookout, and in the mean time I would go over to the fair. Sure enough, the bees were having a "perfect pow-wow" on broken watermelons. They had got started, and now the question, could we stop the mischief-workers at this stage of the proceedings? I hastily made my way back to the apiary, and both of us—the apiarist and I—began tobacco-smoking the strong colonies, first at the entrances, especially at those entrances where the bees were flying heaviest, and, presto! the flying ceased. After having gone over the whole yard, including the nuclei, I noticed that there were but very few bees flying. Again we went over the yard, this time to smudge the bees that had returned, and then I went back to the fair. It is almost unnecessary to say that there was a decided "let-up" on the part of the bees at the candy-stands and places where watermelons were sold by the slice.

You see, the tobacco drugged them; and as it takes them two or three hours to get over the effects, another smudging would last them nearly all day. The whole point of this is here: There will be more fairs yet in other places; and bee-keepers should take the hint in time, because they can not afford to have their bees declared a nuisance, or get into trouble with the "fair" people of our land.

MORE ABOUT THAT SALISBURY BEEF-DIET CURE —ITS EFFECT ON E. R. R.

I HAD fully matured my plans to be present at the Toronto convention, now a thing of the past; but a "temporary setback" in health at the time of going made it seem at the last minute inadvisable to leave home. A rigid following of the doctor's orders, and a strict adherence to the diet as explained in our previous issue, has brought me around all right. Indeed, I haven't felt so well in years.

As a good many have inquired after my health of late, being surprised that I had been "down" at all, I will say, for the benefit of those who may have been ailing like myself, and for those kind friends who have shown such friendly solicitude, that the Salisbury beef-diet cure is really performing wonders. Before I go further I want to say that this is no paid puff; so, keep that before you.

For several years back I have had indigestion,

chills, frequent attacks of grip, violent sneezing-spells—so violent, indeed, that I was seriously afraid of bursting a blood-vessel or something of that kind. In addition I found a growing incapacity for office work; dull headaches, accompanied by insomnia. Nervousness? oh, dear! I could have kicked the cat—any thing and every thing to relieve my pent-up feelings. Of course, I was on the verge of nervous prostration; and another one of those attacks of "la grippe," I believed, would finish me. Last winter, and this spring and early summer, the symptoms were worse. Bicycle-riding—that which had years before seemed to relieve me—was unavailing now; in fact, I hadn't strength enough to ride.

Now all this is changed. While I haven't recovered yet by considerable, it is evident that I am gaining rapidly. I sleep beautifully nights—that quiet, restful sleep that I haven't known for months; chills have all disappeared, and so have the sneezing-spells. Indeed, these last two disappeared in about two weeks' time from the beginning of that diet that means total abstinence with a vengeance, from every thing, almost, save ground lean meat. My normal strength and endurance are far from back, but are coming so rapidly that I have no fears but that they will have fully returned, and more.

Formerly when I ate my meals, even though I ate to the fill, I was not satisfied. I was starving to death with plenty to eat. Now I sit down to the table, and, even though my rations are limited, what I do eat *nourishes*, and gives strength; in short, I rise from the table now well and *sufficiently* fed.

Now, dear reader, if you are ailing as I have been, don't try to go on to this treatment alone without the advice of Dr. Salisbury, of New York, or Dr. Lewis, of Cleveland. I consult Dr. J. M. Lewis, 176 Euclid Ave., Cleveland. He has, under my own eyes, performed some remarkable cures—yes, saved even consumptives in the last stages.

In conclusion, let me say that neither Dr. Lewis nor Dr. Salisbury pays us one cent for this notice; and, indeed, we wouldn't take it from them, even if proffered, for they are not of the quack kind who seek notoriety through "great big puff ads." This statement, as was also the previous one by A. I. R., in the Sept. 1 issue, was written without their knowledge or consent. Our only motive is to help our fellow-men through the slough of despond, on to that plane—good health.

CAN QUEENS TRANSMIT FOUL BROOD?

R. L. Taylor, in the *Review* for September, while admitting that it may be possible for a queen from a foul-broody colony to transmit the disease to a healthy colony to which she may be introduced, rather doubts it. He took a queen from a colony badly diseased, and gave her to a healthy one, and this colony has pros-

pered through the season, and is perfectly healthy. A few years ago, when the disease raged with us so badly, I took at different times queens from a dozen badly affected stocks, and gave them to healthy ones. These remained healthy in every case. Of course, one swallow does not make a summer, nor do a dozen such swallows. But in all my reading on things apicultural, I do not know of one real good authentic case proving that a queen ever did carry the disease. The principal ground for belief in such transmission seems to be based on what Cheshire saw, or *thinks* he saw, as *Bacillus alvei* (foul-brood germs) in the ovary of the queen. In the first place, microbes are so numerous, and diverse in their character, that even the best of scientists are liable to be deceived; in the second place, even if the bacilli were actually there it does not follow that they would enter into the larvæ. All the facts and indications seem to show that Cheshire was mistaken. Where practice is at variance with theory, or, if you please, science, we will take practice every time.

THE ACTION OF THE N. A. B. K. A. REGARDING AMALGAMATION.

FROM the action taken at Toronto, the amalgamation of the North American Bee-keepers' Association with the National Bee-keepers' Union is all but a foregone conclusion. After discussing the matter pro and con, those who seemed to be opposed to the union of the two, and those who favored it, were very near together. The suggestion of Dr. Mason, in the September *Review*, was in large measure followed, except that the committee appointed to consider the matter, instead of waiting till the next annual meeting of the N. A. B. K. A. to report, is expected to complete its work within a month. It is then to report through the bee-papers, submit its findings to a vote of the members of the N. A. B. K. A., and also to the members of the Bee-keepers' Union, along with its next annual report. If accepted, the amalgamation is effected, and thereafter only one organization will exist in place of the two. The proposed name of the united organization is the North American Bee-keepers' Union. It is proposed to continue the office of the General Manager, elect a president, secretary, and treasurer, and board of directors, voting to be by mail, giving all members a vote, whether present at annual conventions or not. The defense fund of the Union is not to be impaired. One dollar, or whatever fee may be deemed advisable, will entitle any one to the full benefits and privileges of membership in the united organization, instead of one dollar in each, as at present. The benefits and advantages will be greatly increased, and at a less cost; and every bee-keeper in the land, who owns any considerable number of colonies, if it be not over a dozen, can not afford not to be a member.

The committee appointed were Thos. G. Newman, for chairman, and Dr. A. B. Mason, R. F. Holtermann, and J. T. Calvert, and three others whose names I do not now recall.

THE practice of circulating special circulars and dodgers, as was done at the last meeting of the N. A. B. K. A. during its sessions, was not very creditable to the writers of such matter, or considerate to those in attendance, especially the persons who happened to have the floor at the time. If the pet notions and supposed grievances of the writers of these circulars can not be brought to the attention of bee-keepers in any other way, it were better that they remain in oblivion. Such practices were condemned at the time, and always should be. We refer to the distribution of the pamphlet entitled "Bees," attacking Geo. W. York and others, by Frank Benton, and a dodger advertising a booklet by W. F. Clarke, defending sugar-honey production, and attacking Ontario's foul-brood inspector, Wm. McEvoy.

G. M. DOOLITTLE's genial face and eloquent words on some things of interest to bee-keepers were a treat indeed. The address deserved a larger hearing. His first plea was for more brotherly love, less desire for honor and self-aggrandizement, more willingness to impart, for the common good, valuable ideas gained in our own experience. "Freely ye have received, freely give." Along the line of honey adulteration he believed that more work (detective work if need be) and less talk would accomplish a great deal more. At present, though a great deal has been said, practically nothing has been accomplished to stop adulteration. Here is work which the Union ought to take up. If a few examples were made in convicting and punishing adulterators they would be more careful.

ONTARIO bee-keepers are to be congratulated for the strong and able allies they have in Hon. John Dryden, Minister of Agriculture, and Jas. Mills, President Ontario Agricultural College. Their able addresses at Toronto showed their deep interest in our chosen pursuit, and pledged co-operation as they have given it in the past. With such friends in high station it becomes an easier matter to obtain government grants to help make an organization of bee-keepers valuable.

THE paper by Allen Pringle on the mistakes of bee-keepers and bee-papers was a most excellent one, brim full of good points. To be sure, we could not all agree to all of the mistakes, but it would be strange indeed if no mistakes were made in treating such a theme.

THERE is some hope of the early publication of the report of the St. Joe convention if Mr. Benton carries out his pledge to the convention at Toronto.

THE TORONTO CONVENTION.

HOW I CAME TO GO.

"Doctor, do you mean to say your treatment will cure *all* kinds of chills, grip, hay fever, etc., in the short period of time that you have cured me?"

"Oh, no! certainly not."

"Well, then, how did you dare tell me that you would have my overcoat and trappings off, and have me clear of my chills, neuralgia, toothache, etc., and say I could stand the north wind, all inside of ten days?"

"Simply because I saw at once that you had no organic trouble. Your organism is all sound."

"Well, then, why can't I have a little rice or dry bread, such as you give Ernest and your other patients, to go with their meat? I am all cured of the chills, and what more do I need?"

"Because the chills, etc., were a secondary matter—a trifle compared to the real trouble and cause. We want to hold you down to the clean lean meat until you get over all tendency toward the chronic dysentery which has been getting a pretty fast hold on you of late. This tendency to constipation we are battling with is a part of it. We want to get this straightened out so your bowels will move regularly of themselves every day, or, at the furthest, every other day; then we can safely let you have a little variety with your meat."

"But, doctor, won't a sparing diet—that is, just a little of other kinds of food, so the patient can eat just what would be digested thoroughly, and no more—answer as well as, or almost as well as, this exclusively *meat* diet?"

"Being careful not to overeat, and eating just enough and no more, is a very important part of the treatment; but it is not all of it by any means. Lean meat as a diet has a special value. Other people have found this out, and it has been recognized for years. Your prize-fighters are trained on a beef diet; so with runners and the boat-rowers, the wheel-riders, and the base-ball players. They are cut off from tobacco, coffee, beer, and drink only pure water, as you do. They are also kept on lean meat until all useless weight is cut down. You see, we are really training you to be an expert wheel-rider. You have got your weight down from 135 to, say, 115; and pretty soon what you have left will be just the purest kind of muscle."

After I got home that evening I was thinking of it; and as I had been very busy during the day I got out my wheel by moonlight. Let me explain here that the doctor rather objected to having either myself or Ernest attend the convention. He said it would throw us out of our "training," and would interrupt the rations and hot water, and probably be quite a little setback to our progress; and Ernest decided finally that he could not stand the trip. It seemed to me, however, that at least one of us certainly *ought* to go. I sprang on my wheel, and started off by moonlight. The wheel seemed lighter than it had ever been before. The further I went, the lighter and prettier it seemed to run; and I soliloquized that, not only had I a feather-weight wheel, but, without knowing it, I had been almost unconsciously getting to be a feather-weight rider as well. God, in his infinite wisdom and mercy, had been opening up to me new and unexpected revelations. The air was just cool enough to make it exhilarating. As I covered mile after mile, up hill and down, my spirits rose—aye, and strength too; and I resolved then and there that I would go to the convention and show the doctor that

I could hold fast to my meat diet and hot water, and my new strength also, at one and the same time.

Before taking the boat in Cleveland I called on the doctor and told him what I wished to do, and he gave me directions; and to make sure of getting my needed rations I carried with me one ration ahead, to be eaten cold, if I could not do any better.

While sitting on the deck of the steamer enjoying the cool north wind with the rest of the passengers, some one remarked this was the night of the eclipse; and, sure enough, there was the moon shining down upon us in all her fullness, brilliancy, and loveliness. I knew that regular rest and sleep were as important as almost any thing else; but I had an old boyish longing to see that astronomical program carried out. On board the boat I secured a splendid tenderloin steak, and enough for a good full ration too. Then I took a nap, calculating to awake in time to see the eclipse start. I hit it almost to a dot; but thinking it would not do for me to watch it very long, I slipped out of my stateroom barefooted. I detected the commencement of the shadow before any of the rest of the passengers, and became so absorbed in it that I stood out there barefooted in my shirt-sleeves, notwithstanding the north-east wind (so much dreaded but a few weeks ago), and watched until the shadow completely covered the face of the moon. Then I went to bed satisfied—no chills, no toothache, no inconvenience. By the way, it was wonderfully interesting to see the host of stars, mostly invisible while the moon was out in full, come out one after another until the total eclipse. Then we had a brilliant starry night.

Notwithstanding the inroads made on my sleep, I slept so soundly that, before sunrise, I was up and dressed, and enjoyed one of the most brilliant spectacles of colored clouds, just before the sun came up, that I ever saw in this climate or any other. Another tenderloin steak on the boat in the morning fixed me for the forenoon. The hot water was furnished me free, with the utmost good nature, when I made a little explanation. Although I offered pay, none was taken. They said on the boat that, if a man took a notion to drink hot water, and nothing stronger, he ought to be encouraged by having it furnished free, even if he did drink cupful after cupful.*

* By the way, there is something wonderful in the way the patient relishes and enjoys his hot water after he has been three or four weeks on the meat diet. For many years I have been much in the habit, especially while riding the wheel, of drinking soda-water, ice-cream soda, and such like temperance drinks; and when the doctor told me these would have to be entirely cut off, I thought it was going to be considerable of a privation; but now when I saw all sorts of soda-fountains on the steamer, and iced drinks of every sort all around the Falls, I had no longing at all for any of them. In fact, above all the delicious drinks that art and skill have been able to manufacture, and you may, if you please, include all kinds of beer and intoxicating drinks, I could honestly prefer my pure hot water to each and every one of them. Ernest has repeatedly said the same thing. Why, here is something truly marvelous. Even the Keely gold cure can not compare with it. Suppose you could have a company of people—a band of *men*, if you choose, for men are most addicted to expensive and costly drinks—suppose we had a band of men in our land who actually *prefer* pure water to any thing else the world can furnish; what would be the result?

Meekness, temperance; against such there is no law.—GAL. 5:23.

And the bright and encouraging feature of it is, that I think almost any one—no matter how depraved his appetite may have become—can be, by such a course of diet as I have mapped out, led to

Close to the depot at Niagara Falls is a temperance hotel. I have often been told in traveling, that temperance hotels never furnish as good accommodations as the other kind. I know this temperance hotel at Niagara Falls is not that way. They gave me a place to lie down and take my nap, and then as much beef-steak as they give four or five ordinary guests, and charged me just the same as the rest of the crowd—40 cents for dinner. The place is neat, clean, and comfortable, and the managers are courteous and obliging.

As we had but little time at the Falls, a carriage was hired to take our crowd—Mr. Calvert, Constance, and Carrie. The children were greatly afraid I would tire myself out, even though I reminded them again and again that I was training for a racer or a wheel-rider, and I enjoyed the fun of running and jumping, up stairs and down, and getting ahead of them. You see I am light as well as strong. When we got on the islands of the Three Sisters I remembered my corns, for it was a pretty hot day, and I was taken with a great desire to wade in the rapids above the falls. To my surprise, however, they loudly protested, declaring I would fall down on the slippery rocks, and get washed over the great cataract, like ever so many other people from time immemorial, by their thoughtless folly. I was inclined to resent the imputation that the rapids could wash down a live Root who had his wits about him—espe-

prefer and enjoy *pure water* to any other beverage the world can afford.

No doubt much of the intemperance in intoxicating liquors as well as other intemperate eating and drinking, is caused by disordered digestion. The patient is restless and uneasy, and craves this, that, and the other; drinks soda-water, Hires' root-beer, etc., in the vain hope that it may hit his trouble and make him feel better. Give us a natural, healthy digestion, and pure water, when thirsty, and it satisfies better than any thing else that has been invented. Is it not so?

From the "Yearbook of the United States Department of Agriculture" for 1894 I quote the following:

"I have come to the conclusion that more than half the disease which embitters the middle and latter part of life is due to avoidable errors in diet, * * * and that more mischief in the form of actual disease, of impaired vigor, and of shortened life accrues to civilized man * * * in England and throughout Central Europe from erroneous habits of eating than from the habitual use of alcoholic drink, considerable as I know that evil to be."—SIR HENRY THOMPSON.

And from the same book I quote from an article written by W. O. Atwater, Ph. D., the following:

We consume relatively too much of the fuel ingredients of food—those which are burned in the body, and yield heat and muscular power. Such are the fats of meat and butter, the starch which makes up the larger part of the nutritive material of flour, potatoes, and sugar of which such enormous quantities are eaten in the United States. Conversely, we have relatively too little of the protein or flesh-forming substances, like the lean of meat and fish and the gluten of wheat, which make muscle and sinew, and which are the basis of blood, bone, and brain.

Another most important fact stares us in the face right here. You know something of the trouble I have had in finding water I could drink with safety when traveling, especially after drinking from different wells and springs in different localities. Well, on this Toronto trip I drank water from many different sources, from wells having water strongly impregnated with different chemicals; but the water, before being used, was first made boiling hot, then cooled, a little at a time, in a saucer; in this way I could drink a pint, or even more, without any harm whatever. I tried this so many times I think there can be no mistake. Boiling any water for drinking purposes answers a twofold purpose—it effectually kills organic matter or vegetable life in the water, and changes or precipitates, at least to some extent, what chemicals there are, in solution. Still further, a patient suffering with summer complaint, who can not drink cold water or water at ordinary temperatures, can drink water, as hot as the mouth can bear, as a general rule, without any distressing symptoms.

cially the father of the Roots then present. I heeded not their protests, but climbed down to the water's edge, tossing my shoes and stockings back at their feet to keep as mementoes if I got washed away. The folks on shore made such a fuss, however, I was really obliged to wade out of the water (which, by the way, was hardly knee-deep) and come ashore and forego my delicious pastime; but I felt as I can imagine a young duck does that has been hatched under a hen, and I told them I was coming some other time when they were not along, so I could have the fun of wading in Niagara Falls rapids to my heart's content.

John and I paid half a dollar for a water-proof suit to go down under the falls; but the girls thought they would stay on top. I did not feel satisfied to go out under the falls as far as the walk and railing extended. The guide said I could climb out on the rocks a little further if I wanted to. They guaranteed their water-proof clothing to keep us perfectly dry, so I walked out to the place where I could get right under a part of the fall. The wind swayed the broken-up spray one way and the other, so occasionally it would come all over me like a deluge. Once in a while the torrent was so great as to make me gasp for breath; but through it all there was a most delicious sensation (for it was a rather hot day) that for a time seemed strangely familiar. Finally I recalled that wheel-ride in the dark, when I passed through a foggy swamp where the air was so laden with vapor that it gave a delicious sensation like drinking water in filling the lungs with the damp water-laden air. Now, I have never heard this mentioned before; but I believe it is not only delicious but wholesome, during hot dusty weather, to wash out the lungs by breathing air so heavily laden with watery spray as to make you pant a little at times for breath. After I had enjoyed this until Mr. Calvert reminded me we would have to hurry back to the carriage, which was hired for only a limited time, I decided I could not go back without getting a better chance to kneel at the very foot of the great cataract. I saw a place where I could climb down through the rocks, and get clear into that boiling, hissing foam of mighty roaring waters. One little spot there seemed to be, right at the very foot of it all, where I could sit down and let the surging billows rush and roar up to my very feet. I got almost down there—in fact, one minute more and I should have been in the coveted retreat. Just as I was ready to slide down, however, there was a change in the program, and great waves of snowy, misty spray covered the spot entirely, and rolled up to my very feet. I am sure there would have been no danger of being washed into the boiling caldron; but the girls would certainly have had more cause for alarm had they been around just then. Now, why don't they have some iron rods for inquisitive Yankees to hang on to? or why don't they provide even a loose robe, so that people may safely dip into these delicious and entrancing waters, if they choose to? Why, to me the greatest charm of Niagara is to get right into the foam and suds, and be really a part of it.

I hate to find fault; but there is quite a little bit of humbug about the way the ticket-vendors advertise these places. The "light water-proof clothing" they tell about is a pretty good load for a man to carry, let alone advising women to go down there. And the "intelligent guide" who takes you around, and "explains" every thing, is a stupid, dirty fellow, smoking a pipe. He never volunteers a word unless you ask him a question; and then he seems to begrudge the time it takes to keep the

pipe out of his mouth while he answers in monosyllables. (This, too, on the *Canada* side.)

The great project of making Niagara Falls a water-power to move the wheels of the world is already in operation. Away up above the rapids, where I disturbed the children by wading in, a shaft has been sunk, hundreds of feet deep, so as to take the water from the *highest* point in Niagara River. A tunnel that has its opening near Suspension Bridge runs back into the rock about a mile, connecting with this shaft, utilizing the force of this water from its highest point, and letting it out at its very *lowest* point. This tremendous power is utilized by means of the latest and most improved turbine water-wheels; and these wheels move dynamos, and the great volume of electricity thus produced is carried by wire cables miles and miles, furnishing power wherever needed, and in quantity almost unlimited; and one of the beautiful things that this electric current is just now doing is propelling the cars of an electric railway down the gorge from the suspension bridge, through Whirlpool Rapids, Devil's Hole, and ever so many other points of interest, clear to Lewiston, on Lake Ontario. Although our tickets from Cleveland to Toronto covered this part of the trip, we cheerfully paid the small sum of 25 cents to ride down in the new street-cars on the Gorge Railway. Let me briefly explain: Lake Superior is considerably higher than Lake Huron, into which it empties; Lake Huron, in turn, is higher than Lake Erie, just below, and Lake Erie is several hundred feet higher than Lake Ontario, the fall in one place between the two lakes being 160 feet sheer perpendicular, constituting what is known as Niagara Falls.

We took this gorge railway and descended by the electric elevator 230 feet down the cliff. But even when we had reached the bottom we found Niagara River just roaring and raring as it pitches headlong still further down into this rocky gorge with the cliffs more than 200 feet high on each side. It goes down hill in this headlong way for all of a mile, and this makes the wonderful gorge. The new railway, just completed, is cut in the side of the rock at times almost down to the water's edge. Mr. Calvert asked one of the managers how long that project had been in operation. The reply gave me a quick start of pain. He said:

"We made our first trip just two weeks ago last Sunday."

I have not the full particulars; but as soon as he spoke I remembered hearing of a terrible accident, resulting in the loss of life, about the time they opened this new railway. God has given us this wonderful new force, electricity. He has given us the new means of rapid travel by these beautiful and unique electric railways. Is it really true that the United States of America is getting into a fashion of celebrating each new gift from the great God above by trampling upon and desecrating his holy Sabbath? They start new street-railways on Sunday; and when our American boys and girls want to demonstrate what may be done with this other new gift right from the great Father above, the modern wheel, they pick out God's holy day on which to demonstrate that they can ride a hundred miles between sunrise and sunset. This country professes to be a Christian nation; yet right over the line, in the city of Toronto, a great city of about 200,000 inhabitants, not an electric car or any other kind of street-car moves a wheel on Sunday. I asked some of the people how they managed to go to church without the aid of street-cars. You know folks in the large cities here in the States claim that the cars are an absolute

necessity for the people to go to church. Well, one of the Toronto friends replied something as follows:

"Mr. Root, if you will consent to remain over Sunday with us I think I can show you that a greater proportion of the people of Toronto attend church regularly than in almost any other city you can find of its size in the world."

While in Buffalo I unexpectedly ran across our big good-natured friend Dr. Mason; and he was, as he always has been, a great part of the life of our convention. J. B. Hall, of Woodstock, Ontario, kept up his reputation, not only as a successful thorough-going bee-keeper, but he has not forgotten his comicalities and dry jokes. He said that, the next time I wanted a milder climate than that of Ohio to spend the winter in, I should come up and live in Canada. He said they would send me back with plump and rosy cheeks, something after the fashion of my son-in-law, Mr. Calvert, and the rest of them who were brought up in Canada.* Father Langstroth, with his accomplished daughter, Mrs. Cowan, was present, I believe, during all the sessions. T. G. Newman; W. F. Clarke; R. H. McKnight; Hutchinson, of the *Review*; York, of the *American Bee Journal*; Holtermann, of the *Canadian Bee Journal*, and Frank Benton, from Washington, were all present; and the greater part of our deliberations were characterized by brotherly feeling and brotherly bearing. Once or twice, when I was not present, somebody said there was a little jangle. Matters that did not seem to settle themselves quickly were very soon referred to a committee, so that comparatively little time was wasted in unimportant matters. Father Langstroth gave us a history of the difficulties attending the landing of the first Italian bees on American shores, about the year 1859. Mr. Parsons, the celebrated florist and rose-grower, made about the first successful shipment. But he was no bee-keeper; and after he got his bees here safe and sound he was so very careful and kind (?) to them that he first put them into a greenhouse. After the greater part of them had buzzed their lives out by bumping against the glass he put them outdoors in an antiquated bee-shed; but somebody told him they would surely go off and get lost unless he shut them in. So he covered the bee-shed with mosquito-netting. And this was a time when cherry-trees, apples, and pears were all in full bloom, and the common black bees just reveling in the blossoms. The poor Italians were kept inside by the cruel netting. After the six colonies were almost used up he sent for his old friend L. L. Langstroth to come and try his hand at saving them. They had been feeding them honey inside of the netting. The poor bees were daubed up, discouraged, and many of them dead; and, after doing his very best, friend Langstroth saved just a single queen. Somebody from California wanted the Italians so bad that he actually offered \$500 in gold for the single surviving queen; but Parsons

* In his talk about wintering bees in the cellar (for I believe cellar wintering seems to be best during the long severe Canadian winters) he spoke of the contented hum that should tell the bee-keeper when every thing is just right; and even when he was talking—at least so it seemed to me—a cheerful, gentle hum began to diffuse itself throughout the whole large room in which the convention was held. I thought at first it must be an accident; then I stared at our friend, and wondered if it were possible that he was a ventriloquist as well as humorist. There was no mistake about it. The well-known buzz that seemed to be here, there, and everywhere, instead of emanating from any particular point, must have been the result of a ventriloquial effort on the part of our comical and irresistibly quaint veteran, J. B. Hall.

would not let her go. Then there was a craze for more importations, and others finally succeeded. It was not very long after this time that I got the bee-fever, or the Italian-bee fever, as you may remember from the introductory pages of the A B C book, and I paid \$20.00 for my first Italian queen, and it was a good investment.

T. G. Newman presented the matter of the Bee-keepers' Union. I will explain to our readers who are not familiar with this organization, that a certain number of bee-keepers throughout the United States and Canada club together and pay \$1.00 a year for the purpose of keeping a reserve fund for employing legal talent when any individual or town, or any locality, takes it into its head that bee-keepers have not the right to live and do business. Of late years the Union has succeeded in settling most cases of litigation by simply showing its record in the past, and letting the world know that it has a reserve fund that may be used to employ the best legal talent to defend our rights. Of course, this money is expended only for the protection of its members.

For years back, most readers of the bee-journals have enjoyed the writings and the instruction given us regularly by our good friend Doolittle. In fact, his is almost a household name in every family where a bee-journal is taken; but I never knew until now that friend Doolittle was an orator as well as a writer. And I want to whisper to the friends in his vicinity, that, in case the minister should be absent on a vacation or otherwise, friend Doolittle is abundantly able to give them an excellent sermon, fit for Sunday or any other day. I want to repeat just one little story he gave us, because it contains an excellent moral:

When Henry Clay got to be something of a public man, on a certain time it became very desirable that he should have the friendly services of one who had in days gone by been an old schoolmate. This friend, however, had been put out by something not according to his ideas of justice and right. He flatly refused to give Mr. Clay any aid or encouragement. The great orator plead his case nobly. He reminded his friend of their boyhood days—of the time when they had been almost inseparable, winter and summer, as they studied and played together. Said he, "James, do you remember that old flint-lock musket our fathers used to let us have to hunt with?" James nodded. "Do you remember how many times it brought down the game, and did wonders for such ancient artillery?"

His friend's face softened a little at the memory of bygone days, and he nodded again.

"Well, this old flint-lock musket failed us once or twice."

By this time James had relented enough to supply an incident or two in the narrative. "Yes," said he, "I do remember one critical moment when I stood face to face with a bear; and, although it had not failed me once for a very long time, the obstinate thing at just this critical point, when it was almost a matter of life or death, refused to go off."

"Well, James, did you throw the musket away and declare you would never have any thing more to do with it?"

"Why, no, I remembered how faithful it had been previously; and as there was not really any thing very much better to choose from away back in those days, I 'picked the flint' and tried it again."

"James, you have just said you would never forgive me for that one foolish act away back years ago. You surely do not mean to say that you are going to throw me over, and treat me

with less consideration than you would an old flint-lock musket, do you?"

James threw his arms around his old comrade's neck, and in his turn begged forgiveness for being so stubborn and obstinate, and they were friends ever afterward. Dear brother bee-keeper, does this story come home to you? Is there one in our ranks who has done some foolish thing? and have you been more foolish still in declaring in your heart, even if you have not said it in words, "No, I will never forgive him nor forget the injury?"

Praise ye the Lord; for it is good to sing praises unto our God.—PSALM 147:1.

One strong inducement to go to Toronto was an exceedingly kind letter from Grainger Brothers, florists and market-gardeners, out in the suburbs of Toronto. It rained the evening we came into the city; therefore next morning at daylight it was a splendid time to look over flowers, fruits, and vegetables. As soon as I could manage to get my rations of beefsteak at the hotel I was off on the beautiful new street-cars that go everywhere in Toronto. How customs do vary in different cities! In Toronto you do not put your fare in a stationary box, neither do you hand any money to a conductor. The conductors are all prepared to give you six tickets for 25 cts. Each ticket will take you anywhere in the city. Just say where you want to go, and the needful transfers will be cheerfully furnished. The conductor never takes your ticket, however. He simply presents you with a machine looking something like a coffee-pot, and you are expected to drop your ticket down into the glass nozzle. If you haven't any ticket, of course he sells you one or more. At the close of his day's work I suppose he hands over the unsold tickets and the money, and they should just tally. The coffee-pot is also handed in, and the tickets counted. When I looked inquiringly at said coffee-pot, the young man who carried it explained it very cheerfully. You see, they are accustomed to receiving visitors.

Friend Grainger was away, out in the gardens, among the wet grass and dahlias, and other flowers decked with dewdrops. His obliging and efficient assistant very courteously took me over to the place, and showed me the sights on the way. Grainger Brothers have several ranges of greenhouses that made me think I was in Pleasant Hill, Mo.; but they were not quite as extensive. Off through a pasture-lot we went, and climbed over the fence. Here was an apple-orchard with the trees bending with the most beautiful fruit, perhaps, I ever saw; and underneath the apple-trees, occupying almost every foot of ground, were great gorgeous dahlias—some of them as big as saucers (or a little smaller). This, you see, is gardening again under the shade of the trees, such as I described in Florida. On every hand I saw something that came from the Home of the Honey-bees. They put the Ignotum tomato at the head of all others, with the exception that it rots rather more than some others—the Atlantic Prize, for instance. These beautiful dahlias are shipped away down to the States, and among their customers are the seedsmen Dreer, Pitcher & Manda, and others familiar to greenhouse-men. But, didn't we talk tomatoes, sweet corn, spin-

ach, and every thing that grows in the garden! Just now, however, garden-stuff is very low in and around Toronto. Nice potatoes are retailing at 25 cts. a bushel; tomatoes about the same. Green corn has been hawked about the streets for 4 cts. per dozen; string beans, 10 cts. a peck; cucumber pickles, 15 cts. per 100. The recent rains, you see, have sent every thing forward all at once. Friend Grainger admitted it hardly paid for picking; but somehow it seemed easier for the men and horses to go through the motions than to stand still and give up. Besides, if they give their patrons great bargains just now when every thing is so plentiful, they will hold the trade, and may expect said patrons to turn around and give them a lift when prices are higher again.

The Graingers have a way of fixing their hot-water pipes that may not be new, but it was new to me. They use four-inch pipes with bell-shaped coupling, and the joints are made with Portland cement and water—nothing else. They told me, however, that, to get the best results, put the pipe together, put in your cement, set every thing as you want it, leaving a little opening on the upper side of each joint. After the cement sets hard, and you are ready to put in the water, then cement up these openings, or vent-holes, the very last thing. When put up in this way he says he has never had a leak. The hot water never disturbs the Portland-cement joints.

After we had looked around the home garden and admired the great masses of bloom, we took the horse and buggy and went further into the suburbs. Most of the soil round about Toronto is just the thing for market-gardening—a sandy loam—and a great deal of it quite rolling. The rolling land is just right for fruit. In one twenty-acre lot we saw apple-trees with the limbs just breaking down with the most beautiful, smooth, clean, handsome fruit. Between the trees was a rank, thrifty crop of sweet corn; and between the rows of sweet corn were great quantities of Hubbard squashes—three crops on the same ground. But I suppose the secret of it was the great quantities of manure drawn from the big city. This twenty-acre piece contained a great variety of crops of all kinds; but the owner had not yet learned the importance of having the stuff in long rows. He had square beds of one thing and then square beds of something else.

Oh! I must not forget to mention the beautiful Prizetaker onions. Some of them looked like little cabbage-heads. They were piled up in front of the groceries all over Toronto. Friend Grainger tells me they are transplanted onions, and are now produced all over Canada. He said he believed he started the thing first, and he got it from the Home of the Honey-bees.

Before getting around to the bee-keepers' convention I was treated to a glimpse of the trial grounds of Steele Brothers, of Toronto. There we saw all of the late and much-talked-of tomatoes, each one trained on a handsome wooden trellis, all in full bearing, the first of the tomatoes getting dead ripe, and not a tomato yet picked. As I told you, the Ignatum holds its own in Canada about as well as any other, only that it roots more in dry seasons than some others. Livingston's Buckeye State may, perhaps, be preferred by some; but the Fordhook Early, from Atlee Burpee. I think showed the best for an extra-early tomato. Oh what a beautiful place—that was to test gardening! The only trouble—if it could be called a trouble—was, that the ground was so rich that almost every new vegetable showed to advantage. Why, their trial crop of cabbages was the finest cabbage-field I ever saw in my

life anywhere. I should hate to be obliged to load some single heads, leaves and all, into the market-garden wagon. But then, you see I am on beefsteak diet just now, and that may have a bearing on the case.

On our way home my companion asked me how much I remembered of him. I replied that we had corresponded more or less for many years about greenhouses and mushrooms, transplanting onions, etc. "But," said he, "I don't believe you know even now just who it is who is riding by your side. Do you remember that, years ago, a boy wrote you to the effect that he was working for a man who was a confirmed skeptic; and, notwithstanding what GLEANINGS said, it seemed to him, this boy, that Christians were not as honest and upright in deal as people who make no profession, or skeptics, if you choose."

I did recollect some such letter away back in the past. He went on:

"Just about the time my parents were lamenting that I was straying away from the faith, I got hold of a single number of GLEANINGS, and it gave me a glimpse of the real worth and value of true religion as a force or motive power in the business world I had never got hold of before. To be brief, I dropped my unbelieving employer, and, through the influence of the Home Papers, I chose Jesus Christ, and commenced the Christian life. Along with my Christian sentiments I took to gardening and greenhouses. You have seen the outcome, or, at least, some of it. At first my wife did not take much interest in GLEANINGS, thinking it was gardening, bees, and such things, out of a woman's line. One evening, however, I picked out an old number and asked her to read a little of A. I. Root's talks. She asked for the next and the next, and I could hardly get her to go to bed that night; and in a very short time she had read the Home Papers up to date; and now you know why I was urgent in my invitation to have you make one of our little household. In the evening I was pretty tired and asked to go to bed early.

Oh! I almost forgot to tell you there is a baby in that household. Of all the beautiful flowers that the greenhouse and all outdoors combined can show, there is none brighter or prettier or sweeter than that baby; yes, and I might include as well another one that is a little too old to be called "the baby" just now.

After bidding them all good-night, baby included, I went up to my room. I wonder if any body else knows what dainty, pretty, tasty sleeping-rooms there are in "our neighbors'" homes all over our land. In fact, I should not know it, if I did not get around among my neighbors now and then. On the dainty little stand with its pretty spread I found the latest thing in the way of a handy Bible. Tired as I was, I selected one or two of my favorite passages. By the way, for weeks back every now and then there has been welling up from my heart the words.

Praise God, from whom all blessings flow; and as the sweet strains of music came up from the room below, I joined my prayer with their praise. Friend Grainger loves music as well as flowers, fruits, and vegetables. He is a leader, or something of that sort, of their Sunday-school choir. The young people of the neighborhood had gathered in with violins and violoncello; the sweet voices accompanied the piano in practicing for the next Sunday morning service, for this was the regular night. I laid my tired frame in the soft sweet bed, and, with the blinds thrown wide open, until the pure fresh air came right across my face, I lost consciousness with praises to God upon my lips.

The greenhouses and the flowers, and that little home, rejoiced my heart; but, oh! a thousand times more did I rejoice to see young boys and girls growing in wisdom's ways, and stepping heavenward—yes, the childish voices to be heard above the music, practicing hymns of praise, were to me the sweetest music ear ever heard.

After dinner, while standing on the hotel steps of the Palmer House, a man approached me and introduced himself as James Storer, of Lindsey, Ontario, a locomotive engineer. He said he had begged leave of absence for just a few hours in order that he might meet A. I. Root, and he came pretty near not finding him. It was not bees he wanted to talk about, although he had been a bee-keeper years before. Through the bees he got hold of GLEANINGS; and through GLEANINGS, nearly fifteen years ago, he was induced to give up the use of tobacco. Before he dropped it, however, one of his four boys had acquired the habit. That boy uses it still. The three other boys do not, and could not be hired to. Said friend Storer, "Mr. Root, if you were to give me \$500 in gold to-day, and furnish me, free of charge, the best tobacco that the world can produce, all the days of my life, I would not think of touching it; and I came here to thank you in behalf of my boys, in behalf of my wife, and in behalf of all my children—in behalf of Christ Jesus, our common Savior, for the good you did in winning me from that bad habit. Your Tobacco Column presented it in a way that I could not take offense. You reminded me of my boys, who would surely follow their father's example; and I said that, God helping me, I would not be a slave any longer. To-day I am a free man, and am rejoicing in better health; I am rejoicing in cleaner habits; I am rejoicing in a clear conscience. Keep up the Tobacco Column, and never let it drop, or be crowded out." Of course, the above are not his exact words, but I think they are not very far from them.

ALFALFA IN NEW YORK.

On the steamer on Lake Ontario I formed the acquaintance of E. A. Stratton, of Horseheads, N. Y. He told me he was a market-gardener. In May, a man to whom he had rented one acre went back on his contract, and the ground lay idle. He plowed it up and sowed half a bushel of alfalfa seed. By the middle of August it was two feet high, and he cut it and got a tremendous crop of feed. It was about a third in bloom when cut. The day he left home, Sept. 5, it had grown to a foot in height since cutting. Of course, this stand will winter safely—at least, I should suppose it would; and if this can be done in Chemung Co., N. Y., why can't it be done in other places? Friend S. said they were having a heavy yield of buckwheat honey. He had already secured 50 lbs. to the colony, of comb honey, and it was selling readily at 10 cts. per lb.

THE GAULT RASPBERRY.

Mr. Root:—In response to your request of Aug. 1, I will say that I have good prospects of getting 50 plants from the single Gault raspberry sent me this spring. There are now over 40 canes ready to layer, and they are are still

growing more. It has not attempted to blossom so far this season. I am much pleased with the way it grows; and as soon as I test its fruiting here I will plant largely if satisfactory. Unionville, Mo., Sept. 2. E. F. QUIGLEY.

The Gault raspberry has, from the one plant I got of you, given 30 nice plants, now growing. They are all the way from blossom-buds to ripe berries, loaded. I laid down the canes and covered three and four places with dirt like this: —o—o—o—o—and I raised good plants, by what you may call "layering." The consequence was, the layering plants threw out a shoot near, or about the surface of the ground, and these shoots gave what is called the early or first crop; then afterward they threw out good strong shoots from beneath the ground. By this time you can hardly tell which were the tip or layer plants. JOHN SLAUBAUGH.

Eglen, W. Va., Aug. 30.

ENEMIES OF THE CLOVER.

Mr. Root:—Perhaps I can give you the information desired by C. C. Welsh, of Fostoria, O., concerning the clover midge. The clover midge is a minute fly, or midge, which destroys the corolla of the red clover, *Trifolium pratense*, the larvæ of the midge eating out the heads until they have a blasted look, destroying the organs of reproduction, and sometimes causing whole fields to be barren. The heads as they ripen sometimes appear as though they had been sheared, or the corolla plucked out. The above is enough to make any one entirely familiar with the work of the midge, which, when full grown, is not $\frac{1}{16}$ inch in length.

Now concerning the worm mentioned by Mr. Welsh. It is undoubtedly the *Phytonomus punctatus*, an insect that attacks young clover-fields in this State in immense numbers, and, were it not for the fact that the insect itself is attacked by a fungus here, it would in a very short time exterminate the trifoliate family from our State, as, early in the spring, the sod seems packed with them. The symptoms of attack by the fungus will be known by seeing the worms suspended from grass-blades, where they soon die and dry up. This symptom should cause joy wherever seen, as it is a sign of no further damage.

Buckwheat honey is rushing at present.

Baptisttown, N. J., Aug. 26. W. W. CASE.

BUCKWHEAT FOR PIGS.

Mr. Root:—Can you give me the results of feeding hogs on buckwheat? Is there any trouble in pasturing hogs on fields of it? I have an idea that we can raise pork cheaper on buckwheat than on any thing else, if it is healthful. The only fear I have is that it may give hogs a cough. I have some fine lots that I will turn my hogs into soon, if I learn nothing unfavorable. Last fall I had a small lot, and let my pigs go in it. The results were wonderful, although the animals coughed a good deal, but no further trouble. I hope to hear from you with any information you can give, so I will give the results of this season as soon as over. I counted 290 grains of buckwheat on one stalk, and still fresh blooms coming. Of course, it was a select stalk, but only an average of the best. Goldston, N. C., Aug. 16. J. M. STINSON.

You have got us here rather out of our beat. I do not know that I ever before heard of buckwheat for pigs, but doubtless our readers can give you points in the matter. I can hardly believe that the buckwheat, as they ate it in the fields, had any thing to do with the cough. If

it should transpire that buckwheat is a cheap pork-producing plant, it would be another thing in its favor. Years ago I wrote about keeping poultry without any care or attention by sowing buckwheat for them, say every week during the season. It was because our hens did so well when we had a field of buckwheat close to the poultry-houses, and because some of the biddies went out into the field, stole nests, hatched great broods of chickens, and reared them, not only without any care and attention, but without any knowledge on the part of the owner, until the mother paraded a great brood, old enough to be past the danger-line. Another thing that pleases me is to know that buckwheat is a success as far south as North Carolina. I thought it was rather a cold-weather plant.

ABUNDANCE PLUMS.

Mr. Root:—Your mention of Abundance plums, page 607, will no doubt cause many of your readers to plant them, which is all right; but I wish to add a word of caution. Many of the Japanese plums bloom too early, and get frosted. Then many nurserymen bud them on peach-stocks, which is a mistake that the planter will have to bear. All plums should be budded on plum-stocks. The following are the best of the Japan plums: Abundance, Burbank, Red June, Chabot, Orient, and possibly a few more. They are a beautiful tree, and fruit brings a good price in the market. In planting for market I chose Abundance and Burbank, and will add Red June and Orient at my next planting. I will favor the readers of GLEANINGS with my success with these plums in North Missouri as soon as they commence bearing. Being interested in horticulture, I should like to know how your Rocky Mountain cherries have fruited.

FREEMAN POTATOES.

I planted a barrel of Freeman potatoes, and am well pleased with both the yield and quality, though they are not quite so early as expected. I followed the Terry plan of planting and cultivating. **E. F. QUIGLEY.**

Unionville, Mo., Aug. 6.

The trouble here, friend Q., with the Abundance plum, is as you mention—they are very apt to be cut off by late frosts. A neighbor of ours has an orchard of toward 100 trees, and last spring they were loaded with green plums; but the frost took every one of them. The frost also took every one of our Rocky Mountain cherries; but our experiment station secured some fruit, and they tell me they are more like an enlarged wild cherry or choke-cherry than the tame cherries that grow on our trees. I fear that the nurserymen have overstated in regard to the quality of the fruit.

HUMBUGS AND SWINDLES.

A subscriber sends us a part of a periodical that calls itself the *United States Health Reports*. On this clipping there is a big boom of the California cold process of preserving cold fruits, signed by Mrs. M. A. Curter, Englewood, Ill. She tells how a poor woman can make one or two hundred dollars around home in a few days by selling the secret for a dollar. Anybody who wants to sell you a secret or a recipe for doing any thing for a dollar or any other sum, had better be turned out of doors to start with; do not parley or argue. Get him clear off your premises as soon as possible, for all such things are humbugs and swindles. This poor woman says she will send samples of the fruit,

with full directions, for 18 two-cent stamps. I do not know whether she sends any thing for the stamps when she gets them, or not; but the thing is an old humbug and an old swindle. On the other side of the paper we read:

"Indorsement of the United States Health Reports, July 19, 1895."

Then they go on to tell that the United States has indorsed the Perfection Manufacturing Co.'s dish-washer. The washer may be a very good thing—we don't know; but the puff of the thing is an out-and-out swindle. It is a little significant, but not at all strange, that, on the same little clipping, we find a denunciation of preachers in general. One would think this United States Health Report had a special dislike or dread of the very word "preacher," and well they may have. We have looked in our commercial reports for the standing of the Perfection Manufacturing Co., Englewood, Ill., but the quotation is blank, blank. Look out for all such advertisements.

Books for Bee-Keepers and others.

Any of these books on which postage is not given will be forwarded by mail, postpaid, on receipt of price.

In buying books, as every thing else, we are liable to disappointment if we make a purchase without seeing the article. Admitting that the bookseller could read all the books he offers, as he has them for sale, it were hardly to be expected he would be the one to mention all the faults, as well as good things about a book. I very much desire that those who favor me with their patronage shall not be disappointed, and therefore I am going to try to prevent it by mentioning all the faults, so far as I can, that the purchaser may know what he is getting. In the following list, books that I approve I have marked with a *; those I especially approve, **; those that are not up to times, †; books that contain but little matter for the price, large type, and much space between the lines, ‡; foreign, §. The bee-books are all good.

BIBLES, HYMN-BOOKS, AND OTHER GOOD BOOKS.

As many of the bee-books are sent with other goods by freight or express, incurring no postage, we give prices separately. You will notice, that you can judge of the size of the books very well by the amount required for postage on each.

MISCELLANEOUS HAND-BOOKS.

5	An Egg-Farm, Stoddard**.....	45
	Amateur Photographer's Hand-book**.....	70
5	A B C of Carp Culture, by Geo. Finley.....	35
5	A B C of Strawberry Culture**By T. B. Terry	35

Probably the leading book of the world on strawberries.

	Barn Plans and Out-Buildings*.....	1 50
	Canary Birds. Paper.....	50

2	Celery for Profit, by T. Greiner**.....	25
---	---	----

The first really full and complete book on celery culture, at a moderate price, that we have had. It is full of pictures, and the whole thing is made so plain that a schoolboy ought to be able to grow paying crops at once, without any assistance except from the book.

8	Domestic Economy, by I. H. Mayer, M. D.**	60
---	---	----

This book ought to save at least the money it costs, each year in every household. It was written by a doctor, and one who has made the matter of domestic economy a life-study. The regular price of the book is \$1.00; but by taking a large lot of them we are enabled to make the price only 60 cts.

	Draining for Profit and Health, Warring.....	1 50
10	Fuller's Grape Culture**.....	1 40

	Farming For Boys*.....	75
--	------------------------	----

This is one of Joseph Harris' happiest productions, and it seems to me that it ought to make farm-life fascinating to any boy who has any sort of taste for gardening.

7	Farm, Gardening, and Seed-Growing**.....	90
---	--	----

This is by Francis Brill, the veteran seed-grower, and is the only book on gardening that I am aware of that tells how market-gardeners and seed-growers raise and harvest their own seeds. It has 166 pages.

12	Gardening for Pleasure, Henderson*.....	1 85
----	---	------

While "Gardening for Profit" is written with a view of making gardening PAY, it touches a good deal on the pleasure part; and "Gardening for Pleasure" takes up this matter of beautifying your homes and improving your grounds without the special point of view of making money out of it. I think most of you will need this if you get "Gardening for Profit." This work has 404 pages and 203 illustrations.

12	Gardening for Profit.....	1 85
----	---------------------------	------

The latest revision of Peter Henderson's celebrated work. Nothing that has ever before been put in print has done so much toward making market-gardening a science and a fascinating industry. Peter Henderson stands at the head, without question, although we have many other books on these rural employments. If you can get but one book, let it be the above. It has 376 pages and 138 cuts.

	Gardening for Young and Old, Harris**....	1 25
--	---	------

This is Joseph Harris' best and happiest effort. Although it goes over the same ground, occupied by Peter Henderson, it particularly emphasizes the thorough cultivation of the soil in preparing your ground; and this matter of adapting it to young people as well as old is brought out in a most happy vein. If your children have any sort of fancy for gardening it will pay you to make them a present of this book. It has 187 pages and 46 engravings.

10	Garden and Farm Topics, Henderson**.....	75
	Gray's School and Field Book of Botany....	1 80

5	Gregory on Cabbages; paper*.....	25
5	Gregory on Squashes; paper*.....	25
5	Gregory on Onions; paper*.....	25

The above three books, by our friend Gregory, are all valuable. The book on cabbages especially is good, teaching you almost anybody, whether they raise squashes or not, the trick at the very foundation of success in almost any kind of business.

10	Greenhouse Construction**.....	1 40
----	--------------------------------	------

This book, by Prof. Taft, is just out, and is as full and complete in regard to the BUILDING of all glass structures as is the best book in regard to their management. Any one who builds even a small structure for plant-growing under glass will save the value of the book by reading it carefully.

15	How to Make the Garden Pay.**.....	1 35
----	------------------------------------	------

By T. Greiner. This is a new book, just out, and it gives the most explicit and full directions for gardening under glass of any book in the world. Those who are interested in hot-beds, cold-frames, cold-greenhouses, hot-houses or glass structures of any kind for the growth of plants, can not afford to be without the book.

	Handbook for Lumbermen.....	10
10	Household Conveniences.....	1 40

2	How to Propagate and Grow Fruit, Green*	15
2	Injurious Insects, Cook.....	25

10	Irrigation for the Farm, Garden, and Orchard, Stewart**.....	1 40
----	--	------

This book, so far as I am informed, is almost the only work on this matter that is attracting so much interest, especially recently. Being water from springs, brooks, or windmills, to take the place of rain, during our great droughts, is the great problem before us at the present day. The book has 274 pages and 142 cuts.

5	Manures; How to Make and How to Use them; in paper covers.....	45
---	--	----

6	The same in cloth covers.....	65
---	-------------------------------	----

Covering the whole matter, and discussing every thing to be found on the farm, refuse from factories, mineral fertilizers from mines, etc. It is a complete summing-up of the whole matter. It is written by F. W. Semper.

7	Market-gardening and Farm Notes, by Burnett Landreth.....	90
---	---	----

The Landreth's are the pioneer seedsmen of America; and the book is worth fully as much as we might expect it to be. I think I received hints from it worth the price, before it had been in my hands fifteen minutes. It is exceedingly practical, and tells what has been done and what is BEING done, more than it discourses on theory.

3	Maple Sugar and the Sugar-bush*.....	35
---	--------------------------------------	----

By Prof. A. J. Cook. This was written in the spring of 1887 at my request. As the author has, perhaps, one of the finest sugar-camps in the United States, as well as being an enthusiastic lover of all farm industries, he is better fitted, perhaps, to handle the subject than any other man. The book is written in French, Cuckoo-style, combining wholesome moral lessons with the latest and best method of managing to get the finest syrup and maple sugar, with the least possible expenditure of cash and labor. Everybody who makes sugar or molasses wants the sugar-book. It has 42 pages and 35 cuts.

1	Our Farming, by T. B. Terry**.....	\$2.00
---	------------------------------------	--------

In which he tells "how we have made a run-down farm bring both profit and pleasure."

3	Onions for Profit**.....	45
---	--------------------------	----

Fully up to the times, and includes both the old onion culture and the new method. The book is fully illustrated, and written with the enthusiasm and energy of the author. I estimate its author, T. Greiner. Even if one is not particularly interested in the business, almost any person who picks up Greiner's books will like to read them through.

1	Poultry for Pleasure and Profit**.....	10
---	--	----

11	Practical Floriculture, Henderson*.....	1 35
----	---	------

10	Profits in Poultry*.....	90
----	--------------------------	----

2	Practical Turkey-raising.....	10
---	-------------------------------	----

By Fanny Field. This is a 25-cent book which we offer for 10 cts.; postage, 2 cts.

4	Peabody's Webster's Dictionary.....	10
---	-------------------------------------	----

2	Rats; How to Rid Farms and Buildings of them, as well as other Pests of like Character.....	15
---	---	----

This little book ought to be worth dollars instead of the few cents it costs to any one who has ever been troubled with these pests, and who has not! It is written in such a happy vein that every member of the family will read it clear through, just about as soon as they get hold of it. It contains a complete summing-up of the best information the world can furnish.

1	Silk and the Silkworm.....	10
---	----------------------------	----

10	Small-Fruit Culture, Fuller.....	1 40
----	----------------------------------	------

10	Success in Market-Gardening*.....	90
----	-----------------------------------	----

This is a new book by a real, live, enterprising and successful market-gardener who lives in Arlington, a suburb of Boston, Mass. Friend Rawson has been one of the foremost to make irrigation a practical success, and he now irrigates his grounds by means of a windmill and steam-engine whenever a drought threatens to injure the crops. The book has 208 pages, and is nicely illustrated with 110 engravings.

	Ten Acres Enough.....	1 00
--	-----------------------	------

	Talks on Manures*.....	1 75
--	------------------------	------

This book, by Joseph Harris is, perhaps, the most comprehensive one we have on the subject, and the whole matter is considered by an able writer. It contains 366 pages.

2	The Carpenter's Steel Square and its Uses.....	15
---	--	----

10	The New Agriculture; or, the Waters Led Captive.....	75
----	--	----

2	Treatise on the Horse and his Diseases.....	10
---	---	----

5	Tile Drainage, by W. I. Chamberlain.....	35
---	--	----

Fully illustrated, containing every thing of importance clear up to the present date.

5	Tomato Culture.....	35
---	---------------------	----

In three parts. Part first, by J. W. Day, of Crystal Springs, Miss., treats of tomato culture in the South, with some remarks by A. I. Root, adapting it to the North. Part second—By D. Cunningham, of Connecticut, O., treats of tomato culture especially for canning-factories. Part third—By A. I. Root, treats of plant-growing for market, and high-pressure gardening in general. This little book is interesting because it is one of the first rural books to come from our friends in the South.

3	Winter Care of Horses and Cattle.....	35
---	---------------------------------------	----

This is friend Terry's second book in regard to farm matters; but it is in no wise connected with his other book that it reads almost like a sequel to it. If you have only a horse or a cow, I think it will pay you to invest in the book. It has 44 pages and 4 cuts.

3	Wood's Common Objects of the Microscope**.....	47
---	--	----

8	What to Do and How to be Happy While Doing It, by A. I. Root.....	50
---	---	----

THE A. I. ROOT CO., MEDINA, O.

QUEENS

Promptness is What Counts.

Honey-jars, Shipping-cases, and every thing that bee-keepers use. Root's Goods at Root's Prices, and the Best Shipping-point in the Country. Dealers in Honey and Beeswax. Catalog free.

WALTER S. POWDER,
162 Massachusetts Ave., Indianapolis, Ind.

IF YOU WANT BEES

That will just "roll" in the honey, try Moore's Strain of Italians, the result of 16 years' careful breeding.

Dr. H. B. Lung, Harrodsburg, Ky., says: "I have had the pleasure of seeing many fine strains of bees, yet I have never seen such industrious, energetic bees. I must express my admiration for your success as a bee-propagator."

Reduced Prices: Warranted queens, 70c; 3 for \$1.95; 1 doz., \$7.00. Untested, 60c; 10 or more, 50c each. Select Warranted, 90c; Select Untested, 80c; Tested, \$1.00. Select Tested Breeders, \$1.50 each.

Those who have never dealt with me, I refer to A. I. Root, who has purchased of me 808 queens. Catalog free.

J. P. MOORE, Morgan, Pendleton Co., Ky.

Advantages of Bee-Escapes.

No sweat steals down the heated cheeks and aching back of the bee-keeper as the result of standing in the hot sun puffing, blowing, smoking, and brushing bees; no time is wasted in these disagreeable operations; and no stings received in resentment of such treatment; the honey is secured free from black or even the taint of smoke; the cappings are not injured by the gnawings of bees; and robbers stand no show whatever. If there are any broken burr-combs they are cleaned up by the bees inside the hive, before the honey is removed. **Leading Bee-keepers use the Porter Escape**, and say that without a trial it is impossible to realize the amount of vexatious, annoying, disagreeable work that it saves. The cost is only 20 cts. each, or \$2.25 per doz. As in the past, this escape is manufactured by the Porters, but The A. I. Root Co. has secured control of the sale for this country. Order of your dealer or of

THE A. I. ROOT CO., Medina, Ohio.

"The Southland Queen."

Send \$1.00 for the Southland Queen. Edited by the Atchley family. Plain, practical, and all fresh bee matter. Jennie Atchley is now conducting a bee-keeping school, that began in the June number. You can get back numbers.

A steam bee-hive factory; Root's goods; Dadant's foundation.

We have a fine lot of tested and untested queens for fall trade: Tested, \$1.50 each; untested, 75 cts. each, \$4.25 for six, or \$8.00 per dozen. Send for free catalog that tells all about queen-rearing, and sample journal.

THE JENNIE ATCHLEY CO.,
Beeville, Bee Co., Texas.

W. O. Victor, of Wharton, Tex., took

45,000 Lbs. of Honey in 1894.

He offers Italian Queens—good, old-style honey-queens—untested, first order, to any address, at 50c each. Also bees in any quantity; 450 colonies to draw from. **Root's goods constantly in stock.** Prices to suit the times. Buy near home, and save freight.

«MONEY-MAKERS»

Are a strain of business Italians that winter in the cold North, and are ready for business, with a bushel of bees, when the flowers bloom. They are gentle and industrious. Queens, warranted pure, in June. Each, \$1.00; six, \$5.00; doz., \$9.00. Safe arrival and satisfaction guaranteed. Never had any disease.

Address E. F. QUIGLEY, UNIONVILLE, MO.

Read what J. I. PARENT, of CHARLTON, N. Y., says—"We cut with one of your Combined Machines last winter 50 chaff hives with 7-inch cap, 100 honey-racks, 500 broad frames, 2,000 honey-boxes, and a great deal of other work. This winter we have doubled the amount of bee-hives, etc., to make, and we expect to do it all with this saw. It will do all you say it will."

PLAYING HOG.

Our agents have been accused of gobbling up the best trade in a very hogghish way. Recently they imitated the animal in a still more realistic manner. One 176 lb. agent declared he could crawl through any wire fence where stags are not nearer than 21-2 ft. This statement published in our monthly paper has been going around and many stags are made and won by "Pawmen" in all parts of the country, much to the annoyance of owners of wide-mouthed fences.

HONEY COLUMN.

CITY MARKETS.

DETROIT.—Honey.—Best white comb honey in fair demand at 13¢@14; no dark offered. Extracted, 6¢@7. Beeswax, 23¢@24. M. H. HUNT, Bell Branch, Mich. Sept. 20.

KANSAS CITY.—Honey.—The demand and supply of honey light. We quote white comb, 14; dark, 11; extracted, 4½¢@7. No demand for beeswax, supply light. Price 22¢ HAMBLIN & BEARSS, Kansas City, Mo. Sept. 19.

BOSTON.—Honey.—We quote No. 1 white, comb, 15¢@16, for northern stock; California comb, No. 1, 13¢. California extracted, 5¢@6. Good supply and demand. E. E. BLAKE & Co., Boston, Mass. Sept. 18.

DENVER.—Honey.—Since our last report there has not been much change in our honey market. The shipments we have received run below those of previous years in quality. We quote No. 1 comb in 1-lb. sections, suitable for our cartons, 10¢@11. Extracted, No. 1 white, in 60-lb. cans, two in a case, 6¢@7. Beeswax, 20¢@25. R. K. & J. C. FRISBEE, Denver, Col. Sept. 21.

PHILADELPHIA.—Honey.—Honey is moving off very lively. The demand for comb and extracted is a little earlier this year than usual. We find it harder than usual to sell dark comb, but good to fancy sells quick. We quote comb, 8½¢@14. Extracted, 5¢@5½. Beeswax, 25¢. WM. A. SELSER, No. 10 Vine St., Philadelphia, Pa. Sept. 20.

CHICAGO.—Honey.—We are obtaining 15¢@16 for strictly fancy white comb honey. Good to No. 1, 13¢@14; dark grades, 9¢@12. Extracted, 4½¢@7, according to quality, flavor, color, and package. Beeswax in very good demand at 28¢@30. R. A. BURNETT & Co., 163 So. Water St., Chicago, Ill. Sept. 18.

CHICAGO.—Honey.—We quote fancy white 1-lb. comb honey, retail, 15; wholesale, 14; second grade, 13; amber, 11¢@12. With colder weather and fruits out of the market, we look for a good demand for honey, as maple sugar and maple syrup are very high and scarce. Extracted, 5½¢@6½, depending on quality and package. Beeswax, 30¢. S. T. FISH & Co., 189 South Water St., Chicago, Ill. Sept. 25.

BUFFALO.—Honey.—We quote fancy honey, 15¢@16, with the receipts light; choice, 13¢@14; buckwheat moving slowly at 9¢@10; very good demand for beeswax at 3¢—would be pleased to hear from parties who have some. Extracted dull, and do not advise shipments. BATTERSON & Co., Buffalo, N. Y. Sept. 28.

ALBANY.—Honey.—We believe both receipts and sales of comb honey have been in excess of last season up to this time; but the stock has been for the most part second-grade clover and buckwheat, which would indicate that the crop of fancy white is very short. Buckwheat ample, and of fine quality. We quote No. 1 white, 14¢@15; No. 2, 11¢@12; buckwheat and mixed, 10¢@11. Not much demand yet for extracted except white clover and amber for bottling. CHAS. MCCULLOCH & Co., Albany, N. Y. Aug. 20.

NEW YORK.—Honey.—The market for comb and extracted honey is now open. Comb honey is not arriving as freely as expected, presumably on account of the prolonged heat, but is selling very well considering the hot weather we have had this time of the year. There is quite a supply of extracted on the market. Demand fair for California and Southern honey. We quote fancy comb, 1-lb., 15; fancy 2-lb., 14¢@15; 1-lb. white, 13¢@14; fancy 2-lb., 12¢@13; 1-lb. fair, 11¢@12; fancy, 2-lb., 10¢@11; buckwheat, 1-lb., 10¢@11; 2-lb., 8¢@9. Extracted clover honey, 6¢@7; buckwheat, 5¢@5½; southern, 5¢@6¢ per gal. Demand for beeswax fair, and stock limited. Average stock, 27¢@28; fancy yellow, 29¢. CHAS. ISRAEL & SON, 486 490 Canal St., New York. Sept. 23.

CINCINNATI.—Honey.—Demand is lively for new extracted and comb honey. Arrivals are fair, but insufficient for the demand. Comb honey brings 12¢@16 for choice white. Extracted, 4¢@7. Demand is good for beeswax at 20¢@21 for good to choice yellow. CHAS. F. MUTH & SON, Cincinnati, O. Sept. 18.

FOR SALE.—Choice extracted honey. ELIAS FOX, Hillsboro, Wis.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7¢. Same, partly from cleome (tinted), 6¢. Samples, 8¢. OLIVER FOSTER, Las Animas, Col. eift

FOR SALE.—White comb honey, 14 and 16c, on board cars. G. R. ROUTZAHN, Menallen, Pa.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½¢ in 1000-lb. lots or more. Less than 1000 lbs. at 5¢ in five-gallon cans. Car lots a specialty. J. P. IVY, Secretary Bee-keepers' Association, Phoenix, Maricopa Co., Arizona.

WANTED.—To buy quantity lots of fancy comb honey. Also to sell water-white extracted honey in 60-lb. cans. B. WALKER, Evart, Mich.

FOR SALE.—Buckwheat and amber extracted honey in half-barrels, about 150 lbs. each; well ripened. Prices on application. J. I. PARENT, Birtchton, Saratoga Co., N. Y. eift

FOR SALE.—1200 lbs. of honey, in 60-lb. square cans, 6½ cts. per lb., f.o.b. cars here. Sample by mail. R. H. BAILEY, Ausable Fork, Essex Co., N. Y. 195t

FOR SALE.—We have 14,000 lbs. of choice white extracted honey, in barrels of about 400 lbs., at 6 cts. per lb., f.o.b. cars at apiary. Sample via mailed for 8 cts. in stamps. THE CROSBY CO., San Mateo, Fla.

TRY US. We sell your Poultry, Veals, Fruits and all produce at highest prices. DAILY RETURNS. For stencils, prices and references, write F. I. SAGE & SONS, 183 Reade St., N. Y.

BEESEXWAX WANTED.

Our present stock of beeswax is not large, and we invite shipments from bee-keepers having any to offer. In order to turn more of it our way we will pay, till further notice, 24¢ cash, 26¢ trade, for average wax delivered here; 1 to 2¢ per lb. extra for choice yellow sun-extracted wax. Please note, also, that we are making special prices, below catalog quotations, on comb foundation ordered this fall.

COMB HONEY.

Our supply of comb honey is exhausted. We have some offers, and may have a supply within a few days. We should be pleased to hear from those not too far away who are seeking a market. We have an opening in Cleveland for several thousand pounds of choice honey in 1-lb. sections. The price is not as strong as we wish it were in the interests of bee-keepers. The Cleveland market brings 14 to 16 cents for best grades, less freights and commissions.

EXTRACTED HONEY.

We have a good supply of choice extracted honey in 60-lb. cans. We have both the California white sage and clover and basswood; also some very fine white honey, of a mild and pleasant flavor, from Michigan. Early in the season the Michigan bee-keepers were feeling discouraged at the outlook; but many of them have secured a good crop of very fine honey, gathered mainly in July and August, from something not generally known as a honey-plant. We should be glad to know more of the source of this crop of honey. Our prices are 8¢ per lb. by the case of 2 cans, for any of the above-named varieties. Large lots, at special prices, quoted to those interested.

AUGITE STOVE-MATS.

Although we have not been saying much about these mats lately they have not lost one whit of their virtue. The man who has failed as yet to supply his wife or cook with one of them ought to be ashamed of himself. Those who use them say they would not be without them because of their great advantage in cooking; and to think that any cook should be obliged to get along without one when the best one made, the original augite, can be obtained for 5 cents each, 50 cents per doz., or \$5.00 per gross; by mail 5¢ each, 50¢ per doz. extra. If you can not afford these prices you can still get the mat free. We are determined to get them into the homes of all our readers and their

friends, so far as we are able, and are willing to go more than half way. Send in your renewal to GLEANINGS before the time paid for is up, and we will mail you a mat free; or secure a new subscriber to GLEANINGS and send it with \$1.00 and we will send you 2 mats, or one to you and one to the subscriber, as you may direct; and please notice, all new subscriptions received before Jan. 1, 1896, will receive the paper from the time the subscription is received till Jan. 1, 1897—that is, 15 months if sent right away. This is in addition to any premium that we may offer; but remember, if we offer more than one premium you must choose between them. You are not entitled to several unless it is plainly so stated in the offer. Now, we want to see our pile of thirty gross of mats speedily reduced; and that we shall have to get more to supply the demand.

Wants or Exchange Department.

Notices will be inserted under this head at one half our usual rates. All advertisements intended for this department must not exceed five lines, and you must say you want your ad in this department, or we will not be responsible for errors. You can have the notice as many lines as you please, but all over five lines will cost you according to our regular rates. This department is intended only for bona fide exchanges. Exchange to cash or for price lists, or notices offering articles for sale, can not be inserted under this head. For such our regular rates of 20¢ts. a line will be charged, and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

WANTED.—To exchange several good safety bicycles. Honey wanted. Send sample.
J. A. GREEN, Ottawa, Ill.

WANTED.—To exchange 26-in. planer, power scroll saw, all iron; tenoner, and mortiser, for portable sawmill, or other wood-working machinery. Will give a bargain for cash.
GEO. RALL, Frenchville, Tremp. Co., Wis.

WANTED.—To exchange foundation-mills and honey-extractors for honey or wax.
I. J. STRINGHAM, 405 Park Place, New York.

WANTED.—To exchange 200 colonies of bees for anything useful on plantation.
ANTHONY OPP, Helena, Ark.

WANTED.—To exchange pure bred short-horn cattle, either cows or bulls, for clover or basswood honey. If you want good cattle, write me for prices.
CALVIN LOVETT, Otsego, Mich.

WANTED.—To exchange 2 female fox hounds in whelp; also violin, organ, bone-mill, and set of butcher tools, for any thing useful.
ELIAS FOX, Hillsboro, Wis.

WANTED.—First-class young man to sell honey and celery throughout city of Kingston, 23,000 inhabitants.
AARON SNYDER, Kingston, N. Y.

WANTED.—To exchange 28-inch pneumatic, for lady or gent; also a lot of fine young queens for honey or offers.
CHAS. H. THIES, Steelville, Ill.

WANTED.—To exchange English Beagle hounds, both sexes, old or young, choice bred, for modern fire-arms or offers.
D. S. HALL, South Cabot, Vt.

WANTED.—To exchange raspberry and blackberry plants, \$5.00 per M., for currant-plants.
A. F. LAWRENCE, Hickory Corners, Mich.

WANTED.—Any one having postage-stamps to exchange or a collection to sell, to write at once. Would like to hear from all collectors.
A. E. COLE, Plainfield, N. J.

WANTED.—To purchase swarms of live bees.
LLOYD BROS., Cincinnati, Ohio.

WANTED.—To exchange 10 colonies Italian bees. What have you to trade?
CASSIUS PROVINCE, Masontown, Pa.

Prices Reduced.

The time of the year has come when nuclei should be united, and I wish the queens that I have on hand to move off as rapidly as possible, hence I will sell a single queen for ninety cents, or three for \$2.00. Remember that they are strictly first-class, tested queens, and that they will be sent by return mail as long as they last, and when they are gone I will stop my advertising. REVIEW one year and one queen for \$1.50. REVIEW and the 50-cent book, *Advanced Bee Culture*, for \$1.25. The REVIEW, book, and queen for \$2.00.

W. Z. HUTCHINSON, Flint, Michigan.

THE TORONTO CONVENTION REPORT FREE!

A Full Report of the Proceedings of the North American convention held at Toronto, Canada, will appear in the *weekly American Bee Journal* immediately after the meeting, Sept. 4, 5, and 6. The first installment will be in the number for Sept. 19. If not now a subscriber, you can have that Report free by sending \$1.00 now for the *American Bee Journal* for 1896, as we will "throw in" the balance of the year 1895, beginning with Sept. 19, to new subscribers. Think of it! over 15 months (or nearly 70 numbers) of the old *American Bee Journal* for only \$1.00! Sample copy of *Bee Journal* free.

And, besides all that, each new subscriber will receive a free copy of the 160-page book, "Bees and Honey." Better send on your dollar at once, and join the procession. Mention this paper, please.

GEO. W. YORK & CO., 56 Fifth Avenue, Chicago, Ill.

Proof Beyond Doubt.

A customer, looking over my 400 hives in home apiary, said, "Where are your bees? Mine were flying all around thick this morning." I said, "Just stop; look down at any hive." He was amazed. They were just pouring in thick with their heavy loads. This proves two things—they can't be excelled as workers, and quiet.

I opened several hives. He had no veil; was in the apiary $\frac{1}{2}$ of an hour; was not bothered once. Try them. Untested guaranteed queens, 75c. Send for whole sale price list.

Wm. A. Selser,
Wyncote, Pa.

Headquarters in Missouri For Root's Goods.

Can supply you with all the fixtures used in an apiary. Best goods at lowest prices. Catalog free.
JNO. NEBEL & SON, High Hill, Mo.

Belgian Hares! No better in America. Breeders, \$4 a pair; young, \$2. Heavy stock. First-prize buck. Stamp.
W. W. KULP, Pottstown, Pa.

World's Fair Medal

Awarded my *Foundation*. Send for free samples. Dealers, write for wholesale prices. Root's new *Polished Sections* and other goods at his prices. Free Illustrated Price List of every thing needed in the apiary.
Bell Branch, Mich. M. H. Hunt.

SECTIONS, BEE-HIVES, SHIPPING-CASES

We make a specialty of these goods, and defy competition in quality, workmanship, and prices.

Write for free, illustrated catalog and price list.

No. 20.

STRAY STRAWS

FROM DR. C. C. MILLER.

IF YOU MUST FEED, better rush it.

SOMNAMBULIST, in *Progressive*, seems to be warmly drawn toward mustard as a honey-plant. But mustard often draws warmly.

SECTIONS that are extracted, to be used another year, must be cleaned out *by the bees*, or your sections will be likely to contain candied honey.

AUSTRALIANS are giving attention to the question whether it may not be feasible and profitable to so manage as to increase the production of wax.

"ONCE OR TWICE, when I was not present, somebody said there was a little jangle," says A. I. Root. p. 713, which goes to show he ought to have known better than to be absent from the convention.

THAT VANILLA FLAVOR hardly came from poppies, as hinted on page 704, for I had the same-flavored honey a year or two ago, and there are no poppies here. [Can you guess what it did come from then?—Ed.]

APIS DORSATA. The editor of *Review* ears that the introduction of the big Indian bee might be like that of the English sparrow, the new bee living wild and using the nectar that our hive bees need.

HENS' EGGS were put in a colony of bees for hatching, by Mr. Schornack. In a week the eggs had started to hatch, but none ever produced chickens.—*Centralblatt*. [Why didn't you give your rotten-egg experience along the same line?—Ed.]

THE CROCK-AND-PLATE feeder is as good as the Miller feeder, except when you want to feed more than the crock will hold at one time. [Fill the crock once or twice more as the case may warrant. That's the way we do.—Ed.]

A PICTURE of alfalfa is hardly needed for those who are familiar with sweet clover. Just look for a plant with sweet-clover leaves and

purple blossoms. [That's good; but will the Western bee-keeper agree as to this similarity?—Ed.]

SEVERAL CASES of foul brood broke out at the Michigan Experiment Apiary this season, in colonies that were diseased years ago, but healthy since. Mr. Taylor thinks the dearth caused the bees this year to eat honey that was stored years ago with foul-brood germs in it.

DID YOU EVER notice how much harder it is to get bees to take feed from a feeder in spring than in the fall? It might pay to put a story of empty combs over an excluder in the fall, and feed enough to have them filled, just to have them ready for the next spring. I'm trying it.

IF THE INTEREST among bee-keepers continues in such forage-plants as crimson clover, sweet clover, alfalfa, *lathyrus sylvestris*, etc., the tables will be turned; and instead of agricultural journals with a bee department there will be bee-journals with an agricultural department.

SOMNAMBULIST complains in *Progressive*, in a not very sleepy way, of the Ohio law that makes sweet clover a noxious weed, to harbor which is a crime, and wants me to go as a missionary to labor with the heathen legislators of Ohio. Messrs. Boardman and Root are the men for that job.

HASTY, in *Review*, suspects that not more than half the eggs laid by a queen are hatched. I suspect, Hasty, that your suspicion is not above suspicion. [A good many things seem to point that way, that's sure. We ought to have more light on this point. Nudge experimenter Taylor's elbow.—Ed.]

A HASTY VISIT the other day to the small-fruit farm of H. R. Cotta, Freeport, Ill., made me almost wish I could give up bees and go into small fruits. I wish A. I. Root had been along to see the fine shape in which every thing was kept; \$400 an acre from Ancient Briton blackberries!

THE EDITOR of *Review* says he no longer looks to see if a young queen gets to laying all right, philosophizing thus: "Suppose a queen is lost,

the hive, combs, and honey are left, and there is a better chance in the field for the other bees." I've known cases in which neither combs nor honey was left. [My experience seems to show that it does pay every time to see whether a young queen actually turns out to be fertile and a good one. Too many queens turn up missing to make such a policy as Bro. Hutchinson indicates a safe and profitable one, in our yards at least.—ED.]

I'M THANKFUL, very thankful, to say of my bees, that lately "a change has come over the spirit of their dreams," and they've stopped dreaming, gone to work, and are now filled up heavy for winter. Who knows but some of these years they may conclude to work again during the clover harvest?

ONE ADVANTAGE of using percolating feeders, or the crock-and-plate method, is that robbers don't trouble as they do when you use syrup. When you pour in the sugar, robbers don't care for dry sugar. □ When you pour in the water, it stays on top, and robbers don't hanker after cold water. [Yes, and that advantage is a big one in a beginner's case.—ED.]

ALFALFA is the same thing as lucerne or luzerne. Formerly it was known in this country by its French name, "lucerne;" but in 1853 it was introduced into California from Chili, and has since been known by its Spanish name, "alfalfa." It is also called Chilian clover and Brazilian clover. Its botanical name is *Medicago sativa*.

F. A. LOCKHART has mailed me a cage with equal numbers of Carniolans and blacks. The one lot are nearly solid black, and compared with them the Carniolans are regular zebras, striped alternately gray and black, above and below; no trouble to distinguish them, and no trouble to describe the difference. □ [No, not if the other fellow has seen the difference.—ED.]

INTRODUCING QUEENS. Here's the plan N. D. West gives in *Canadian Bee Journal*. Remove the condemned queen, and then, before closing the hive, give them a queen in West's spiral-wire queen-cage, with a piece of hard candy $1\frac{1}{2}$ inches long in the large end of the cage (use store candy). Then place the cage in the hive on the top of the frames, or between the combs, and in from 30 to 48 hours the queen will be liberated.

FOUL BROOD being discussed at a convention reported in the *Australian Bee Bulletin*, a number claimed that the introduction of Italians made it easier to prevent and cure the disease. Isn't that a new claim for the yellow favorites? [Yes. It has been urged by a few that our native blacks are much more hardy and more proof against disease; but real facts here from careful unprejudiced observers, I think, show that there is no real difference.—ED.]

THE BEE-KEEPERS' UNION.

MUCH NEEDED AND IMPORTANT WORK FOR IT TO DO; ADULTERATION IN CALIFORNIA; THE TRUTH OF AN "ESTIMATE" QUESTIONED.

By C. W. Dayton.

The amalgamation of the N. A. B. K. A. and B. K. U. might turn out like uniting two colonies of bees—in a little time the united colony is no stronger than the single one. That there is need of a more powerful organization of bee-keepers, I do not hesitate to declare. What is meant by "powerful" relates more directly to the fatness of the treasury. An exhaustless treasury and an active executive constitute just such a team as we want. The present executive force would be very hard to improve; but if bee-keepers would rally for the protection of their interests only slightly there might be \$50,000 in the treasury. I will mention some of the purposes for which such money might be used.

First, there are some counties in this State where the keeping of bees is prohibited. Such laws were made on account of the supposed harm which bees do to grapes. At that time there were thousands of acres of vineyards. A disease has since destroyed the grapevines, and the wineries are dilapidated and fallen down. But the laws against the bees still remain. Some of the worst-cut grapes I have ever seen were several miles from an apiary, and at the time of a honey-flow. There were many Mexican hornets, but no honey-bees working upon them. Last year a Los Angeles County supervisor impetuously charged all such depredations to honey-bees. He said that one hive of bees standing at the corner of a vineyard would destroy the grapes for several rods around. A bee-keeper may argue for the bees, and his arguments have no weight, simply because he keeps bees. A vineyardist may charge all the damage to the bees, because he deludedly thinks bee-keeping a lazy man's occupation. We need a union which is able to place three or five disinterested and competent men in the field, and keep them there until the facts are established; then fight the unjust laws until they are reversed. Bee-keeping is one of the useful and pure industries; but it has been stamped into the ground because it happened to come in the way of the wine industry. Next time we may be compelled to move because our bees sip at and get trapped in the emptied beer-kegs standing by the saloon. The bees ought to be ashamed of this; but here in California, water is sometimes very scarce. The wine industry is a positive injury and

nuisance, carrying debauchery and crime in its wake, while bee-keeping brings health and intelligence at every step of its progress. It is not only necessary that the facts be ascertained for bee-keepers, but they should be established by publication and circulation, so that any backwoods ignoramus like the Los Angeles supervisor can not wield a contaminating influence. The more power and execution there is in the organization, the more regard and friendship there is cultivated for the industry itself.

In many cities, especially where the corporate limits include large scopes of farming lands, it is sought to prohibit the keeping of bees. This was the case in Los Angeles, either because the city fathers wanted business to indicate that they merited their present salaries, or because the bees paid an occasional visit to the fruit-stands. I am uncertain which. But I do know there were one thousand flies to one bee; and while flies are filthy, such bees are extremely harmless and cleanly. The fear of an interference by the Bee-keepers' Union permitted the bees to remain.

Another line of occupation for such an organization is the detection and punishment of adulterators. First, there should be laws made to prohibit adulteration. The only way to get them is to put shoulders to the wheel, and push. The ground is smooth, and the axle well oiled, but the push is lacking. Just a bare willingness will almost start the wheel moving. It needs detectives to gather evidence, and lawyers to tell what evidence is. It is estimated that one-half the honey produced by California, has been adulterated with glucose, and sent east, by a few if not by a very few wholesale firms. Honest dealers refused to buy, because eastern markets have been ruined by the hand of the adulterator, and the best of honey now goes begging for 4 cents while there is only a partial crop. Thus the wealthy adulterator's coffers have been filled, and the pockets of the poor bee-keeper are now being emptied, and the eastern honey markets are stagnated to a corresponding extent.

Another imposition upon our welfare is the local retailer or grocer. He is the man who makes a living by constantly beating down all prices but his own. He tells the honey-man there is a big crop when it is very small. He tells the honey-man that his honey is of poor quality. Then when he sells it out he tells his customers how fine the quality is; docks two cents for propolis on sections, but sells it out as if there never was any such thing as propolis; pays 4 cents a pound for extracted honey, which he sells at 8 or 10, while he pays \$5.50 per 100 pounds for sugar which he sells out at 19 pounds for one dollar, or $\frac{1}{4}$ cent per pound less than the purchase price. One is a local, neighborly industry, while the other is Spreckles'

monopoly, of the Sandwich Islands. If the grocer will charge as much for selling sugar as honey, it will be eight pounds for \$1.00. This will check the consumer's greediness for that foreign monopolistic commodity in favor of what may be obtained near home. That will make honey 10 cents in place of 4.

Still another complaint I have to make is in regard to the imposition of licenses upon those who peddle their own productions, by county supervisors and town councils. At the bottom of this will doubtless be found the merchants, in the endeavor to swing the retail business into their exclusive hands. Fruit, tinware, or notions is different from honey, because they can not be, or are not liable to be, adulterated. I believe that nine-tenths of the honey adulteration of the past was the work of dealers. Not only city dealers, but several country merchants, have boasted of how they did it. With their high profits on honey, and no profits on sugar, and their adulterating tendencies, are we going to submit without a murmur to their sitting down upon our humble vocation with a license? Such a law is a step in favor of capital and monopoly, both great and small.

Florence, Cal., Sept. 10.

[I think you are quite right as to fields of work for the Union. I have, as you may know, advocated that it was high time for it to branch out, and one of these lines of work was the hiring of detectives to follow up suspected cases of adulteration, and not wait for outside sources to bring in a mountain of evidence, for such evidence will not usually come in of itself. But it seems to me the estimate is rather sweeping, that assumes that "one-half the honey produced by California has been adulterated with glucose." I don't believe it. While I do not call in question your veracity, I should like to know the source or basis upon which such estimate is made, or the person or persons making it, before I could swallow it. You see, if it is not true, or is based on insufficient data or poor authority, the mere reference to it in print, *unchallenged*, does harm. Suppose, for instance, that the newspapers all over the land pass the statement the rounds, that half of all the so-called California honey is adulterated, and then back it up by saying that California bee-keepers generally believe it, what will be the effect on consumers? If such a thing is *not* true, a fearful damage will be done to California bee-keeping interests. Now, then, GLEANINGS wishes to be enlightened on this "estimate." Let it be sifted to the bottom; and if it is true, we will, with the help of the Union, try to remove the condition that makes such a statement true.—ED.]

CALIFORNIA ECHOES.

By Rambler.

"The pleasant occupation of tending bees," says Bro. Hutchinson, in the *Cosmopolitan*. Are we to be considered as bee-tenders, instead of bee-keepers after this?

What a fuss you benedicts make over the mere suggestion of crackers and cheese! I

should like to see your antics if you had to roll up in a blanket and sleep in the shelter of some friendly rock. Still, some very well-regulated people find health and pleasure in so doing in this country.

That was an unfair proceeding on the part of Bro. Schaeffle, in relation to smiling Betsy. He withheld a very important item. Those natives have a superstition that, if they allow their photos to be taken, they will not live long. Poor smiling Betsy, after the camera episode, went into decline, and died in about six weeks. *Vale* Betsey.

Cyprian bees are at a discount in this portion of the State. Their vindictive nature and the swarming impulse are undesirable qualities to the majority of bee-keepers. Mr. D. A. Wheeler, of Riverside, having several hundred colonies of this race, has resolved to queen his apiaries. Mr. F. A. Lockhart, of Lake George, N. Y., is filling an order on this job for 300 queens, Italian and Carniolans. Cyprians must go.

I do not consider that McIntyre-Holly test a fair one; for a hive with loose frames, and seven inches deep, can not be considered a Heddon principle at all; and if Mr. Holley is satisfied with the test, I think an important portion of his education in relation to the Heddon hive was neglected. With a frame 5% deep, with proper spaces, I have found a prolific queen ready to occupy three chambers. But I will say nothing further upon this vexed question. I suppose, in spite of all I may say, these friends will persist in sticking to their jumbo barrel.

A lawyer, reared in the backwoods, as the story goes, began to rise in his profession, and his increasing circle of friends found that he used a common flour-barrel in which to store his documents, letters, etc. If a document was needed he would plunge his hand into the barrel, and seldom failed to bring forth the right paper. His well-meaning friends made him a present of a new up-to-date secretary, with an adequate supply of pigeon-holes. The documents were transferred from the barrel to the new-fangled thing; but it was not adapted to the man, and he soon returned to the use of the barrel again. It strikes me that this is the reason why Bro. B. Taylor failed with the divisible-brood-chamber hive.

On page 642, under "market gardening," the pit, or vault, under water-closets, is condemned, and justly. But here is a point that I have observed that is not mentioned. Many such pits in some of our lively towns here in California, and probably elsewhere, are subject to being flushed with water during the irrigation of land near by. A period of several weeks elapses before more water is turned in, and between times the water becomes stagnant, and a

breeding-place for millions of mosquitoes. Then people go around wondering where all the mosquitoes come from; put up screens, burn buhach, and make a great fuss. It all comes from that nasty pit; and if it must be used, the throwing in of a little chloride of lime occasionally would cure the mosquito nuisance if not the stench.

THE SIZE OF HIVES.

THE RELATIVE ADVANTAGES OF LARGE AND SMALL SIZES DISCUSSED FURTHER

By Miss Emma Wilson.

The hive question bothers me a great deal. I am like the boy who wanted to eat his cake and keep it too. I don't want to give up the eight-frame hive, it is so nice to handle, and such a comfort when hauling-time comes. And yet—and yet—I fear it is not big enough. In fact, I feel certain it is not, take it all the year round.

And now comes in the point Dr. Miller and I do not agree upon. I very much object to tiering up. Lifting off and on upper stories is too hard work. I very much prefer having all my frames in one story. He rather favors holding on to the eight-frame size, and giving extra stories when needed. I think that would be a good plan too, as our queens go readily from one story to the other, even if it were not for the great amount of hard lifting that is involved in it. Just think a minute about it. For every colony that is examined, that upper story has to be lifted off and then lifted back again, and the upper story is always the heavier one. After you have lifted off and on upper stories all day, you begin to think there is not much enjoyment in bee-keeping.

Another point in favor of one story is, I think I can find queens a little quicker with one story than with two. With two stories she has a little more chance to get out of your way.

Then the matter of wintering comes in for consideration. With the eight-frame hive there is always a little uncertainty as to whether they will have stores enough or not. In fact, you may feel pretty certain that most of the strong colonies will need feeding either fall or spring. With a larger hive there will be chance for extra frames of honey, to be used if needed, and I do believe that bees do just a little better in spring if they have an abundance of stores.

I feel very sure that we've had more swarming with the eight-frame hive than we used to have with the ten-frame hive. I don't know whether the smaller hive is entirely to blame for it or not. I don't have as much faith that plenty of room will prevent swarming as I used to have. It may help, but a good many of our colonies have made preparations for swarming with sixteen frames, and certainly no queen ought to feel badly crowded with that number.

If all our bees were kept at home, and we had

no out-apiaries, I think I should decide very quickly that I want a large hive. With a large hive you can have rousing big colonies, and they are the ones that give you the honey. If at any time you wish to contract down to eight frames, it is easily done. But, oh dear me! I just can't bear to even think of hauling the bees and lifting those great big clumsy hives again. I think that, on the whole, I shall still vote for the eight-frame hives in the out-apiaries, but will vote for a large hive at home.

Marengo, Ill.

□[I think most bee-men who have a liking for the two hives, and would take less account of the lifting item, would vote the other way—large hives for out-apiaries and the smaller ones for the home yard. The former, being less liable to cast swarms, would require less the constant watching of an attendant; but neighbor Vernon Burt, a strapping big fellow, with whom I talked yesterday, would vote as you do. Indeed, his out-yard has the eights run for comb honey, and the home the tens. During swarming-time he spends most of his time at his one out-yard. His mother and brother look after the home bees during his absence. As these colonies are larger, and are run for extracted, they do not require much of their attention. When the swarming-hours are over at the out-yard, Vernon returns home and gives these bees any attention, so far as room is concerned, that they may require. But suppose Mr. Burt had more than one out-yard. I think he would want the eight frames at home and the ten-frames at the out-yards.]

While I am about it, I may remark that friend B. says his ten-frame colonies, when made to occupy the whole set of frames during the *breeding* season, and are then contracted down to eight with a dummy, are just the ones to give more honey than those colonies that have been confined to the eight frame space all through. He would, if he were to start anew, have all ten frames, and these he would reduce, whenever it was to his advantage, to eight, by dummies. Here is one on the other side.—Ed.]

SMALL HIVES AHEAD IN HONEY; THREE MONTHS' HONEY-FLOW.

I see in GLEANINGS, Aug. 1, that Dr. C. C. Miller thinks it wouldn't make any difference what kind of hive he had if he could have a steady flow of honey for three months. When I send in my report, which I will do as soon as the honey season is over, the doctor will see that, the longer the flow of honey, the more need of having a hive that the bees will continue to store honey in. My bees are doing but very little at present in my large hives, while the small ones are piling in the honey as though they were going to work all winter. I have been careful to put a pencil-mark, with the date, on one of my best hives each time I have extracted.

I have just been and counted the marks, and find that I have taken the honey out 13 times. I looked in the hive and found it full again. I will take it out to-morrow. That will be 14 times this summer.

I have weighed the honey several times, and it would average 22 lbs. each time, amounting

to 308 lbs. I had 20 colonies to start with this spring (8 were small ones); I increased them to 30. I have taken out 3135 lbs. of extracted honey, and about 100 lbs. of comb honey. I don't want any one to think that all my small hives did as well as the one I marked, for they did not; but they all did much better than the large ones.

How would it do to cut the number in the tin tags and dip them in coal tar, or something black, then tack them on to a white hive? I think that would be the cheapest plan.

Bunkersville, Nev., Aug. 19. J. I. EARL.

[Cutting the numbers out in the tags would be much more expensive than putting them on with stencil or printing-press. The cutting would require a set of dies that would cost hundreds of dollars.—Ed.]

HOW BEES WORK ON STRAWBERRY-BLOSSOMS.

AUGER-HOLE ENTRANCES NEAR THE CENTER OF THE HIVE AN ADVANTAGE.

By *Elias Fox.*

I have been a silent listener to the long controversy as to whether or not bees work on strawberry-blossoms. I was indeed surprised to see the fact disputed, and by men who, perhaps, are old enough to be my father, and the difference of opinion is truly amusing. While I was at home on the farm my father kept a few bees, and we invariably raised strawberries; and it was as common to see bees working on the blossoms as to see them on the willow, dandelion, or any other blossoms in their respective seasons. When I left the farm, 13 years ago, I purchased two colonies of bees; and as long as I kept them here it was a common thing to see them working on strawberry-blossoms. After removing them from the village I did not raise any strawberries until the past two seasons. Last year I lost my wife about the time they were in bloom; and this year the sickness and death of my little boy filled my mind and heart with other thoughts, so I could not say positively whether they worked on them or not; but if they did not, it was on account of the atmosphere not being in proper condition for the secretion of nectar. The fact of bees working on white clover is not disputed; yet it is an undisputable fact that we often see fields white with it, and not a bee on it; while other years they will swarm on it as long as it lasts; but as for getting surplus honey from it in this locality, it is a rare thing late years. If the acreage of strawberries were as large as that of white clover, I doubt there being any dispute as to whether or not bees work on them.

I have heard it said a great many times that bees gather honey from corn-tassel; but I claim they do not—at least in this locality.

In regard to friend Miller's Straw, page 584, I would say I have an inch hole in or near the center of all my hives (front), and find it a great advantage, whether the Langstroth or a deeper hive, as the bees use it more in proportion than they do the entrance across the front at the bottom, and it seems to give a more perfect circulation, thereby lessening the liability of combs melting down in extremely hot weather, where no shade is used; at least, I used to be troubled somewhat until I tried this extra entrance, and since then have not had a comb melt; and when a swarm issues, this hole is crowded to its utmost. I may have something to say later on in regard to the 8 and 10 frame hive, and also the controversy concerning yellow bees.

Hillsboro, Wis., Aug. 8

[I should like to hear from you further on the subject indicated in your last sentence. I think we may now consider it fully settled that bees do work on strawberry-blossoms. And here is another that furnishes still further proof.—Ed.]

BEES NECESSARY FOR STRAWBERRY-FRUITING;
INDISPUTABLE PROOF; A HARD RUB
FOR THE CARNIOLANS; JAPANESE
BUCKWHEAT.

As to bees working on strawberry bloom, I would say that they do. I covered my strawberry-beds up with straw during the frosty nights of last spring, and uncovered them in the mornings, and by noon the bees would be fairly swarming on them. They worked on it equal to white or alsike clover. A few years ago I visited an extensive strawberry-grower a few miles from here; and after he showed me around the place I happened to see half a dozen or more hives of bees, and remarked to him, "I see you are a bee-keeper." He said, "Yes, I keep them to fertilize the strawberry bloom." He said that the only time he had failed to get a full crop was one season when it rained so much that the bees were not able to work on the blossoms except an hour or two at a time, and then only on the outside of the matted rows. He did not get any berries at all except where the bees worked. He told me he could calculate almost to a bushel as to how many berries he would get if the weather was fine when they were in blossom.

You will remember that I wrote an article in GLEANINGS a little over five years ago as to the stinging and honey-gathering qualities of the Carniolan bees. The breeder of these queens wrote me a long letter, but requested me not to answer in GLEANINGS, but to try them another year; so I have fooled with them ever since, getting more stings than honey. The first year I gave them ten frames in the brood-chamber; but as the surplus crop was a failure I concluded I would reduce them to eight frames the second season. They all wintered well the first winter; but long before the honey

harvest had arrived they had used up all of their honey, and had to be fed. They were meeker than Moses. I fed them by filling Mason cans with honey diluted with water, tying cheese-cloth over the tops of them, and inverting them over the brood-frames. When cans were empty I would remove cans and give the bees a quick shake in front of the hives to dislodge them; but every last one of them would have its sting fast in the cloth instead of letting go like decent bees. Well, four of them got to swarming, and their swarms swarmed so I got half of my swarms Carniolans. I used their combs for extracting-purposes, after they swarmed, to prevent increase. As to honey, the two that did not swarm did as well the second season as my Italians; but, how they stung when they were swarming! none of the family cared to be out of doors, as they were sure to be stung. No one would care to shake the bees off their combs, as they were afraid of being stung. To stand within ten feet of one of the hives in the fall, and look at them, they would come at you in a steady stream, which meant sure death if you did not make tracks immediately. They would drop on to any one like so many flies, and sting without any warning whatever. The stinging qualities of my bees have been increased over 50 per cent since introducing them.

Is it true that bees gather as much honey from Japanese buckwheat as they do from the gray and silverhull? I have heard farmers say that it hardly amounts to any thing for honey. At the south of me there is a large piece of common buckwheat, while in other directions there is nothing but Japanese. Well, the bees seem to prefer to go south—that is, the bulk of them. Two years nothing was sown but Japanese, and those years I got no honey from buckwheat to speak of. GEO. BROADBENT.

Factoryville, Pa., Aug. 12.

[Yes, Japanese yields as much honey as any other buckwheat, and very much more grain. The cases you mention do not prove any thing against the Japanese. All buckwheats some seasons fail to yield honey, and it is evident that difference in soils even on different farms not far apart makes some difference. Even if the bees do prefer to go "south" it may mean that the character of the ground in that direction is more conducive to nectar secretion.—Ed.]

CRIMSON CLOVER.

ITS BEAUTY AND PRACTICAL VALUE.

By L. Staples.

Crimson clover is an annual, and should be sown in the fall, in August, September, and October. It germinates very quickly, and grows rapidly through the fall and winter, and blossoms about May 1. In this latitude this clover can be sown after other crops have been removed from the ground, and in this way will

be of inestimable value in holding valuable nitrates in the soil that are otherwise washed out of the bare ground. It furnishes fall, winter, and early spring pasture, and enriches and stores up plant-food for next crop. A field of crimson clover in bloom is strikingly beautiful. Its marvelous beauty surpasses any thing ever seen in a field crop. It is good for hay; will yield from two to three tons per acre, and from six to ten bushels of seed. About eight bushels of seed is an average yield. The plant seems to flourish and do well in all soils, in a heavy clay as well as a light sand. Crimson clover makes a good bee-pasture, and every bee-keeper will sow a field of crimson clover as soon as he understands its value as a honey-plant. The seed being cheap, I predict that, when farmers see what this clover will do for them, they will scatter the seed on all vacant ground. Ten and twelve quarts of seed are usually sown on an acre. The ground should be prepared by plowing or cultivating shallow. Pulverize the surface, and cover the seed very lightly.

CRIMSON CLOVER.

Crimson clover is very hardy, and will succeed where the common red clover or wheat does. I think that, where failures are made with this plant, it is caused mostly by sowing imported seed. Always, if possible, obtain American-grown seed that is acclimated to this country, and a hay and seed crop is assured. No other clover remains green all through the winter; no other plant furnishes winter pasture like crimson clover. Every farmer and bee-keeper, and every lady who loves flowers,

should sow at least a small bed of crimson clover this fall.

Grand Rapids, Mich., Sept. 20.

[The cut below, from the *American Bee Journal*, gives another view of this truly remarkable clover. This, compared with our engraving in our Sept. 1st issue, p. 658, will give a good idea of the plant.—Ed.]

BREEDING FOR CERTAIN CHARACTERISTICS.

SOME OF THE PRACTICAL DIFFICULTIES IN THE WAY.

By Dr. C. C. Miller.

I have read with a good deal of interest the article by another of the Miller family, on page 620. He makes the point that we should watch for the individual peculiarities of colonies, and treat them accordingly. There may be something in that; but it isn't so easy of execution, for it may take us the whole of a season, or the greater part of it, to get acquainted with the peculiarities of some colonies; and then, just as we get them learned, a change of queens brings about a radical change in disposition; for with each change of queen, half the blood is likely to be changed by the new queen meeting a drone of different disposition.

May we not, however, take advantage of our acquaintance with individual colonies so far as to select for breeding, so as to perpetuate and establish the traits that best suit us? Alas! again there must be much random work, because we have control of only one parent; and yet by persistent selection something may be accomplished. Here's a colony not as active as others. Instead of letting it requeen itself at swarming, we supply it with a queen from our most active colony. This new queen meets a drone of stock so lazy that there is no perceptible improvement. Still, the resulting workers will not be so bad as they would have been if the mother as well the father had been of bad stock. By continual effort at weeding out the bad and encouraging the good, even if we never pay the slightest attention to the suppressing of drones of bad colonies, in time there will be a change in the character of the drones themselves. Even if we have no direct control of colonies scattered all around us, in time these will feel the influence of our efforts, and we may feel repaid for years of persistent effort at breeding from the best. If we can not give the matter full attention, even occasional efforts will give proportionate rewards. Keep trying, some of the time at least.

HOW LARGE IS IT DESIRABLE TO HAVE COLONIES IN SPRING?

A sentence on p. 628 arrests attention: "Too large a swarm in early spring is not desirable, and never does as well when the harvest comes." Now, I wish Mr. Hand would go a little further and tell us what constitutes too large a colony, and why a colony of a certain size in spring will

not do as well at harvest time as one a little bit smaller. If we know what the best size is, it will be easy to avoid trouble, for there are usually colonies too small that might be strengthened from the overgrown ones; and even if all were too large, it would be an easy matter to destroy the surplus population each spring.

WILL QUEENS KEEP GOING BACK AND FORTH FROM ONE STORY TO ANOTHER?

I continue to be misquoted in GLEANINGS, to the effect that I found queens would not breed properly in two sections of a hive at the same time. I do not remember to have ever said any thing of the kind. Indeed, I have always said that I had no difficulty in that direction, and that my queens went readily of their own accord from one story to another. I think the misunderstanding came from my reporting that, when I confined a queen in an upper story to oblige her to lay there, she utterly refused to do any thing of the kind—quite a different thing from the other.

You may remember that C. A. Hatch said his bees would go from the lower to the upper story, but would not go down again, and I could not understand why mine should act so differently. Afterward I thought it might be that his top and bottom bars were such as to form a barrier across which the queen would not pass, while in my case a space of nearly an inch between the two allowed the bees to fill in a lot of comb in which the queen could lay and then easily pass to the other story.

But the question came up whether my queens would act in the same way with my new frames having top and bottom bars each $1\frac{1}{8}$ inches wide, having respectively a thickness of $\frac{1}{8}$ and $\frac{1}{4}$, thus making, with the $\frac{1}{4}$ inch between them, a space of $1\frac{1}{8}$ inches without any comb, across which the queen must pass to get from one story to the other. Despairing of success without some special means, I studied a good deal upon the matter, and finally made connection between the two stories by means of two dummies of inch stuff, the lower dummy having a $\frac{1}{4}$ section of comb in its upper part, and the upper one having a section in its lower part, one placed in the hive directly over the other, no wood between the combs in the two sections, and a $\frac{1}{4}$ space between them. The bees promptly joined the two sections together, and the queen passed back and forth as I expected.

In order to compare, I tried one colony without this special help, and by some means the queen went in a short time from the upper to the lower story. Then, to give the matter a pretty full test, I put seven colonies on these frames in two stories. The combs were new, the colonies not overly strong, and there was no likelihood that in any case they would occupy more than eight combs. So I put four combs in the upper story and four combs in the lower story, leaving the queen in the upper story. If

I found eggs in the lower story after four or more days, then I would know to a certainty that the queen had gone below.

One colony was so weak that the queen could occupy only about three frames; and as these were all in the upper story, it was not strange she did not go below. Another remained in the upper story without going below, and I feel pretty sure she would have occupied more combs if they had all been in the upper story. As to the rest, however, the queens seemed to occupy one story as well as the other, altogether against my expectation. For instance, Aug. 22 I found, in No. 36, eggs in both stories; and also Aug. 26 I found eggs in both stories. That shows clearly that, during the week of Aug. 19—26, the queen must have made at least three changes from one story to the other. So I feel pretty sure that, as a rule, the queen will occupy two stories about as well as one, if the room in one story is not sufficient.

The question still remains, "Why do Brother Hatch's bees act so differently from mine?" I am wondering if it isn't just possible that his queens had so much room in the upper story that they did not feel the need of going down.

Marengo, Ill.

[Yes, your last sentence probably hits the key to the whole situation. How is it, Bro. Hatch?—ED.]

EUROPEAN MATTERS.

THE FORTIETH CONVENTION AT LEIPZIG: KING ALBERT AND THE BEE-KEEPERS; THE INTERNATIONAL BEE-KEEPERS' CONGRESS AT PARIS; AN 82-CENT FOUNDATION-PRESS IN GERMANY.

By Charles Norman.

On and after the 10th of August, the fortieth convention of the German, Austrian, and Hungarian bee-keepers took place at Leipzig, kingdom of Saxony. As that well-known German bee-master, Mr. Gravenhorst, usually reports to you on these conventions, I restrict myself to a few remarks. There were over 1500 participants present—a number unheard of at our conventions—and the whole affair was a great success. King Albert, of Saxony, who had accepted the protectorate over the convention, made his appearance for an hour or two, and was honored as only monarchs are honored by their humble subjects. He was cheered at and cheered at; he was, wherever he stepped, surrounded by the happy bee-keepers, "like the queen-bee by her bees;" he was "speeched at" by several orators, one of whom even spoke of "us Saxons to whom our king is the star and pride of our life." I wonder what climax this man would have come to had he had to address the highest German monarch, the emperor.

Well, great as the success of the convention was, yet one German reporter says that the German-Austrian reversible honey-extractors

are heavy and clumsy tools, far surpassed by those manufactured in England and the United States; he also says that we Americans exhibit our honey and bee-keepers' supplies in a much better and more systematic way; and, furthermore, he says that our rules for the distribution of prizes and premiums are much more detailed, strict, and specified.

By Mr. Gravenhorst's *Bienenzeitung* I see that at Paris, France, an international bee-keepers' congress was held in July. The German exhibitors are said to have excelled there; and it is quite refreshing, in these times of chauvinism (just think of how the anniversary of the victory of Sedan was celebrated in Germany the other day), that the French bee-keepers treated the German exhibitors and visitors as brethren and friends in the fullest meaning of the word. That hatred and so-called patriotic rivalry which are sown and nourished between the nations by their rulers are an artificial, unnatural, inhuman feeling which exists in minds of criminal turn only.

On the European continent, foundation-mills are much less used than in this country of ours. Very many bee-keepers there make their foundation themselves on hand foundation-presses or forms. Of one of them, Rietsche's, between 6000 and 7000 have been sold. By the *Leipziger Bienenzeitung* I see that another one is manufactured now which consists partly of cement, and is said to furnish thinner foundation than the Rietsche press, and to work faster than the latter, as no brushing off, no rubbing-in of honey and the like, is needed; its price is also much cheaper, being only three and a half reichsmarks, or about 82 cents. Should the press break by falling down, the manufacturer repairs it for a trifle, as the wrought-iron frame, the most valuable part of it, can not break. To use the press it is previously laid in water for at least five to six hours. Before the work is commenced, the table has to be wetted thoroughly, and it must be kept wet as long as the work is going on. Reason why: The press has no rim to collect and gather the wax which is forced out by the manipulation. This wax flows partly down on the table, and partly sticks to the outer part of the press from which, when wet, it can be easily detached—which operation, though, has to take place only now and then, when a thicker crust has formed. After the melted wax is poured on the press, the latter is closed with the left hand, as the weight of the upper plate itself produces the necessary pressure. Then the press is immersed in water for a moment, is opened on the table, and the foundation is loosened from it in a certain way by applying horizontally the blade of a knife. It is advisable that an assistant take hold of the foundation to cut off what may adhere on its outer rim. Before one proceeds to make another sheet of foundation,

the press is again immersed in water; then it is opened, and what drops of water may adhere are let run off; what water does not flow off, is almost momentarily taken up (swallowed) by the cement.

I also notice by the same paper that a Mr. A. Enge, of Klein-Helmsdorf, has invented a machine to uncap honey-combs with. The depth to which the uncapping is done can be regulated. It can be done down to the septum. The machine has been exhibited and worked at the above-mentioned exhibition at Leipzig, and has "created quite an astonishment," and was rewarded with a premium.

St. Petersburg, Fla., Sept. 16.

A LETTER FROM BELGIUM.

MORE ABOUT THAT CONVENTION WITH A MEMBERSHIP OF 2000 BEE-KEEPERS.

By Prof. J. Verlinden.

You have been sending me GLEANINGS regularly since 1892. It is certainly the apicultural journal which I read with the greatest pleasure. It is full of useful and interesting teachings; and the hours I have passed in translating it have been very agreeable. It is with impatience that I await its arrival at my

PROF. VERLINDEN.

table, and I then run over it eagerly. In order to know better your Belgian correspondent who will henceforth write more frequently, I send with my letter three photographs. One is a plain vignette of your humble servant. Another represents me giving a talk on the bee;

for, aside from my duties as teacher, the government has commissioned me to give a score of conferences in this province. I can thus qualify myself as professor of apiculture; and this second picture shows Prof. J. Verlinden giving a talk, and explaining the mysteries of the hive. The third picture represents my family—my wife and daughter, taken four and

south there is a woods. The honey flora is not rich, hence there are not many bee-keepers.

Born Nov. 4, 1860, I was appointed teacher in school No. 3, in January, 1882. So for thirteen years I have kept bees here. I have had 37 colonies; but to-day I have but 11. I shall increase the number during the summer.

My straw hives are placed in a house-apiary having a capacity for 12 hives. It faces the south. The frames in the movable-frame hives, Dadant-Blatt type, are $16\frac{1}{2} \times 10\frac{1}{2}$; the other frames are $11\frac{1}{8}$ square. The hives are placed along a hedge, sheltered from the prevailing southwest winds, and face the east. The plan of the apiary was adopted two years ago. In front of the house-apiary there is a small space reserved for the cultivation of certain plants whose value as honey-producers I desire to ascertain. For example, there is borage, of which I sowed a packet of seed this year. Every year I renew the plantation, and make record of the going and coming of the bees to these flowers. That constitutes my apicultural sport. Near the house you see the poultry.

... I have the black bee of this country; but in my apiary situated on the land of Mr. F. Rainbeau, at Grand Hornu, two miles from here, I keep pure Italians. Mr. R. is the Director of Mines at Grand Hornu and at Marles, France. He was Chief Equerry under Napoleon III., and he married the daughter of His Majesty's private secretary. He is very rich, and intimately related to the Rothschilds.

The flora being rich here, the honey-flow is of short duration. May and June are the two months when honey abounds. Extracting is done during the first half of July.

My heaviest yield (1888) was 70 lbs. per hive. The average is about 43 lbs. We get but little section honey, as it is but little used. Comb honey in frames is most used. Extracted honey is widely used.

After my honey is extracted I let it ripen in a large can, so that the watery parts may come to the top, and thus allow the denser part to

PROF. VERLINDEN INSTRUCTING HIS CLASS IN BEE KEEPING.

a half years ago. [The first two being the best I herewith reproduce them in half-tone.—ED.]

Wasmès (Vom) is a city of 14,000 inhabitants, in a mining district. It has two churches, six brassworks, one tannery, four coke-ovens, one cork-factory, one manufactory of chicory and coffee, one brewery, two distilleries, three schools for boys and three for girls. On the

settle. Then, in order to make it granulate sooner, and have the granulation fine and thin, I beat the honey by means of a churn.

The honey sells for from 28 to 58 cts. per kilogram, or 2½ lbs.

GLEANINGS for Jan. 15 makes two quotations from *Progres Apicole*. Thanks. In your Jan. 1st issue, you say that "the Hainaut Bee-keepers' Association numbers more than 2000 members." The province of Hainaut, the most populous in Belgium, has about a million of inhabitants. Two thousand bee-keepers form a part of the federation; but many are not now in full membership. These 2000 members are divided into 34 sections, each one of which is entitled to three meetings a year. These three meetings are paid for from the treasury of the association. Besides, the sections can pay for additional meetings. Fifteen persons are commissioned to go over the province to give instruction in apicultural matters. The following year we form apicultural schools, like those already existing in Germany and in the United States. Each meeting teaches part theory and part practice at the apiary of one of the members of the association. The professor performs the operations. There are no very extensive apiaries in Hainaut. The largest, to my knowledge, does not contain over 50 hives. One person, half a mile from here, makes a specialty of apiculture. He has 250 or 300 hives in 7 apiaries, all straw hives, one story. He buys much honey of strangers, which he manipulates before sending it to its destination. The greater part of the members average only four hives.

In a future letter I shall speak of the different kinds of hives, and of the flora of each country in particular. I read with much interest Mr. Norman's Chat on European Matters. I hope he will not forget the Apicultural Federation of Hainaut.

Wasmes, Belgium.

[We are glad to hear from our Belgian correspondent, and hope we may hear from him further.—Ed.]

THE DARK AS WELL AS BRIGHT SIDE OF APICULTURE.

WOULD BE A PAUPER IF HE DEPENDED ON
BEES OR BERRIES.

By L. A. Dosch.

I have kept bees on a small scale for over 15 years. Last year we got a little honey; colonies were strong, and in good condition. White clover was burned out last summer by the drouth, also this year. The bees succeeded in storing a good portion of the fruit-bloom, and made a splendid start; but the drouth set in as early as April and May. It was so dry in Southern Ohio our corn would not come up. We had to replant and replant again to make sure of getting a stand of corn. The Big Mi-

ami River, which flows in sight of my place is so low that children wade it anywhere. All small creeks are dried up all summer. Farmers' cattle look poor—nothing but the bare earth to be seen in the fields. Cows can scarcely be kept in bounds by fences. Bitter weeds are devoured greedily if any are in sight. Farmers have been hauling water from the river all summer to plant tobacco, our main crop.

In the Miami Valley my bees never swarmed last year nor this summer. Bee-keeping as a business is out of the question in Ohio. Let the truth be said. Yes, we have some pleasant recollections of some very wet seasons ten years or more ago—so wet we could scarcely run a binder at harvest, for fear of sinking it out of sight. I wish we had some of those wet days. We could stand two every week. The wells are all going dry. Everywhere you can see the well-diggers at work sinking deeper and deeper for water. Never, in the history of Miami Valley, was there such long-continued dry weather. Hay is \$28 a ton; but farmers have none for themselves. There was very little to make. We are not saying this to complain; but these conditions surround us. Strawberries were of short duration; then raspberries came next. They came and went, but we scarcely realized their presence as it was so short. You might tell some people there is money in bees; but not the average Southern Ohio farmer. We do not write these facts to scare any one out of the bee-business; but I have read your Reports Encouraging and Discouraging, and felt prompted to write this for your readers over this vast land who used to live in good old Ohio. There seems to be a disposition on the part of your management of GLEANINGS to rather suppress such reports as this, and always speak in rather glowing terms of what the bees are doing for you. Now, we do not tell the half of what our suffering farmers have endured for the last two years; neither do we exaggerate in the least. That honey crops have been a dismal failure for a number of years is a fact, and we should be obliged to go around with our pants all torn if we depended on the "blessed bees."

We hope you will insert this letter, and not suppress a line, or cut out a line here and there, as you frequently do, until you cut it down to suit your taste, in trade-journal style.

Miamisburg, O.

[Friend Dosch, I have not a particle of doubt as to the truth of all you say regarding the weather; but there is a strain of uncharitableness in certain parts of your letter that I do object to most seriously; and that is, that we publish only the bright side of apiculture. If you will look at our back volumes you will see that we have published the dark side as well as the bright; but you should remember that bee-keepers are very much more apt to give their successes than their failures. Your last insin-

uation, that we cut and trim certain articles so as to pervert the meaning of a writer, is entirely without foundation. Much irrelevant matter that is written is necessarily struck out, otherwise GLEANINGS would contain 320 pages instead of 32. I would by no means say that the drouth is sent to you as a punishment for raising that which produces so much human misery as we all well know tobacco does; but how you can ask God to send you rain *in order* to raise a curse for your neighbors is one of those problems that are said to be past solution. "If ye keep my commandments, then I will give you rain in due season, and the land shall yield her increase," is a promise that I believe still holds good.

My good friend D., our stenographer, W. P. Root, submitted the above to me in reply to your letter. He wrote it immediately after reading your criticisms, suggesting it simply as a basis for what I might wish to say; and so, with the best of feelings in the world, I wish to add a little. Would a journal be profitable to its readers that would publish mainly accounts of floods, drouths, cyclones, and things of that sort? Where a lesson is to be learned, of course we can afford to give full particulars. But in the above you really, perhaps without knowing it, find fault with the dispensations of the Almighty. A year ago, when I passed through the southern part of the State of Ohio, I was delighted with the fertile fields and prosperous farming that met my gaze on almost every hand. I wonder if some of our readers in your locality can not give us something more cheerful, even though you have experienced every thing you mention. While your letter was in my hand, our book-keeper called my attention to the following:

My bees are doing finely. Hives run as high as 12 lbs. per day. I have them in the midst of 200 acres of alfalfa. R. L. SNODGRASS.

Gordon, Kan., July 18.

And the above, as you will notice, comes from drouth-smitten Kansas—the State that has suffered so much that for years it was almost a proverb. I quite agree with what my friend W. P. says in regard to the tobacco business. If I were engaged in any such industry I certainly should not think of asking God to bless my daily tasks.—A. I. R.]

NEW MEXICO AS A BEE-COUNTRY.

SIX MONTHS' HONEY-FLOW; A FAILURE OF HONEY CROP UNKNOWN.

By T. S. McClure.

Not since the brief mention made by Mr. Root on the occasion of his visit here several years ago, has any thing appeared in GLEANINGS with regard to bee culture in this place; yet this quaint old town on the Rio Grande can give reports all along this line that can be equaled by those from very few localities.

Here, within a radius of five miles, are two thousand colonies of bees, nearly all pure Italians, in eight-frame Langstroth hives—a rather crowded range, some will think; but the average yield per colony is just as high as when there were only ten stands of bees in the valley. The honey season begins with the fruit-bloom, in April; very soon afterward the surrounding mesa, mile upon mile, seems fairly alive with the busiest of bees, gathering the

fragrant nectar from the far-famed mesquite. Early in June we should have on each hive a full super of the whitest and most delicious honey that can be produced in the world. After, perhaps, a slight check, comes the alfalfa harvest. This plant blooms four times during the year; but the nectar from the later crops comes mingled with that of many wild flo. The tornillo yields as good honey as the mesquite; but much of the product of the late bloom, which lasts until October frosts, is of poor quality, and of amber hue.

What do you think of a six-months' honey season? And the best feature of all is, that a failure of the honey crop has never been known, nor has any disease ever appeared among the bees.

The pioneer bee-keeper of the valley, Mr. S. W. Sherfey, says that, in his sixteen years'

THOSE PETS.

experience, one year only was unfavorable, and he then averaged over 50 pounds of comb honey to the hive. The veriest novice is dissatisfied unless he is able to produce 100 pounds of comb honey to the colony, besides quite a quantity of extracted.

Bees always winter well out of doors, eating comparatively little, and requiring no attention.

A PLEA FOR ADOBE DWELLINGS.

When Mr. Root visited our town he was enthusiastic over our orchards and meadows, but gave his readers a very bad impression of our mud-built houses. Pardon a brief digression, and allow me to put in a plea for our adobe dwellings. With walls often several feet thick, which can defy alike the most intense heat of summer or cold of winter, the adobe is the house for the climate. Frame and brick houses are common, but are very much in disfavor. The adobe admits of a finish as

fine as marble. The pleasant roomy frame house with its wide verandas, which Mr. Root visited, and described as being the only frame house that he saw, *was entirely an adobe building.*

The numerous readers of GLEANINGS would be more than pleased to welcome Mr. Root should he ever carry out his expressed intention of visiting our valley again, and for a longer time.

[Our friends sent along a couple of photos, one of which we have reproduced in half-tone. In answer to a letter asking for the circumstances connected with the swarm on the hat, McClure Bros. write:]

THAT SWARM ON THE HAT.

The picture of the bees on the hat was secured in the following way: A photographer happened to be taking some views of our apiary, when a swarm came out. The apiarist shook a few of the bees on his hat, and about half of the swarm settled there, and a view was taken. We have an apiary of about 300 hives. The present honey season has been more than usually good, and that is saying a good deal. We ship a carload soon. **McCLURE BROS.**

Las Cruces, N. M., Sept. 11.

QUEENS SLOW TO WORK IN AN ADDED STORY.

By Dr. C. C. Miller.

Some of my experiences as to queens working in more than one story seem rather contradictory. When I have tried to force them to work in a story added above or below, they have seemed very stubbornly against it. I formerly had an impression that a queen in full laying, if changed into a different story or apartment, would be obliged to lay at least for a short time, and that, rather than let the eggs go to waste, she would lay them in any kind of cells to which she had access, providing they were not too deep.

In some cases I raised the story containing the brood-nest, put the queen into an empty story below, and put an excluder between. I have no exact memoranda of results, but I think there was no case in which she continued laying right along, and I think there was always at least a day or two of sulking.

Last year I tried to get brood in some half-stories by adding them above or below with an excluder between. They contained both foundation and old comb. The result was much less satisfactory than any thing ever tried with stories of full depth. I hardly think the depth of the stories had any thing to do with it, but the season was poorer. Looking at my book, I find I put a half-story over No. 57, May 14, A. M. May 15, P. M., I found no eggs, but found some May 16, A. M. I think this was one of the most successful cases.

At the other extreme was the case of No. 76. May 17 I put the queen above. By some means it was left till June 14, just four weeks later, when I found no brood or eggs in the upper story. Neither was brood to be found, nor eggs, in the lower story. I then put the queen into the lower story, and thought all would be well. But eight days later I found no eggs, nor did I find any later; and July 2 I found the old queen on the ground in front of the hive, when I killed her and ended the colony. A case of stubbornness with a vengeance, wasn't it?

In the same line of witness is the fact that it is an exceedingly rare thing to find a queen laying in one of my supers, although there is nothing to hinder a queen any more than a worker from going up. In this case, however, it may be that conditions are not to her liking as to thickness of comb, and separators may have something to do with it.

QUEENS GO READILY FROM ONE STORY TO ANOTHER.

On the other hand, I have had many cases in which queens have gone of their own accord into an added story above or below; and I think in every such instance they have continued to go back and forth, keeping up the brood in both stories. Friend Hatch says his queens will go into a second story; but, once there, they never go down again. When I first read that, I wondered just a little whether there might not be some chance for mistake somewhere; but I have great confidence in the man. It is possible that his different experience comes from different conditions. I wish he would tell us what kind of top and bottom bars he has, and how much space between them.

In my case, the top-bars were $1 \times \frac{3}{8}$, and the bottom-bars $\frac{3}{8} \times \frac{1}{4}$, with a full inch between them. The space between was filled with comb, so that really it wasn't so very different from a single story with frames of double depth.

SHALL THE BROOD NEST BE ENLARGED HORIZONTALLY OR VERTICALLY?

The question as to whether a queen will go back and forth from one story to another becomes one of importance to those who think as many as ten frames or more are needed during part or the whole of the year. I confess that I am at present inclined to enter the camp of such believers. Having handled extensively both ten-frame and eight-frame hives, the compactness of the latter, together with ease and convenience of handling, is such that I am loath to go back to the ten-frame hive.

If as good results can be obtained, or even if nearly as good results can be obtained by using two stories a part or the whole of the year, avoiding thereby the lifting of the heavier hives, then I want to hold on to the eight-framers. This will hold especially true with such as now have eight-frame hives exclusively, for a change to a larger size would mean a

heavy expense; whereas the trial of two stories of a size already in use would cost comparatively nothing.

With my present light, if queens will be induced readily to occupy two stories, here's something like what seems desirable, only with two seasons of utter failure I know practically little more about it than I did two years ago: At the beginning of spring, give a story of combs below with some honey, so that there will be abundance of stores, and so that the queen can occupy as many frames as she likes of the sixteen. At the beginning of the honey-harvest, whether the whole sixteen frames shall be left, or whether the number be reduced to 12, 10, or to a single story, is a question on which I desire more light. In any case, at the close of the white-honey harvest two stories will be put or kept in use, remaining till perhaps October, when one story will be taken away till spring. If the hives were to remain on the summer stands there would be no need to take away one of the stories at any time of the year, unless thought advisable to do so during the harvest.

I am very much afraid, however, that, with such frames as I should like, and with the desirable absence of burr and brace combs, the queen would not readily go from one story to another. Possibly that might be remedied by some sort of ladder of comb from the first to the second story, so the queen could go from one to the other without setting her dainty feet down upon wood.

I shall read this article with much interest when I see it in print, but I shall skip all but the footnote. I shall also look with interest for the kindly criticisms of others, for I very well know that I'm talking on a subject about which I know very little, but desire light very much.

Marengo, Ill.

FEW UNFINISHED SECTIONS IN THE FALL.
HOW NOT TO HAVE THEM; BEES CLUSTER-
ING OUT; WHEN IT IS AND IS NOT A GOOD
SYMPTOM.

Question.—Nearly every fall I have half or more of my sections in the unfinished or uncapped state; and especially is this the case the present fall, when nearly two-thirds of them are unsalable on account of not being capped over. Will you please tell us in GLEANINGS how this may be obviated?

Answer.—How to manage our bees so as to secure the greatest yield of comb honey is a question of great importance to all those who are engaged in producing such honey for mar-

ket; hence we often have articles on this topic giving us instructions regarding it. But comb honey is of little value unless properly finished or capped over; so that the thing which our questioner puts before us of "how to manage our bees so as to have few uncapped sections in the fall" is a question of nearly as much importance to us as the one spoken of above, which has occupied the thoughts and writings of very many. For years I was troubled by having from one-fourth to one-half of the combs in the sections not fully sealed at the close of the honey-harvest, which were salable only at a reduced price, if at all; but of late I have but few of such, even in a poor season. After experimenting for a year or two regarding the matter, I became convinced that the cause of the trouble was in giving the bees too many sections; and especially conducive to this was the plan of tiering up sections late in the season. How often have I, years ago, spoiled a promise of an abundant yield of comb honey by tiering up four or five days before the honey-harvest closed! To tier up sections profitably requires considerable tact; and especially do we want a thorough knowledge of the honey resources of the field we occupy. I often think that there is too much injudicious talk in some of our papers in regard to not allowing the bees under any circumstances to cluster on the outside of the hive, the idea being generally conveyed that, when bees thus cluster out, they need more room. Now, it depends upon when this clustering-out occurs, whether more room is needed or not; and hence I say "injudicious talk." If the clustering-out occurs at the commencement, or in the height of the honey harvest, then more room should be given; while, if at the latter part of the harvest, or in a time of honey-dearth, no more room is needed; for more room at this time results in the one case in many unfinished sections, and in the other an absolute waste of time used in enlarging the hive. To illustrate: During some seasons we have but a few days of honey secretion, and that often after the flowers which produce the yield are rather past their prime. At such times we often do not have on the hive one-half of the capacity which we would use in a good season, and for this reason the bees begin to be crowded out. Hoping that the weather may be good during the rest of the time that the flowers are in bloom we give double the room to our colonies, only to have it turn bad weather again, thus giving us only partly filled sections in the fall; while, had we left them as they were, all would have been finished. Well do I remember one such season when, in time of basswood bloom, we had bad weather up to the middle of the bloom. At this time I had on each hive a surplus capacity of about twenty pounds, when all at once the yield of honey became abundant,

and the bees began to be crowded out. Hoping that the weather might be good for some time, I spread the sections on a few hives by placing some empty ones between those nearly full, giving at most only about 40 pounds capacity, while, when all is favorable, I use 60. The result was, that the bees immediately took possession of the empty sections, while the weather turned unfavorable again; and when the season was over I got no more than five to ten pounds of capped honey from these hives, while those not touched gave twenty pounds of nice capped honey. In this case the bad weather was the cause, for the spreading was not carried far enough to be unreasonable; but in former years I have been the cause of the trouble by spreading or tiering up but a few days before the honey-harvest closed.

Again, after the basswood bloom had fallen there came on a very hot spell when not a bit of honey was to be obtained; and the result was, that the fronts of the hives were black with bees. According to the advice above alluded to, I should have given more room; and if the bees then persisted in clustering out I should smoke each colony until they all went in and stayed there. Any one can see at a glance that this would be just a waste of time, as the bees were doing just as well for me by clustering on the outside of the hive as anywhere. But, to return:

My plan of operation to secure all capped sections at the close of the honey-harvest is as follows: When the bees show, by building bits of comb here and there about the hive, that they are securing honey from the fields, I put on sections to the amount of about 20 pounds, and leave them thus till the bees are well at work in them, when I add about 10 pounds more room by placing it at the sides of those first given them. When this room is full occupied, I give more room at the sides to about the same amount given before; and were I using the tiering-up plan, I should have my surplus-arrangements so arranged that, at this time, I could raise up about one-half of the sections already on, putting empty sections underneath them, instead of raising up the whole 30 pounds, thus giving them more room, a little at a time, as the bees have need. By the time the bees fully occupy the room last given at the sides, the first 20 pounds given them is ready to come off; and when this is taken off, the partly filled sections on either side are drawn together over the center of the brood-nest, and empty sections given at the sides again to the amount which I think they will need. Thus I keep taking off and putting on sections, taking the full ones from the middle, and putting the empty sections at the sides until the season begins to draw toward its close, when, as fast as full ones are taken from the center, the others are drawn up till

the space is contracted to the original 20-pound capacity, or even less if I think it necessary. In this way the bees are given all the space they really need, while the chance for many uncapped sections in the fall is quite small. By a little study the tiering-up plan can be made to conform to the above, and worked on the same principle. I think that any plan which requires the tiering-up of from 30 to 40 pounds capacity, or the spreading-out of the same number of pounds at one time, is faulty, and a wrong policy to adopt, while the giving of a medium amount of surplus room as needed seems to me to be a wise course to pursue.

HOW AND WHERE TO KEEP COMB AND EXTRACTED HONEY.

Ed. Gleanings:—Can you inform us, or some of your readers through the columns of GLEANINGS, the temperature that extracted honey can be raised to with safety so it will not regranulate again? also the proper temperature for keeping comb honey.

We notice that the sale and consumption of honey in comb is greatly reduced by honey being held in fluctuating and cold temperature; whereas, if kept in an even high temperature it would not chill nor granulate, and become premature old honey to all appearances.

We have spacious rooms that we use for cold storage of butter and eggs in the summer, and are now emptying them and contemplate heating those rooms to the proper temperature for comb honey. These rooms are so protected that they can hold any temperature, so they will not vary five degrees in six months.

We believe that will be a great benefit to the honey placed in our hands for sale, especially for such as comes to us before cold weather. We think one reason why honey sells best, and gives best satisfaction in the early part of the season, is because, in the later part of the season, it has been exposed to extreme changes in temperature, and it stiffens or granulates in the comb, and the consumer, buying such once, doesn't want it again. We do not know of a honey-dealer who keeps honey in a warm room, but generally in an open store, where the doors are not closed in many places in the coldest winter weather. We know of two hundred cases of honey that was carried over winter in that way, and is now unsalable except for bee-food. The holders say it came to them December last, and was granulated then, and would not sell. I should like to hear opinions on the practicability of furnishing an even high temperature for honey; and I think that, if

grocers and holders of honey come to realize that cold temperature injures honey, many of them will not keep their stock of honey in the coldest part of a store, and, in many cases, in their ice-boxes, under the false idea that honey must be kept cool.

H. R. WRIGHT.

Albany, N. Y., Sept. 21.

[Good extracted honey, if brought to a temperature of not over 180° Fahrenheit, bottled and sealed *while hot*, will usually, if kept in a uniformly warm temperature, keep liquid for a year or more. Indeed, we had some fine clover honey, treated in this way, keep liquid for two years. But there is a great difference in honey. Some will candy much quicker than others. The riper—that is, thicker—the honey is, the longer it will keep liquid.]

Cold atmosphere is quite favorable to candying of both extracted and comb.

The temperature of the storage-room should be about that of a living-room—70°. Higher would do no harm, but is inconvenient and expensive.

Cellars and cold rooms, especially when subject to freezing, are poor places for honey.

In melting candied extracted honey, the temperature should not go above 180°, otherwise the fine flavor will in a large measure be destroyed. The usual way is, to place the vessel of candied honey in another larger receptacle containing hot water.—Ed.]

THAT HIVE DISCUSSION — WHY IT SHOULD BE CONTINUED.

Last number of GLEANINGS is at hand, with intimation that the discussion concerning big and small hives ought to cease, because it is a matter of locality. I have also received a private letter from a prominent bee-keeper expressing the same opinion. Now, right here I want to enter the *very biggest* kind of a protest—that, precisely because it is a matter of locality, it ought be fully discussed. We ought to ascertain in what localities and for what kind of honey-flows large-sized brood-nests give the best results, and where and under what circumstances small brood-nests are best. Methods of managements are to be taken into consideration, as the management in any given case must vary with the kind of hive employed.

ADRIAN GETAZ.

Knoxville, Tenn., Sept. 20, 1895.

[As we have received a good many letters of similar import, and only one protest against the hive discussion, we will hold our columns open for a while longer. The question, I think, is indeed an important one, and personally I should be very sorry to have it stopped now—just on the eve of getting, as I think, a few more pointers and a better understanding of what *locality* has to do with it.—Ed.]

THAT HIVE DISCUSSION.

Keep up the discussion about the size of hives. I have tried from one up to twenty frames, and prefer ten to either more or less. I may tell you the reason why, later, if you care to know.

West Lodi, O., Sept. 5.

JAS. BOLIN.

[Yes, by all means let us know.—Ed.]

THAT NICE HONEY OF YORK'S; IS IT FROM THE ROSE OF SHARON?

In reading GLEANINGS for Aug. 15, page 637, I see that you have had a visit from Mr. York; and the description of his honey exactly answers mine; and as I had been trying my best to find out its source, I thought I would write you to say that the only possible source seemed to be the "rose of Sharon." My apiary (three hives) in our place is in a well-built-up town; but as the rose of Sharon is a pretty flower, nearly every yard has one or two trees of it.

If the tree named grows in near Chicago, Mr. York will undoubtedly find it the source of his honey. Perhaps I should mention that there are two kinds of the flower—the single and double; and while I could never find a single honey-bee on the single-flowered bushes, they fairly swarmed on the double, both red and white. The honey I have looks almost black in the comb; but when held up to the light it looks quite light.

Have taken 50 lbs. of comb honey from my hives this year, 2 colonies spring count, the most of it being this rose of Sharon, and the rest about 15 lbs., being basswood. Fall flowers are in full bloom, giving plenty for winter, and perhaps a little surplus.

E. LOIZEAUX.

Plainfield, N. J., Sept. 10.

[I don't know whether Mr. York has the rose of Sharon in the vicinity of his bees or not. The only way to prove whether the honeys are one and the same is to exchange samples.—Ed.]

SQUARE IRON TANKS OF LARGE CAPACITY FOR HONEY-STORAGE IN AUSTRALIA.

A few months ago I read some articles in GLEANINGS about the fitness or otherwise of galvanized-iron tanks for storing honey, such tanks being principally used in California by large honey-producers; but I haven't seen anybody recommending the tanks I use. The tanks I have for honey-storing are square iron tanks, made of stout iron plates, the seams closely riveted, very strong, and painted red outside. These tanks are used on board ships for holding water, and are also sent out to Australia filled with groceries, but principally with malt for the breweries. They hold 200 to 400 imperial gallons, equal to 3000 and 6000 pounds of honey.

I have at present eleven of those tanks in use—six of 6000 capacity, and five of 3000; three of them for over eight years in use, and they give every satisfaction. Some have had honey in them for 3 or 4 years. Before using I clean them well, and wax inside.

FL. PETERSEN.

Wattle Flat, N. S. W., Australia, July 25.

[If I understand you, these tanks are of plain iron—i. e., ungalvanized. Such tanks, especially if waxed inside, would no doubt give good service; but they would be rather expensive. Plain iron, if painted on the outside, would be just as good, and perhaps better, than the zinc-

coated metal. Honey, when in actual contact with iron, is an excellent rust preventive, and it is possible such tanks as you describe, and not coated with wax inside, would do very well.—ED.]

STAMPED NUMBER-TAGS FOR HIVES.

To those who want a hive-number, and are not afraid to pay for a good article, I will say any stamp-works can furnish you brass checks, $1\frac{1}{2}$ to 2 in. in diameter, $\frac{3}{8}$ thick, with number stamped on, and a hole to put a screw through. These will last 100 years, and then be good for 100 years more. Drive a brad in the front of the hive to hang them on. I use them. Cost is nominal. F. H. RICHARDSON.

LaCleda, Mo., Sept. 3.

W. J. C., Okla.—Bees will work on a ripe watermelon that has been broken. During a scarcity of honey they are quite apt to take any broken fruit while the juice is running. They would not gather enough in any case from a watermelon to do any perceptible harm to the winter stores.

H. M. S., O.—Years ago, as you may have noticed in the A B C book, we lost quite heavily, owing to the fact that the honey made from cider killed the bees during the winter. A safer way would be for you to extract all the cider honey, and feed sugar syrup. The cider mixture may be given them next spring, when it will do no harm.

J. B., Va.—If you have difficulty in finding your queens, use queen entrance-guards, illustrated and described on page 11 of our catalog. Attach one in front of the hive, and shake all the bees down at the entrance. As the bees pass in, watch for the queen. She will be barred out by the zinc, and can be easily caught. This plan is often used in finding black queens; and if you have defective eyesight it is one that you could probably use to good advantage.

W. W., S. C.—We usually advise bee-keepers to stay where they are. Bees do pretty well in almost any locality of the United States. California (at least the southern part of it) stands at the head; then comes Colorado, Arizona, Florida, New York, and Pennsylvania. But certain portions of the States named are barren of honey. If you have any particular locality in view you had better write to some person at the postoffice, and learn whether bees are kept; and, if so, whether they pay.

G. R., Ky.—It all depends upon the season of the year as to how soon the black bees will disappear after the introduction of an Italian

queen. Forty-five days might be long enough during the busy part of the summer; but I should expect to find a few back fellows in the hive all summer. If the queen be introduced in the fall, you will likely find black bees in the hive all through the following spring. As to how to Italianize, we would refer you to first column of page 32 of our catalog, third paragraph; or, better, the A B C of Bee Culture.

HANS MOURNS THE LOSS OF HIS BEES.

I haf much truble mit mine bees,
Dey haf dis vinter most all freeze;
Dey gets all ofer froze,
From der het down to der toes;
Und I say, "Hans,
You know yust how der muneey goes,
Ven you py some more bees."
Oh my! I veel so very sad;
Dis vinter use mine bees so bad.
I denk I take der rest
To pet mit me
Und cuver dem yup mit der close
To keeps dem from geding any more froze.
Mine vife Beky says she yust knows
Der bees no like to be shut up mit der close.
I denk, "Hans, you nose not
Vot you bees apout,
Or you deach does bees
Rite away to eat some krout,"
Den, oh my! you smell dot hunyes
Yust forty miles away.
I yust vait und see
Vat mine vife Beky haf to say.
Mine vife Beky say I make someding out.
Ve yust shweep dot room and clean it oud,
Und bring in does bees,
Und dot barrel of krout,
Und does bees makes honeys
All de vinter oud.
Dot vife Beky she bees so smart
I yust lofe her mit all mine hart.
Ven we bring does bees in,
Von dakes mine vife on der chin.
I say, "You look a liddle oud,"
Ven von sthicks her on der shnout.
She runs to dot barrel of krout—
Dot dakes der pain already oud;
I haf no dout does liddle bees
Yust would like some limberger cheese.
I see all does big bee mons
Gifes problems to make oud;
Und I yust gife dot problem
Apout der bees und krout.
Dey can yust tole me
If dot hunyes don't bee so very fine
I denk I ot to no dot,
Ven I eats him all der time.
I denk if does bee mons
Solf dot problem oud
Apout mine bees und krout,
Dey will hafe to sharpen der prain,
Und shweep the cobwebs oud;
But I bees so happy,
Und ven I dakes der hunyes oud
I can yust smell
It bees flavored up mit krout.
I feed mine bees limberger cheese und krout,
I denk I peets all der bee mons
Geding der hunyes oud.
Der bees none flafared so nice as mine,
I denk it bees so very fine.
Ah, Hans, old poy, you bees smart;
Of does bee mons you gets der sthart;
I yust lofes dot hunyes mit all my hart.
Vots der madder mit dot Rambler?
He says such funy dings,
He no likes the vimens—
Dey bees angles
Mit der liddle vings;
I denk if he bees a noin,
Der liddle wings dey bees a groin'.

HANS VONDERBLINKEN.

We are uniting, and shall begin to feed this week.

So many have asked to have the hive discussion continued, and as only one votes against it, we decide that it is the wish of our readers to compare notes along this line a little further.

THE usual article from Rambler, owing to a misconnection, will have to be omitted from this number. His "Echoes," however, is a good substitute. The series will be resumed in our next.

I HOPE that committee appointed by the last convention in Toronto, to formulate a plan or a basis of consolidation of the North American and the Bee-keepers' Union, will be ready to report soon. Let's see; this report was to be forthcoming within a month; and that time will be up now in a few days.

GLEANINGS from now on till Jan., 1897, to new subscribers, for the price of one subscription—\$1.00; or four-months' trial subscription for 25c. A large number of extra copies are printed for this number; and if you happen to be one of the new acquaintances, we hope such acquaintance may be continued.

THAT half the California honey is adulterated (see article by C. W. Dayton, in this issue), is a condition of affairs that I can not believe is true; and if not true, I'd like to see it disproven at once before it finds wings and flies like wild-fire all over the country. The bee-keeping interests have suffered already fearful damage by false reports. Now, ye Californians, let's have the truth; and if you can not give us facts, give us honest expressions.

A BEE-KEEPER so well and favorably known through the frame bearing his name, Julius Hoffman, of Canajoharie, N. Y., and whom I visited on my first bicycle-tour, has recently lost a little five-year-old girl, "the pet and sunshine of the home." The home seemed dreary and sad after this loss; but the cup of sorrow was not full yet; for, on the 2d of September, the eldest son was taken away. GLEANINGS extends its sympathies.

WE receive about this time of the year a good many specimens of honey-plants for identification. Some of them we can name, but many of them we can not, owing to the fact that the plants are dried and often badly mutilated. We formerly, at some expense, employed a botanist to name all such specimens, through these columns; but beyond the satis-

faction to the one furnishing the specimen in knowing the name, there was but little interest in it, and the Botanical Department was discontinued. If you forward specimens to your State Botanist at the capital, or wherever the agricultural college is, he will give you the name and other information regarding the plant, free of cost. If you have no such botanist, write to us and we will do the best we can; but be sure to send fresh specimens in as full bloom as possible, and see that they are properly packed so as not to receive damage in the mails.

NEW METHODS VS. OLD.

THE editor of the *Progressive Bee-keeper*, in commenting on the fact that we had gone back to the old-fashioned method of raising queens, has this to say:

I too find it more pleasant and profitable to rear queens (in fact, do a great many things) the way I first learned how. I never form nuclei until after the queen-cells have been built in full colonies, and I proceed as follows: I select strong colonies, and take the queen and all the brood from them. In place of these I give them a frame containing eggs from my breeding-queen, in which they will build queen-cells. When the cells are capped over, I transplant them to eight—all but the two outside frames—and leave all alone for a day or so, when the bees will have them all glued fast to the combs. Should there be more than eight cells, I destroy the poorest ones. Should there not be eight cells, I use them in the manner stated above as far as they will go. When all is ready I divide up this colony into as many nuclei as I have frames with cells attached, and add to each nucleus a frame of brood from some other part of the apiary. This method may not be scientific, and it may be a slow and expensive way to get queens; but I am sure I get good queens this way, and with me the above is the "good old way."

FEEDING SUGAR AND COLD WATER; IS PERCOLATION NECESSARY?

NEIGHBOR VERNON BURT fed his bees this year with sugar and cold water of equal proportions, without resorting to percolation. Of course, the sugar did not all dissolve before the first feed was taken; but more water was added at the next round, until it was all taken up. It is possible that this plan will answer very well providing the bees are fed early, or not later than October 15, for this locality.

MR. F. A. Salisbury, of Syracuse, N. Y., has for years fed his bees with a food prepared by mixing equal parts of sugar and water in an ordinary extractor, the reel of which is revolved until the sugar is incorporated into the water. We have tried this, but could not succeed in making a clear syrup—much of the sugar would still remain undissolved, and we accordingly used the percolator plan last fall. I am now beginning to feel, however, that a perfect union of the water and sugar, so that a clear limpid syrup is the result, may not be essential; that a mixture of sugar and water, even though

the former is not all dissolved when fed early enough for the bees to ripen it, may answer just as well. If this is true, it is not necessary to go to the expense and bother of using artificial heat and more or less elaborate melting-tanks.

Last year we proved, to my satisfaction at least, that syrup made by the percolating process was just as good as that made by the use of artificial heat, and far more convenient to make and feed.

As a caution, I want to say again that, for *late* feeding, or when the nights are cold enough to make the clusters contract up, it probably will not be safe to feed this half-and-half cold mixture; old-fashioned thick syrup—two-thirds sugar and one-third water, thoroughly mixed in a melting-tank over fire, should be given.

It occurs to me that, having mentioned the percolator feeders, I ought to describe briefly the one we used last fall, for the benefit of new subscribers. Into a one or two gallon crock put by measure an equal quantity of sugar and water; be sure the crock is level full. Over said crock lay three or four thicknesses of cheese-cloth, and on top of this a large dinner or pie plate. Invert the whole, set it in the upper story of a hive, and it is ready for business. Sapp-pails, without bails, and cleated boards in lieu of plates, may be used, and, on a smaller scale, a saucer and common tumbler.

Later.—Since writing the foregoing I have had a talk with our apiarist. He doesn't feel so hopeful that the mixing of sugar and cold water, without running it through a percolator, will do. At all events, the sugar-and-water mixture doesn't seem to be accepted very readily from the Miller feeder. The trouble is, the sugar settles to the bottom, and the thin watery portion rises to the top, where the bees are, and is so thin, indeed, that they do not take to it. In the case of the *crocks* and plate, above mentioned, the bees work at the *bottom* near the sugar, or where the syrup is the thickest.

OUR LATEST PERCOLATOR FEEDER.

We are now using, with great satisfaction, cleated boards with a three-inch auger-hole in the center, in place of the plates. The crocks are filled half and half, as previously explained; the flannel or cheese-cloth is then laid over, after which the cleated board with the orifice in the center. The whole is reversed, and the percolated syrup is taken by the bees at the opening in the center of the board now under the crock. We prefer this arrangement because the bees take the feed faster.

If you wish to know how to make a large percolator—one that will give you a half-barrel of syrup in a few hours—see GLEANINGS for October 15, last year, page 804. If you do not have the copy, we can send you one for 5 cents. Of course, these large percolators are used only

for making syrup indoors, the syrup being fed in the regular way in ordinary feeders.

DEATH OF DR. C. V. RILEY.

THAT distinguished scientist, Prof. C. V. Riley, who, till recently, held the position of United States Entomologist, which he resigned but a short time ago, died on the 14th of last month as the result of a fractured skull from a bicycle fall. In his special department of science (entomology) he seemed to be without a peer. In his official capacity he rendered important aid to the farmer, and especially to the fruit-grower, by discovering ways and means for the destruction of insect-pests. From the last *Scientific American* I take the following:

In the past few years, two of his studies have produced epoch-making results. One is his famous emulsion of kerosene oil, milk or soap solution being the emulsifying agent. Having found that this was an infallible insecticide, he had to devise means for applying it, and invented the "cyclone," "eddy chamber," or "Riley system" of nozzle for spraying it upon trees. Another of his achievements was the introduction of the Australian ladybird, *Vedalia Cardinalis*, into California, to destroy the white scale, which was then ruining the orange-groves. The result was simply magical. Since then the insect has been introduced elsewhere. It is interesting to note that other attempts of the same sort that have been made in California, against other insects, either against his advice or without his endorsement, have not had the same success. His discoveries in relation to the phylloxera alone were enough to give him international renown, and his recommendations have been followed by grape-growers in all parts of the world. He was a most voluminous writer; a bibliography of his writings, published by the Department of Agriculture, five years ago, showing over 15,000 titles.

Prof. Riley honored by his presence the North American convention which was held during the winter of 1892, '93, at Washington, D. C. At that time he read a paper which was listened to with marked attention and interest. In this he pointed out what the government had done and proposed to do for the bee-keeping interests of our country. Both he and Prof. Wiley, then Chief Chemist of the Department of Agriculture, created a pleasant and lasting impression on the bee-keepers who were fortunate enough to be in attendance upon that convention.

GOD'S LATEST GIFT TO A. I. ROOT AND WIFE.

On the anniversary of their 34th wedding-day, at half-past nine on Sunday evening, Sept. 29, 1895, was born to their eldest daughter, Mrs. Maude Root Calvert, a little girl, giving them a granddaughter in addition to the grandsons, Howard and Leland. May God give grace and wisdom to both parents and grandparents to bring up the precious charge in wisdom's ways!

ON THE WHEEL, AMONG THE POTATO-GROWERS.

September 14 I opened my eyes in a pleasant little room in the home of my cousin, D. E. Fenn, of Tallmadge, O. The first thing was to get my drink of hot water. Then my cousin and I took a seat in his easy buggy (for he is somewhat of an invalid too), and we rode around his potato-field. Perhaps the soil in the vicinity of Tallmadge, Summit Co., O., is the ideal potato ground—a loam partly of clay, with just enough sand and gravel to make it just right after it has been supplied with humus and the requisite fertility. The field in question was, in the spring, a heavy growth of clover; but, clover seed being scarce, the seed sown was from some distant point; and all at once cousin Fenn became aware that a weed he knew by reputation years ago, but had not seen for some time, was coming up thick all through his clover, and just getting ready to blossom. The only way to rid the farm of it entirely was to turn it all deep under ground—clover, weeds, and all. Even the clover was just coming into bloom. His sturdy German hired man did the job complete, plowing deep, and then working the ground up till it was fine and mellow. I think it was late in June when the potatoes were planted—Monroe Seedlings and four barrels of the new Craig Seedling, the latter furnished by your humble servant. The potatoes were well cared for, and they were a sight to behold, especially when contrasted with the field of a neighbor over the fence who “farmed it” in the good old-fashioned way. And, by the way, there would not have been any bugs of any account on that field of about 20 acres had not this same neighbor kept supplying a reinforcement from his own field. The hired man had picked them off on the side of the potato-patch as fast as they got over and through the fence. While cousin Fenn’s Craig Seedlings are making a good show, they do not compare with the two acres at the Home of the Honey-bees. We got back just in time for my beefsteak. You see, I manage to find it when mealtime comes around, no matter where I am.

After breakfast the wheel and I lighted out for cousin Wilbur’s, a son of D. E. Fenn. He was milking the cows, so I talked with the children till he had finished. By the way, before I reached the house I climbed over the fence so as to walk through—no. I did not *walk* through, because it would have been too much work; but I rode my wheel alongside of the handsomest-looking field of potatoes I think I ever saw in my life. Now, hold on a bit. There was not a longer and stronger growth than on my own Craig Seedlings at home—no, not as much; but the foliage was all young, thrifty, and of that light, tender, dazzling green that reminds one of springtime. You will remember I told you that, on the 4th of July, I saw a hundred bushels of Monroe Seedlings piled up in his cellar, almost as hard and firm as they were when dug. Well, on the 5th of July he planted several acres of these potatoes. They came right up; and, as if realizing that time was precious, they just put in their best ticks. The flea-beetles had gone, and there was not any neighbor near by who had potatoes the old-fashioned way, so there were not any Colorado bugs to bother them. Every leaf was clean and perfect—no perforations, no mutilation by insects of any sort. But the vines were knee-

high, and just about covered the ground; in fact, he had decided not to cultivate them any more, as the horses did so much damage tramping the vines.

“Cousin Wilbur, have you ever planted potatoes by the acre as late as this before?”

“Only once. Then I planted them the 6th of July instead of the 5th; and I got them into the cellar all right, without injury from frost, other than that the tops were killed before they had done growing; but the potatoes kept over winter all the better, and kept through until July again all the better.”

He did not plant all of that 100 bushels, for good eating potatoes were scarce and high during the fore part of July, and he sold them for table use rather than plant them. His Craigs were planted much earlier, because they need a long season in which to reach maturity. His acre of Craigs looked about like his father’s.

I told the friends I must hurry off, as I expected to visit Terry, then Chamberlain, then go to Cleveland, call on my doctor, and reach home before night. My good friends thought it seemed almost incredible that I, a sick man, should undertake so much in a single day.

Ten miles or more on the wheel, and I ran right down into the lot where Terry himself was digging his Freemans with the potato-digger. Three men were picking them up; and his son was kept rather busy looking after the empty boxes, loading up the filled ones, and keeping the whole work going on without any hitch. I remembered my experience, given in the A B C of Potato Culture, in bothering a man when he is running a potato-digger, and a gang of men who were getting them up and moving them into the cellar at the same time. Terry’s potatoes were ripe, and the vines dead. You see, he works with a comparatively early potato like the Freeman, New Queen, and others, that he may get in wheat, after the potatoes. There has been some complaint about the Freemans being small. They were not small on Terry’s ground, I can tell you, even though he has in his locality suffered from the drouth almost as badly as anybody. His potatoes were all of nice shape—clean and handsome. It was time for my hot water, and I begged to be allowed to go into the kitchen. A steaming tea-kettle stood right on the stove, and I was permitted to help myself. Friend Terry explained to his wife that I was on a hot-water “diet.”

“Why! But, Mr. Root, you don’t *live* on hot water and *nothing else*?”

“Oh, no! But I do live on hot water and beefsteak.”

“Well, we have plenty of hot water; but, dear me! where are we going to get beefsteak for your dinner, out here in the country?”

I laughingly explained to them my program for the day, and said that it was already time for me to be off. I rather expected that I should find them in the field, digging potatoes;

* After selling out all our potatoes I looked over our cellars and discovered a few odds and ends on the 12th day of July last. There was also about a peck of Craig Seedlings kept for possible tardy customers. A piece of ground where early peas had been taken off was selected, and potatoes planted on the 12th of July, and now the vines almost cover the ground. There certainly will be a tolerably fair crop. Years ago I used to try this late planting, and fail every time. I can not understand why Wilbur and I succeed just now unless it is because of the abundant fall rains and late warm weather we have been having for the last two or three years; or possibly we are learning how, and have got our ground in better shape for fall potatoes. But I tell you it is fun to see them growing, and making great tubers so rapidly during the cool pleasant days of the latter part of September.

and my half-hour's visit had abundantly satisfied me for making the trip. At just about my usual mealtime I stood before the landlord of the hotel at Hudson, O., and explained as follows:

"My good friend, I am under the doctor's care, and eat nothing but lean beefsteak. I am going to make you some trouble, but I am perfectly able and willing to pay you for it all. If you haven't it in the house, please get me from the meat-market a full pound of their best tenderloin steak. Have the butcher trim off every bit of fat, muscle, and bone, and pay him his price, then have it nicely broiled, not overdone, and call me to dinner. I shall probably be asleep on this lounge here in this sitting-room."

In less than an hour I was refreshed by sleep and an excellent meal of pure beef. When I went to pay my bill, the landlord said it was only 25 cts.

"Why, my good friend, 25 cts. won't pay for the meat I have eaten, let alone your time and bother."

"Well, our price is 25 cts. to everybody, and I don't see how we could charge you any more."

Now, friends, when you say the world is all bad, and when people make special strictures in regard to landlords and hotels, please remember there are exceptions. I had hard work to get this man to take more than the regular price, even after I had explained that I called for something outside of the regular line, and that I proposed in the commencement to pay extra for just what I wanted.

In a little time more the wheel landed me at the pretty home of W. I. Chamberlain, who carries on his farm as a sort of experiment station for the *Ohio Farmer*, of which he is one of the associate editors. He has about 36 acres in potatoes of different varieties. The field is so large I thought it quite convenient to take my wheel along while we made investigations. Besides he has a nice good wagon-road along by the side of it. We examined and tested more kinds than I can remember now. But the best of all, with his ground and his management, was the Sir William. It is a rather late potato, like the Craig and the Rural New-Yorker.

Perhaps I should mention that I found friend Chamberlain and his good wife at the dinner-table. As my time was so limited I was permitted to sit down to the table with them so we could talk meanwhile. They had the Sir Williams for dinner, and, of course, they were beauties. The way they cracked open and rolled out like popping corn, exhibiting their floury contents, was enough to make anybody's mouth water, let alone one who had not tasted a potato or any other vegetable for more than six weeks. Of course, the talk was about potatoes. In the midst of it, friend Chamberlain jumped up like a schoolboy and lugged in a basket containing some that were not used for the noonday meal. Something has given me a wonderful love for every thing in the line of potatoes during the past few weeks. Probably it is because I can not have any. But the doctor promises to reward me now before many weeks. Well, friend Chamberlain took along his spading-fork, and we dug into ever so many hills all over the field. The Sir William is certainly ahead of all others in yield. The potatoes were nearly all large—a large, long, white, handsome potato—almost no small ones at all. The Rural New-Yorker, that ran right along beside them, seems to come next to the Sir William.

Before I was half through, my watch reminded me that I should have to make time

and let the Rambler "ramble" indeed, or I could not reach my station, seven miles away, in time for the 2:10 train. The road was pretty fair; but as I neared Peninsula it was very much up hill and down. I imagined I could hear the whistle of the coming train; and we (the wheel and I) plunged down some fearful long steep hills in a way that reminded me of those of the Ozark Mountains a year ago. I reached the station, full of life and spirits, just a few minutes before the train. A brother-wheel-man came close on my heels.

I reached the doctor's office in Cleveland just before the closing-time Saturday night. Several patients were ahead; but after we had become acquainted a little in the waiting-room, those who could, kindly gave way for me.

"Doctor, I think it a little ridiculous to call a man sick who can eat a pound of beefsteak three times a day, and ride twenty or thirty miles over the hilliest roads in Northern Ohio. Hadn't you better turn me off and let me go?"

After making some examinations he replied:

"Well, you are doing tiptop. You need not have any more *ground* meat unless you choose; but it seems to me that lean meat, and nothing else—that is, if you will be guided by me—is what you need just a little while longer. Yes, you are getting thin in flesh, that is true; but that won't do you any harm. If you should come down to 100 pounds, instead of your present 115, it would not hurt you a bit. It is not the number of pounds that a man weighs that counts, so much as it is the stuff he is made of, what there is of it."

I was at home Saturday night just a little after sundown, and not tired out either, from my big day's work. In fact, I had been so full of enjoyment that I felt more like having another trip just like it than any thing else. But I slept a solid hour and a half as soon as I had finished my supper. Pure, wholesome food, regular hours, pure water to drink, rest whenever it seems to be needed—are they not the three great essentials to life, health, and happiness?

FLORIDA TRAVELS.

From Lake Helen, on my return trip I passed back again through New Smyrna, clear around to Palatka, making a brief call on our good friend Aug. Leyvraz, at Francis postoffice. In this locality there has been rather a setback of late years. Land right around the station at Francis depot was worth \$50 an acre ten years ago; but at the time of my visit the whole tract had been sold to a party at \$6.00 an acre, and the proprietor was busy clearing up the ground, and planting Niagara grapes. One peculiarity of the way they do things in Florida—yes, and California too—is to launch out in a new enterprise by planting acres and vines by the thousand. I could not learn that anybody had made a success of Niagara grapes right in that locality; but in some places in Florida the Niagara grapes had been sent into northern markets out of season, and had brought 30 or 40 cents a pound. I should start a *quarter* of an acre; and if that succeeded I would increase the acreage, and so on, feeling my way as I enlarged. It may be urged that life is too short for this slow process; but I think life is too short to take so many chances, and shipwreck a man even before he owns any thing, comparatively.

Toward sundown on the same day I was landed in the beautiful town of Ocala; and, in fact, it is one of the handsomest and most business-like places I found in Florida. Just as I stepped off the train, a neat-looking schoolboy about twelve years of age (he attracted my at-

tention because he was about the age and height of Huber) accosted me very respectfully:

"Mister, would you like a place to stay over night?"

"Why, my young friend, that is just what I should like. Are you a runner for some hotel?"

"No, I am not a runner, but I can furnish you a nice bed for 25 cents."

"Are you sure the bed will be clean, and that there will be plenty of windows so I can have lots of fresh air for the low sum of 25 cts.?"

"I think the bed and the room will be all right, because my mother takes care of it. And if you should want a good supper for 25 cents, my pa will furnish it to you right over there."

I got a good supper, and I talked with the "pa" and the boy. The railway dining-stand kept by said "pa" was close to the depot, on expensive ground; but the home-like sleeping-room was off a little way were property was less valuable. Now, while so many people are saying (and a great many say it in Florida) that there is no way to make a living, I would commend the example of this father, mother, and child. While the father looks after the dining-room, his boy meets passengers as they step off the train; and the mother in the home, a little way off, provides pleasant, wholesome sleeping-rooms for the great traveling public.

There is a railway from Ocala to the renowned Silver Spring; but it runs trains only one trip a day, and I could not wait, so I chose the more expensive way of going over in a carriage. Just now I feel incompetent to do Silver Spring justice. Here is a spring that pours forth a volume of water sufficient, in one spot, to float a steamer; in fact, it forms the Ocklawaha River. You can stand on the platform at the side of the spring, and look down into the immense crater nearly a hundred feet. The water seems to have something supernatural about it. There is a dazzling crystal transparency that enables you to see even small objects perhaps plainer than you would in the air. A colored man took me in a boat, and pushed out so quietly that there was scarcely a ripple on the glassy surface. He named the different springs as we passed over them, while in breathless wonder I leaned over the boat with my face close to the water. Pretty soon he announced "Ladies' Pahlah," meaning that the enchanting picture in the depths below was named the "Ladies' Parlor." In the first place, there was a sparkling sandy bottom. This sand, owing to the deposition of chemicals, I suppose, glittered with all the colors of the rainbow. Then there were sea-mosses, and vegetation after the manner of beautiful ferns. This vegetation was also decked with rainbow hues. Some of it was like flaxen hair floating in the many currents of rushing waters as they poured forth from the dark depths opening here and there. Beautiful fish slowly and gracefully moved here and there through the avenues and luxuriant vegetation of this enchanted garden. It seemed to me as though I could stay there for hours; but the guide could not spend very much time for 25 cents—at least he thought so. I finally gave him an additional quarter to push up a little way along that wonderful river, down where two steamers come every day.

The trip by steamer from Palatka to Silver Spring, if I remember correctly, is about \$10, or \$6.00 one way. My ticket was already purchased, however, by rail, at a very much lower price, and so I did not take the river trip. The latter also occupied a great deal more time. A lady who came down in the boat said there was not much opportunity for sleep, because the boats were almost every minute crashing

through the tropical foliage along the river-banks. Of course, they might trim it off; but vegetation grows so fast under the stimulus of the sulphurous spring water that it would probably be a task to keep the whole river trimmed up.

After my colored guide had taken me back I understood that he slipped out of showing me one of the most important springs, even though I had given him double pay. Let me remind the managers of these pleasure-resorts that this sort of lazy trickery advertises their places adversely, more than thousands of printed circulars could boom them. Niagara Falls people will please take notice. Dishonesty and cheat do not pay anywhere. It is just as true now as it ever was, that honesty is the best policy.

Silver Spring and the Ocklawaha River are indeed a most beautiful sight, and an electric railway should by all manner of means run to Ocala and back again. Pulling great lumbering stage-coaches through the deep sand on a hot dusty road is a shame and disgrace to the present age.

One more visit, and my invitations to beekeepers were all finished. Frederic Adams, Green Cove Springs, is a migratory—not beekeeper, but tinsmith. He gives us another illustration of what a man may do to support and bring up a family if he has the grit. He has a complete tinsmith's outfit loaded into a wagon, and he goes twice a week all through the town of Green Cove Springs, soliciting orders. He is prepared to do any thing from mending a five cent tin cup to putting a tin roof on a \$5000 hotel. When he gets a job of the latter kind, I presume he employs some help. I urged that he should have a shop in town. He has a running spring large enough to carry a water wheel and turning-lath. He goes out about his work at odd times, or a certain part of the week, then takes care of his grounds and home between times.

With the help of his son Frederic, and the assistance of the mayor, we finally alighted upon the father, with his wagon and tinner's tools. During my short stay we had a most agreeable visit, and drove up to the beautiful Magnolia Springs, where one of the great Florida hotels is located. Green Cove Springs is another of the beautiful springs in Florida. The water, however, is of a somewhat greenish tint. It is sulphur water, and too warm to be agreeable to most persons. But even after what I have said in regard to the enchanting beauty of these wonderful springs, scattered, it would seem, throughout almost all the United States by the hand of Providence, I want to say that Green Cove Spring in itself has a special claim above them all. It is right out in the open day—in a little park, as it were, in the midst of the town. The basin is perhaps 50 feet across. The depth may be 30 or 40 feet; and the whole bottom is literally paved with the whitest and most brilliant sand that Florida or any other clime ever produced. The water is of such sparkling clearness, and crystal brilliancy, that it brings forth an involuntary exclamation of delight from every visitor who first sets eyes upon it. I suppose my expressions were something like this:

"Dear me! is it really possible that this is a reality and not an enchantment? Did you ever! Did *anybody* ever see or dream of any thing so enchantingly fascinating? These waters must surely be as beautiful and refreshing and invigorating to the taste as they are to the eye."

Then I sprang for one of the bright new tin dippers. Others were drinking the water, and I supposed it must be good, the way they smack-

ed their lips. It is really too bad to find fault, after all I have said; but the water was too warm to be refreshing; in fact, it tasted like the time-honored dishwater; and then I had just recovered from a fit of sickness, possibly caused by drinking from sulphur springs, and I knew it would not answer at all. I am told, however, that, like other sulphur waters, when exposed to the air, and then cooled with ice, it is very palatable. I never thought, at the time, to try any of the Florida waters after boiling. As I write, however, I feel pretty sure I could drink them hot after a sufficient lapse of time after my regular meals.

Before I bade friend Adams good-bye I had quite a little confidential talk with him; and his closing remarks still come up in my memory together with the memory of that beautiful Green Cove Spring, only more refreshing. As nearly I can remember, he said something like this:

"Mr. Root, I especially wished to have you make me a visit. I am not much of a bee-keeper now. In fact, I do not take GLEANINGS because of what it has to say on bee culture. There is something else that interests me. For many long years I have been in the habit of reading my Bible more or less every day. For a good many years I did it from a sense of duty, and not because I was particularly interested in it. I want to tell you now, however, that, for several years back, the Bible has been growing more precious to me every day. Now it is a joy and pleasure to make it my daily reading. I love it because I believe it is God's message to his children, and I am trying to bring up my motherless boy and girl in the fear of the Lord."

As he gave my hand a parting pressure and wished me Godspeed, I recalled to mind that, during the afternoon, when we were hunting for the father, I had enjoyed having a very earnest talk with the younger Frederic; and he almost gave me his promise to commence then and there, from that day forward, to seek the kingdom of God, and his righteousness. May God's blessing, and may the Holy Spirit, finish the work that I in weakness had only just begun.

OUR HOMES.

And he shall turn the heart of the fathers to the children, and the heart of the children to their fathers.—MALACHI 4:6.

ALMOST A MAN.

A few days ago I was much moved by reading a little book by Dr. Mary Wood Allen, entitled, "Almost a Man." Its line of thought was a little different from the one I am going to talk about to-day; but still it set me to thinking of the boys around us and in our homes, who are *almost* men, and of the girls who are *almost* women. It set me to thinking that a good many times even their own fathers and mothers hardly realize that the children are children no longer, but almost men and women. It was only yesterday, in the busy part of the day, when letters were being passed about the office from one to the other, that the following touching appeal was all at once held before my face:

Dear Brother Root:—While I was at the State Fair my son, X. Y. Z., ran away in a most unfortunate manner. I send you the letter he left. As a truthful explanation of our relations, he never took any interest in our business; had learned to drink, use tobacco, and gamble, and I could not help keeping up a never-ceasing protest. He has many good qualities, and I can not abandon him.

I want him to return at once to his duty. Write to him, and help me save my darling son. A. B. C.

I read it over; and I hope that the dear friend whose name appears at the bottom will forgive me for deciding, before I had gone further, that he was at least *somewhat* to blame. Before discussing this further, however, let us consider the letter inclosed with the above:

Father:—I am about to do something that I dread the worst of any thing I ever attempted. I can not keep the tears back when I think of leaving the dear old home; but I am afraid we are so poorly calculated to live together, that it is not advisable for us to try it any further. I do not blame you altogether. I know I have often done wrong myself; and we both being wrong is what caused the trouble. I do not despise you now (as you may think); I wish you the greatest possible success, and hope you may get yourself into circumstances where you will be a great deal happier than you ever were with me.

I may have done wrong in taking as much with me as I did; but it seems to me as though I deserve some consideration, as I do not expect to get any thing after I leave this time. I fully appreciate what you say about the chance a person has who goes out in the world alone now, and I should think you would be willing for me to have something for a little start at least. I intend to go out to work, and save my money and hunt up a good location, and get into bees as soon as possible.

I do not like the *backward* way I have taken in getting away. It makes me sick when I think of it, and I am *very* sorry now I ever did it this way; but it is too late now. Somehow I thought it was the only way.

Father, I will tell you where the key to our trouble is. It is in the fact of my being of a *naturally unsocial nature*; but I don't think I am to blame for that. I think if I am out among people, and on my own resources, it will benefit me in that line. The reason I am not going to bid the folks good-by is because I know that, at the word, I should lose all control of myself. It is bad enough to leave the way I will, to think of leaving all the neighbors and friends. I have to grit my teeth and turn the subject from my mind. I do not expect to have half what I have been used to having here; but what I am after is more agreeable personal surroundings. I know that, under the circumstances, as we have been living I would ruin all chances for myself, and do no good for you or any one else, and at the same time spoil my health and whatever good nature I do have.

I do not want to drop you now altogether. I should like very much to hear from you often, for I know your intentions are the *very best*. When I get where I am going I will write to you the first thing. Repeating the wish that you may be happy and successful in all your undertakings,

I am your son,

X. Y. Z.

P. S.—I took just seven cases of honey.

Both of the above letters are exceedingly touching. Indeed, they will bring tears to many a parent's eyes, and perhaps also to the eyes of many a son or daughter. I do not know the boy's age; but whatever the age may be, I suppose he is at that critical period that I spoke of—almost a man.

When I was about 17 years old I was bashful and timid. I did not know how to act, and was afraid of society; but all at once there came a reaction. Something new seemed growing within me, and I, like friend X. Y. Z., felt as if it would do me good to get out into the world. While I still maintain that there is no friend to be found like the father and mother, I am at the same time forced to the conclusion that it oftentimes does a boy good—yes, and his father good too, but oftener the father than the mother—to let him go away from home awhile. My father and I were very much unlike—at least, when I was 17. In fact, our tastes ran in such different channels we were not very much "in touch." Mother, however, was a sort of bridge between us two. I longed for some expressions in regard to the mother in

both of the above letters. May be God has taken the mother away. If so, may the dear Savior come between that father and son, and cast out Satan, for it is all Satan's work, and both father and son are surely to be pitied.

Well, when I was 17 I had formed my project of going away from home. I was helping father one Saturday afternoon, drawing corn-fodder. Now, in those times I did not like corn-fodder, nor horses nor pigs nor cattle, nor muddy corn-fields. But I worked pretty well that day. With much fear and trembling I told my father what I wanted to do. Perhaps we had talked it over in a general way somewhat before. I told him my plans, and that I wanted a five-dollar bill to complete my outfit. I wanted it that very day. He was silent for quite a spell. Finally he stopped his work; his face softened into a smile, and he took out the old familiar leathern pocketbook. Oh how much good it did me to see that smile! I knew how scarce five-dollar bills were, and I knew how he needed them to prepare for winter, for my parents were comparatively poor in those days. He surprised me somewhat by handing me the money so readily, and made some pleasant remark to the effect that, if my plan ended in failure, I would learn something by experience any way. Yes, I did. I got out of money, and was sick at a hotel. But I was too proud to write home, so I worked and got some money, sent back to the hotel for my things, and six months afterward I came home on a visit. Oh what a delightful day that was! I was a little better dressed than when I went away; and, at least in my own estimation, I was ever so much more of a man. The six months away from home had been a grand school to me. I had learned something of the wickedness of the world; but the thought of the home, the mother, the father, and sisters, had held me pretty well from the evils I met. Did my father do a wise thing in helping me to go off when he needed me greatly at home? I think he did. Most of the time I was not far away from my older sisters. But I was loose and free, and had a tussle in making my way through the great selfish world, as some people call it.

I am afraid, dear friend A. B. C., that you have not taken just the best plan with your boy. Please do not feel hard if I suggest that you two have not been in touch as you might have been. I know it is pretty hard to hold a parent responsible for the sudden turns that a boy in his teens may take; but above all things I think a father should be careful to see that there is harmony between him and his boy. Never mind the honey he took. Do not question whether he had fairly earned it or not. Tell him it is all right, and do anything or sacrifice almost any thing to still preserve friendly relations. A man should never quarrel with his wife. He should not talk about her to the neighbors. He should be ashamed to mention her faults to any living being. Now, I think it should be pretty much the same with his boy. If your boy is bad, do not tell it to *anybody*, unless it is to go to the great God above and tell him your troubles as you pray for your boy. Has not the boy got it pretty nearly right when he says you two are poorly calculated to live together—that is, such *has* been the case? Now forgive me, dear friend, for saying that such need be the case no longer. There is a way by which we may be changed over, and become different. "Ye must be born again," so the Savior said. The love of Jesus Christ can so baptize us over anew that we shall be no longer the same we were before. I wish I could feel, dear father,

that you were praying for that boy, and that that boy could be moved to remember you in his prayers, for I believe that even a boy prays sometimes, for even a boy at times has thoughts and feelings that God accepts as a prayer. When you two are praying for each other, how quick will the new relations come!—the harmony, the peace, the loving confidence, that should always exist between father and son!

Now, dear readers, please do not imagine that I am such a model father as I am holding up to you. My conscience accuses me while I write. But, may God be praised, I can, right in my own home, find an illustration of what I am trying to teach.

These September days have been very warm—yes, and the nights have been warm too. Mrs. Root has much trouble in sleeping during sultry nights. With the opening of school and the approach of house-cleaning time, and other things I need not mention, many cares have come upon her. She has been greatly wearied of late. When I rush over from business for my ground meat or hot water, I find her flying about from one thing to another with a speed and untiring zeal that is often a rebuke to me. She is toiling for those she loves. You suggest hired help. There is work to be done in a household that nobody can be hired to do. It was at the close of one of the hottest days. I knew that she was tired out, and that she had slept but very little the night before. Her duties were almost ended; but a restless youth, "almost a man," burst in with his boyish enthusiasm, and wanted something of mamma. I was going to utter a protest; but they got off together in another room. I peeped in to remonstrate against it; but they seemed so busy, and in such perfect harmony in their plans and work, that I forebore scolding until I could look on a little. I had once or twice been inquisitive in regard to this new hobby of that "young Root"; but neither mamma nor Huber seemed inclined to enlighten me. I had faith in them both, however, to trust them and not insist. Now, what do you think they were up to? Why, mamma, tired out as she was, was fashioning some sort of great thick mitten, padded on the palm, so the wearer could catch a base-ball, no matter how hard or how swift it was thrown, and not hurt his hand. It had to be just exactly so to please the boy, and nobody but mother could do it. It was pretty late bedtime when the thing was finished. Why should I mention this trifling circumstance—something so natural and so common in almost every household? Because, dear parents and dear children, it illustrates the point I am trying to make. That boy and that mother have always been a *unit*. She has stood by him from his boyhood up; and I verily that, boy as he is, he would stand by his mother through *fire* and *flood*. Yes, I think the bond is so perfect that all the arts of the evil one—that all the machinery of vice and dissipation could never entice away that boy—at least, while his mother is living to hold up a warning hand. That same boy loves his father, and his father loves him; but the bond of sympathy is not like that between the boy and the mother. I fear the father has never yet reached the point where he would make the sacrifice that the mother does, that he might be in touch with the child. Had he come to me when I was tired out and unfolded to me his plans for something about base-ball, I fear I should have said that base-ball does not amount to very much any way, and that it was time for us all to go to bed. I fear I should not have been willing to get down on the floor by that boy's side, and

win a place in his heart that would hold stronger than massive cables or iron chains—a bond of sympathy that would hold him secure when Satan commences, as he will a little later, just as that boy begins to feel the throbbings of manhood and ambition through his boyish frame. May the dear Savior bless these words and make them plain to the fathers and mothers and the children. Excuse me for just one more illustration in this very line.

There is also in our household, thank God, one who is "almost a woman." Her studies were interrupted a year or two ago in consequence of overtaxing her eyes. She must drop her education for the time being, or somebody must be eyes for her. Different members of the family took their turn; her relatives lent a strong helping hand; but sooner or later success or failure depended on the *mother's* assistance. The mother did not, in her girlhood, have the advantages that most of us do now; but through long years, oftentimes as I close my eyes in sleep at night, I have listened to the reading and the recitations from the school-books; and history, physiology, and even Latin have been gone over; and the mother has surprised me again and again by giving me facts gleaned from schoolbooks, that I knew nothing about. We thought it a pretty hard dispensation of Providence when physicians declared our daughter must not use her eyes to read; but the mother's life has been refreshed and broadened by her school studies, even after she was fifty years of age. I mention this for the encouragement of other mothers. A man, or woman either, can commence and successfully master every branch of study taught in our common schools, *after they are fifty years old*, if they only have the will to do it.

I have been told the English people are clanish—that they hang together; that the different members of the family will stand up for each other. From my experience with one daughter of "Merrie England" I half believe this to be true. May God grant that it is true; and may England's sons and daughters both teach us Yankees wholesome lessons to the extent of being clanish enough to make the family circle hold together.

Now a word to this boy. Dear young friend, let me whisper to you to bear with your father, if need be. Do not have trouble with him if it be a possible thing. Write kind and friendly letters to him often. Make him a visit now and then, no matter what it costs you. Keep up and preserve friendly relations. Read that grand old story about the prodigal son; read it again and again. And, oh if I could only hope, dear boy, that my poor efforts during this pleasant afternoon could have the effect of calling your attention toward that precious book, the word of God, how happy I should be! Very likely I shall meet your father before many years. Perhaps I may see you too. Would it be hoping for too much to believe that I might some day hear you tell me you have given up tobacco, strong drink, and games of chance for ever? May be your father is a little mistaken about these things. Won't you set to work to convince him he is wrong? You speak about being naturally unsociable. Why, my dear friend, that is one of my failings, if I don't guard against it and look out for the tempter. Won't you write briefly and tell me that I am at least pretty nearly right about it?

HOWARD H. RUSSELL'S TEMPERANCE WORK IN OHIO.

Some years ago our pastor, in his opening prayer one Sunday morning, took occasion to

thank the Lord for our enemies, for they tell us of our faults. Well, now, it seems the enemies of temperance are doing a still greater service in the State of Ohio. They are advertising the Anti-saloon League. At a meeting of the Ohio State Liquor League, recently held in Springfield, O., the president, in his address, made the following speech, which we copy from the *Cleveland Plain Dealer*:

"Few of you are fully aware of the powerful organization that has been effected throughout the State by Rev. Howard Russell, devoted entirely to this view of your business. He was our most bitter enemy in the Ohio legislature two years ago. He, with his aids, came near pushing legislation through the House of Representatives that would have meant death to the liquor-traffic. Since then he has tripled the strength of the Anti-saloon League.

"We are in a position to wipe the liquor-traffic entirely out this winter," are Russell's own words. Rev. Mr. Russell says the time for organization is not when the legislature is in session, but when it is not in session, and be in position to make a powerful front when it does convene. These are my sentiments exactly; and the Ohio State Liquor League has used every effort to do likewise; but, gentlemen, we have abundance of room for improvement, which I am afraid you will learn before this time next year.

"I have been through the mill, and will predict that, unless the liquor-men, who have millions of dollars invested, come closer together, become more thoroughly organized, discard all petty jealousies, and work as a unit, there will be legislation railroaded through the coming legislature that will wipe 75 per cent of the liquor-dealers entirely out of the business."

WHITTAKER OR MULTIPLIER ONIONS, FOR FALL PLANTING.

I have had 25 years' experience in planting these same onions *in the fall*. No, it is not too late. I always tell my audience, when talking on "revised edition" gardening, to plant a bed of Whittaker onions the time that farmers are sowing the first wheat; but I planted earlier this year than ever (Sept. 13), for the reason that it is so exceedingly dry here; and when it comes wet we may be detained. If your ground is not very mellow, incorporate wood ashes; for the greatest trouble you will likely have will be that your ground will get *hard* by spring. Guard this point. I have quit mulching in winter, but it is advantageous; but don't mulch heavy. A little corn-fodder is good; but old tomato-vines are best—they don't fit down to the surface so close, and the onions grow up among the vines. Brush are good if they are just the kind—any thing to prevent the ground from freezing and thawing, for it has a tendency to raise the big bulbs out of the ground. Plant a little deep, and hoe the crop as soon as they start to grow. I have had them start very little in the fall, and still make an excellent crop. I have, when times were better, planted a good large onion, such as I will send you, and in the spring I pulled 18 onions from the one, and sold them at 10 cts.; but now times demand a nickel bunch, and we put in a dozen for a nickel. They are the best-selling vegetable I ever grew. In the spring we get southern onions here, three in a bunch, for a nickel; but a week or two later, when we begin with our nice fresh onions, the southern onion stops quick.

What may be called a "trick of the trade" is

to plant some smaller onions (same variety), only about the size of a guinea egg. These make three or four new onions only, but of course they are larger; but these are nice too; or, as the Irishman says, to "imbellish" the bunch. I will put in a few of the medium-sized ones, so you can try which you like best; but the medium take up room too fast, and don't turn out fast enough. I find nothing pays me better in gardening than to plant onions in the fall, and have them in market in April.

They are valuable, because, if onions are plentiful (*large* ones in particular), and dull sale, or if they start to grow, as onions sometimes do in warm winters, all you have to do is to plant them, no matter if they have grown 4 or 5 inches. The result of your planting will be a lot of small onions that are often valuable; if not valuable, plant again and get large ones. I do this; and unless I can get 10 cts. per quart I plant; and 10 cts. per quart means about 20 cts., because they are larger than sets usually are, and fill up twice as fast.

But this variety is valuable for another reason: They, as a rule, do not sprout nearly as readily as other onions, and are wonderfully dormant until in the *late* spring. Just last spring, onion-sets were 5 cts. per quart here; and, owing to their keeping quality, I was able to sell mine at 10 cts. Now, the large ones appear to sprout much more readily than the small ones. They should also be called *early*, because they come in a shorter time than other varieties of onions do if planted in spring.

Last spring I bought a bushel of these onions brought to one of the groceries by a Mrs. Taylor. They were not large, either. I planted them in very rich ground alone, to test the result of the investment. Before pulling-time I noticed from 5 to 7 onions or a bunch like the one I sent you by mail, apparently lying loose on the bunch of larger ones, the large ones yet green, and the small bunch ripe and ready to pick up, as they were loose, and lay unattached. I took over a bushel of small ones, worth three to four dollars; and when the rest were ready to harvest I had over four bushels of larger ones than I planted.

DR. F. M. MARTIN.

Mercersburg, Pa., Sept. 17.

□ The onions sent by friend Martin are remarkably solid and handsome. They look almost like the White Multiplier, but are of a bluish color. And, by the way, what is the real difference between Potato onions and White Multiplier onions, except that the Multiplier is white, and the Potato onions are straw color, or sometimes like what friend Martin calls the Whittaker onion? At \$2.50 per barrel, the price we paid him for these, we think there should be a large trade in them, if they are good keepers; and the larger ones are nice enough for anybody. His remarks in regard to the right kind of mulch agree with my experience exactly. Onions won't stand any thing that settles down flat and close, like stable manure, or even rotted straw. Old tomato-vines, and I should think bean-vines, where the beans have been thrashed out: evergreen boughs, or any thing that will stand up loose, letting in plenty of air, and yet proving a partial shade, is just about what we want for onions and a good many other plants that are almost winter-proof.

GAULT RASPBERRIES AND CRAIG SEEDLING POTATOES

The Gault raspberry-plant you sent me was planted on the 30th of April. By the 1st of Aug. it had put out 20 canes, measuring in all 54

feet. Two other canes now have bloom and berries on.

The Craig seedling potatoes you sent me arrived at the postoffice on the coldest Sunday of last winter, and were not taken out until Monday. They were frozen, all but six ounces. I now have 16 hills of the plants, and 60 side-shoot hills.

Garden City, Mo., Aug. 6.

G. J. YODER.

HUMBUGS AND SWINDLES.

ELECTROPOISE.

The latest circular sent out by the Electropoise people has on the outside of it, in large plain type, so as to attract attention, "Ministers of the Gospel." On looking closer you will see it reads "what ministers of the gospel say about it." Turning over the leaf we read the following:

The Electropoise is able to cure all diseases, no matter how various in character, because all diseases can be traced to one and the same source—weakness.

Now, these people have a good many times declared very positively that they never claimed it would cure *every* thing. How does the above sound? After my remarks on page 536 I sent for the instrument that was used at the time of the patient's death. It is one of the latest make, and I suppose it includes all the recent improvements (?). I used it faithfully according to directions, off and on, for more than two weeks, without being able to perceive any effect whatever. Mrs. Root has always been troubled for lack of sleep during hot weather. She also used the instrument according to directions; but instead of inducing sleep it kept her awake. She said the very idea of having something hitched to her ankle, and connected to a block of ice, was enough to keep a nervous person awake. Accompanying each instrument is a very pretty little book—leather-bound, gilt-edge, labeled on the outside, "Plain Directions for using the Electropoise." On page 8 we read:

□ Research and experiment through many years have shown that hydrogen and other electrically positive gases contained in the atmosphere, by their absorption, and passage through the skin and underlying tissues, in undue proportion, become the foundation of all the physical disturbances we call disease.

Now, will these ministers of the gospel, who are assisting to push Electropoise, please calmly consider the above statement? In the first place, hydrogen is not a component part of the atmosphere at all. It is found in water, but never in air. The expression, "electrically positive gases," does not mean any thing at all. There is no sense to it whatever; the same with the talk about "absorption," and "passage through the skin," etc. It is just jargon, humbug, and nonsense; and so on with the whole contents of the little book of 284 pages. It is really appalling to think any man of sense and judgment, or one who has any education at all, could be induced to fill a whole book with silly nonsense and unmeaning terms. Let me quote once more, from page 12:

It generates no current which is discoverable to the sensation of the patient.

□ The proprietors of the concern actually come out and declare that it produces no sensation perceptible to the patient at all. Therefore this thing without *sense, science, or sensation*, is what they are selling for \$25.00, and ministers of the gospel are helping on the work. Publishers of religious papers keep inserting

their advertisements, and unblushingly declare they are going to keep on doing so, with the above facts staring them in the face. I paid our friends who were swindled, \$5.00 for their \$25.00 instrument. If anybody else wants it for \$2.50 (is not this quite a jump, from \$25.00 down to \$2.50?) I shall be glad to sell out, book of instructions and all. If nobody can be found who has faith enough in it to give \$2.50 for a \$25.00 machine, then we will come down on the price still more. I tried to get some of the younger Roots to give it a test; but they simply laughed at their worthy parents for the pains they had taken to be sure there was no mistake about the thing.

Science Siftings, London, has taken up the matter of exposing Electropoise, for it seems they are already trying to push it across the water. They justly term it the "quack toy." We make one brief extract:

The Electropoise is an impudent and cruel fraud; and its very active proprietors are unblushing knaves who have conceived the notion of flooding our newspapers with fraudulent advertisements and raiding the attenuated pockets of our afflicted poor.

Special Notices.

We have a number of mismated Italian queens at 35 cents.

SEED POTATOES FOR FALL SHIPMENT.

Since prices given in our last issue, page 689, there has been some decline in the market. For instance, Beauty of Hebron will be as given in our last—peck, 15 cts.; bushel 40 cts.; two-bushel bag, 75 cts.; barrel of 11 pecks, \$1.25.

Monroe Seedling, Early Ohio, Early Puritan, Lee's Favorite, and Rural New Yorker, will be as follows: One peck, 20 cts.; bushel, 60 cts.; two-bushel bag, \$1.00; barrel (11 pecks), \$1.50. New Queen, Freeman, Burpee's Extra Early, 1 lb. by mail, postpaid, 15 cts.; 5 lbs., 35 cts.; peck, by freight or express, 35 cts.; bushel, \$1.00; 2 bushels, \$1.75; barrel of 11 pecks, \$2.50. Craig Seedling at prices given in our last issue, page 689. The Craigs are still growing as if their lives depended on it, no frost having interrupted them up to this date, September 30.

SIR WILLIAM POTATOES.

On page 689 of our last issue, a lower quotation on Sir William potatoes was made than the market price will warrant. It was a misunderstanding on my part—or, perhaps, a blunder of mine. Accordingly, that quotation on the Sir William is withdrawn. The following is, for the present, to be the price, and no orders accepted for less than a barrel:

Barrel, \$3.50; 5 barrels, \$16.25; 10 barrels, \$30.00. All will be shipped in October and November, in new full-sized apple-barrels, free on board cars at Hudson.

The potatoes will be of the crop grown by Mr. Chamberlain himself, the same as I described in our present issue, and are guaranteed to be true to name, pure from mixture, and averaging large size, with none below good planting size. They will be packed and shipped by Mr. Chamberlain.

JUTE SACKS FOR HANDLING AND SHIPPING POTATOES.

Of course, the potato-boxes are, all things considered, about the neatest and handiest thing ever gotten up, for handling or storing potatoes; but with the immense crop and low prices of this present season it is very often desirable to use sacks; and we have had potatoes shipped in sacks that came to us in very good order. The expense of transporting sacks is, of course, very much less than with boxes. After some investigation we have succeeded in finding a very strong, substantial jute bag, holding two bushels each, suitable for potatoes, grain, or almost any purpose that bags are ever used for, which we can supply at the following low prices: 10 cts. each; 90 cts. for 10; \$8.00 per 100; \$75.00 per 1000. A bag of the same material, holding only one bushel, 5c each; 45c for 10; \$4.25 per 100. If you would

like to see such a bag before purchasing, we can mail you a sample of either, at a cost for postage of 7 and 16c respectively.

GARDENING FOR OCTOBER.

Most of the gardening done now will be to save the crops from frost, and to make the most of every thing. Do not be discouraged, even if prices are low; but get every thing out of the way of freezing. Gather the beans as soon as dry enough; and if a frost threatens, do not wait for them to get dry, but get them into an open shed; spread them out where they will not heat, and many of them will ripen up nice. Fruit and even forest trees may be planted in the fall; and, when properly done, I believe there is an advantage in it. Look out for stuff, however, that is liable to be thrown out by the frost. If you have had experience, and know how to do it, you can succeed; but if you are new at the business, go slow until you learn the trade. Do not forget to hoe and cultivate cabbage and cauliflower that are not yet headed up. Now is the time to raise the finest cauliflower of the season; also look after the spinach and potato onions, and others that are to be wintered outdoors. You can keep strawberries growing right along until Christmas, if the ground does not freeze.

DRUMMOND'S ADDRESSES, ETC.

Most people have read or heard more or less of Henry Drummond's stirring, and, we might say, startling, exhortations to righteousness and right-doing. In fact, his one address, "The Greatest Thing in the World," had such a run that it was sold by newsboys on the cars, even though the price was kept up for a time to 25 and even 50 cts. a copy. When I first read it I made some mention of it in our Home Papers. But I protested at the outset against charging such a price for a pamphlet of 30 or 40 pages. We have succeeded, however, by purchasing 500 copies outright, in getting them so we can send them by mail for only 10 cts. each. Now, if you have never read "The Greatest Thing in the World" you certainly want this little pamphlet. It is handsomely gotten up, in paper covers, and contains 52 pages, and will probably be read by almost any one who picks it up and commences to read it, even if it is a sort of sermon; and it will bear reading again and again. I am so anxious to see it find a place on the reading-table of every home that I would almost send it free of charge if that were the right and proper thing to do; and we will, anyhow, do this: Every subscriber who sends us \$1.00 for GLEANINGS for one year, and in the same letter says he would like "The Greatest Thing in the World" as a premium for subscribing early, can have it free of charge.

Now, some of you may prefer to pay a little more, and have a neatly bound book—one that would be handsome enough to place on your center-table. Such a book is published, neatly bound in cloth, at the price of 75 cts. It contains not only the address, "The Greatest Thing in the World," but a brief sketch of Prof. Henry Drummond, and five other addresses, with an engraving of the author. It is a book of 127 pages, and the price, as I have told you, is 75 cts. by mail; but by buying a large number of copies we are enabled to furnish it for only 25 cents, if ordered with other goods, or 30 cents by mail. If you want something for a Christmas present, I do not know of a book in the world that will answer any better. Prof. Drummond is clear up to the front in all modern science and theology; and all mankind, no matter what their belief, seem to be united in acknowledging that he has done a great work in making the religion of Christ Jesus plain, sensible, and practicable. You need not be afraid of dry theology. Every page of his writings is alive, and up to the present time and present wants and needs. Perhaps you had better get the little ten-cent book first, and see if you do not agree with me, and want the larger one. We will send the larger book to any person, a subscriber, who keeps up his own subscription, and sends us one new name along with his subscription.

TO close out before uniting nuclei I will mail 1 untested queen for 50c. Order at once. Plenty nice queens on hand.

W. H. LAWS, Lavaca, Ark.

Daughters of Imported Italian Queen.

One for 50c; 3 for \$1.25; 6 for \$2.25; 12 for \$4.00. Safe arrival and satisfaction guaranteed. References: E. A. Sheldon, L. C. Tift, Independence, Ia.

CHAS. BIERY, Novi, Mich.

62 Colonies of Pure Italian Bees for sale cheap. In 8-frame Langstroth hives. Must be sold on account of removal.

F. J. GUNZEL, Claytonville, Ill.

Advantages of Bee-Escapes.

No sweat steals down the heated cheeks and aching back of the bee-keeper as the result of standing in the hot sun puffing, blowing, smoking, and brushing bees; no time is wasted in these disagreeable operations; and no stings received in resentment of such treatment; the honey is secured free from black or even the taint of smoke; the cappings are not injured by the gnawings of bees; and robbers stand no show whatever. If there are any broken burr-combs they are cleaned up by the bees inside the hive, before the honey is removed. **Leading Bee-keepers use the Porter Escape**, and say that without a trial it is impossible to realize the amount of vexatious, annoying, disagreeable work that it saves. The cost is only 20 cts. each, or \$2.25 per doz. As in the past, this escape is manufactured by the Porters, but The A. I. Root Co. has secured control of the sale for this country. Order of your dealer or of

THE A. I. ROOT CO., Medina, Ohio.

"The Southland Queen."

Send \$1.00 for the Southland Queen. Edited by the Atchley family. Plain, practical, and all fresh bee matter. Jennie Atchley is now conducting a bee-keeping school, that began in the June number. You can get back numbers.

A steam bee-hive factory; Root's goods; Dadant's foundation.

We have a fine lot of tested and untested queens for fall trade: Tested, \$1.50 each; untested, 75 cts. each, \$4.25 for six, or \$8.00 per dozen. Send for free catalog that tells all about queen-rearing, and sample journal.

W. O. Victor, of Wharton, Tex., took

45,000 Lbs. of Honey in 1894.

He offers Italian Queens—good, old-style honey-queens—untested, first order, to any address, at 50c each. Also bees in any quantity; 450 colonies to draw from. **Root's goods constantly in stock.** Prices to suit the times. Buy near home, and save freight.

HONEY COLUMN.

CITY MARKETS.

CHICAGO.—*Honey.*—We quote fancy white 1-lb. comb honey, retail, 15; wholesale, 14; second grade, 13; amber, 11@12. With colder weather and fruits out of the market, we look for a good demand for honey, as maple sugar and maple syrup are very high and scarce. Extracted, 5½@6½, depending on quality and package. Beeswax, 30.

S. T. FISH & CO.,

Oct. 8. 189 South Water St., Chicago, Ill.

ALBANY.—*Honey.*—We have a firm market, and stock moving off briskly. White clover seems to have been a short crop, and but little on our market. Buckwheat, however, is plentiful, and quality good. We quote white clover, 13@15; buckwheat and mixed, 10@11. Extracted, light, 6½; dark, 5½@6.

CHAS. McCULLOCH & CO.,

Oct. 8. Albany, N. Y.

BOSTON.—*Honey.*—We are pleased to note a little better demand for honey; but the California comb is keeping down the price of the Vermont. We quote Vermont comb at 15@16; New York, 14@15; California, 13, for No. 1 stock. California extracted, 5@6, according to quality.

E. E. BLAKE & CO.,

Oct. 10. Boston, Mass.

BUFFALO.—*Honey.*—We quote fancy honey, 15@16, with the receipts light; choice, 13@14; buckwheat moving slowly at 9@12. Beeswax wanted at 28 to 30. Extracted, slow sale in our market. Liberal shipments of choice could be placed here to very good advantage.

BATTERSON & CO.,

Oct. 9. Buffalo, N. Y.

KANSAS CITY.—*Honey.*—The demand and supply fair for comb honey. Demand for extracted light. We quote No. 1 white, 1-lb. comb, 13@14; No. 2, 12@13; No. 1 amber, 11@12; No. 2, 8@10; extracted, white, 6@6½; amber, 5@5½; dark, 4½. Beeswax, 20@25.

C. C. CLEMONS & CO.,

Oct. 4. Kansas City, Mo.

MILWAUKEE.—*Honey.*—This market is in good condition for shipments of honey. The supply on hand is not large, and the receipts only fair, while the demand is improving. The fruit season is nearly over, and the consumption of honey will increase from this time forward. We quote 1-lb. white, choice, 16@17; good, 15@16; fair, 14@15; dark, 8@10. Extracted white, in barrels, or kegs, 7½@8½; dark or amber, 5@6. Beeswax, 27.

A. V. BISHOP & CO.,

Oct. 5. Milwaukee, Wis.

CHICAGO.—*Honey.*—Honey is not selling fast, and market is nominal. We quote best or fancy, 15; but good No. 1 stock sells at 12@14; dark, 8@10; yellow grades, 9@10. Extracted very dull at 4½@7. The amber or dark grades are in large supply. Beeswax, 28@30.

R. A. BURNETT & CO.,

Oct. 8. 163 So. Water St., Chicago, Ill.

CLEVELAND.—*Honey.*—Our market is doing better on honey, and present receipts are picked up as fast as received. Fancy white comb in 1-lb. sections is selling at 17@18; No. 1 white, 15@16; choice, 14; buckwheat, 12@13. Strained honey, white, 7@8. Beeswax, 26@28.

WILLIAMS BROS.,

Oct. 8. 80 & 82 Broadway, Cleveland, O.

PHILADELPHIA.—*Honey.*—The honey market is very active, and choice comb honey sells quick on arrival; but low prices seem to prevail. Beeswax is moving slowly, not much demand, but is firm at present prices. We quote buckwheat, comb, 10; choice white, 12; fancy, 14. Extracted, 4@6. Beeswax, 26.

WM. A. SELSER,

Oct. 9. No. 10 Vine St., Philadelphia, Pa.

CINCINNATI.—*Honey.*—There is good demand for choice white comb honey at 14@16; dark grades found a ready sale of late at 12@14 in the jobbing way. Demand is good for extracted honey at 4@7. Supply of all kinds is insufficient. Demand is good for beeswax at 20@25 for good to choice yellow.

CHAS. F. MUTH & SON,

Oct. 9. Cincinnati, O.

KANSAS CITY.—*Honey.*—Stock of comb and extracted honey light. Demand good for comb. We quote No. 1 white, 15; amber, 13; dark, 10@11. Extracted, 4½@7. Beeswax, 22.

HAMBLIN & BEARSS,

Kansas City, Mo.

Oct. 9.

NEW YORK.—*Honey.*—There is good demand for comb honey, and choice stock is moving off freely. While the supply of fancy white glassed, and in paper boxes, is limited (owing to the short crop in New York State), California sends enough (unglassed) to make up the deficiency. We quote fancy white, 15; fair white, 12@13; buckwheat, 9@10. Extracted is in fairly good demand, with a large supply. We quote California, 5½@6; white clover and basswood, 6@6½; Southern, 45@55 per gallon. Beeswax dull at 27@28.

HILDRETH BROS. & SEGELKEN,

Oct. 10. 28 & 30 West Broadway, New York.

SPRINGFIELD.—*Honey.*—We quote white-clover honey, 16@18; buckwheat, 12. Would like to buy several tons of fancy white-clover honey, in 1-lb. packages.

PERKINS & HATCH,

Oct. 9. Springfield, Mass.

ST. LOUIS.—*Honey.*—Market very quiet. Comb, 10@12. Extracted, in cans, 5½@6; in barrels, 4½@5. Prime yellow beeswax, 25½.

D. G. TUTT GROCERY CO.,

Oct. 11. St. Louis, Mo.

DENVER.—*Honey.*—Since our last report there has been much change in our honey market. The shipments we have received run below those of previous years in quality. We quote No. 1 comb in 1-lb. sections, suitable for our cartons, 10@11. Extracted, No. 1 white, in 60-lb. cans, two in a case, 5@6. Beeswax, 20@25.

R. K. & J. C. FRISBEE,

Oct. 10. Denver, Col.

FOR SALE.—Choice extracted honey.

ELIAS FOX, Hillsboro, Wis.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from clover (tinted), 6c. Samples, 8c.

OLIVER FOSTER, Las Animas, Col.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty.

J. P. IVY,

Secretary Bee-keepers' Association, Phoenix, Maricopa Co., Arizona.

WANTED.—To buy quantity lots of fancy comb honey. Also to sell water-white extracted honey in 60-lb. cans.

B. WALKER, Evart, Mich.

FOR SALE.—Buckwheat and amber extracted honey in half-barrels, about 150 lbs. each; well ripened. Prices on application.

J. I. PARENT,

Elft Birchtown, Saratoga Co., N. Y.

FOR SALE.—1200 lbs. of honey, in 60-lb. square cans, 6½ cts. per lb., f.o.b. cars here. Sample by mail.

R. H. BAILEY,

195t Ausable Forks, Essex Co., N. Y.

FOR SALE.—We have 14,000 lbs. of choice white extracted honey, in barrels of about 400 lbs., at 6 cts. per lb., f.o.b. cars at apiary. Sample mailed for 8 cts. in stamps.

THE CROSBY CO.,

San Mateo, Fla.

Extracted honey in barrels at 6½ cts., or in 60-lb. pails at 7c.

CHAS. DADANT & SON,
Hamilton, Hancock Co., Ill.

Special Notices.

HONEY MARKET.

There is a brisk demand in the Cleveland market for choice white comb honey, and the supply so far is very limited. Honey is selling by commission men at 15 to 16c for choice white; and in large lots to jobbers, who buy outright, it brings about 14c. We could place a good deal more than we have been able to secure so far. We should like to hear from those who have some choice lots to market. There is not so much demand for extracted honey as for comb. Perhaps if we offered it put up in small attractive packages we should have a better sale for it. We offer choice white-sage honey or white Michigan honey, in 60-lb. cans, 2 in a case, at 8c; lots of 2 cases or over, 7½c.

ROOT'S SUPERIOR EXTRA-POLISHED SECTIONS.

We have just got into operation the past week a new and quite elaborate and expensive machine for the manufacture of section boxes, which not only secures more accurate and better work, but enables one man and boy to do the work which before required four or five to do. The sections we are now turning out are superb in every way. We can hardly see how it is possible to surpass them, and we question whether their equal is made. Having a very large stock of choice white basswood we are better prepared than ever before to supply beekeepers and dealers with a superior article, and we shall be pleased to hear from dealers before they make their contracts for next season's supply. Samples mailed free to those interested.

TRY US. We sell your Poultry, Veals, Fruits and all produce at highest prices. DAILY RETURNS. For stencils, prices and references, write F. I. SAGE & SONS, 183 Reade St., N. Y.

Peach Trees. All the best varieties, 10 by mail, 60c; by express or freight, 4c each.

WANTED.—To exchange safety bicycles, Barnes No. 4½ lathe for metal work, Odell type-writer, for honey, beeswax, or gasoline or kerosene engine.
J. A. GREEN, Ottawa, Ill.

Winter Losses

etc., etc. Successful wintering comes from a proper combination of different conditions. For clear, concise, comprehensive conclusions upon these all-important points, consult "**Advanced Bee Culture**." Five of its thirty-two chapters treat as many different phases of the wintering problem. Price of the book, 50 cts. The **Review** one year and the book for \$1.25. New subscribers get balance of this year free. I can still furnish queens by return mail at \$1.00 each, or \$5.00 for six. One queen and the **Review** for \$1.50. Queen and book, \$1.25. Queen, **Review**, and book, \$2.00.

W. Z. HUTCHINSON, Flint, Michigan.

THE TORONTO CONVENTION REPORT FREE!

A **Full Report** of the Proceedings of the North American convention held at Toronto, Canada, will appear in the *weekly American Bee Journal* immediately after the meeting, Sept. 4, 5, and 6. The first installment will be in the number for Sept. 19. If not now a subscriber, you can have that Report free by sending \$1.00 now for the *American Bee Journal* for 1896, as we will "throw in" the balance of the year 1895, beginning with Sept. 19, to new subscribers. Think of it! over 15 months (or nearly 70 numbers) of the old *American Bee Journal* for only \$1.00! Sample copy of *Bee Journal* free.

And, besides all that, each new subscriber will receive a free copy of the 160 page book, "Bees and Honey." Better send on your dollar at once, and join the procession. Mention this paper, please.

GEO. W. YORK & CO., 56 Fifth Avenue, Chicago, Ill.

Proof Beyond Doubt.

A customer, looking over my 400 hives in home apiary, said, "Where are your bees? Mine were flying all around thick this morning." I said, "Just stop; look down at any hive." He was amazed. They were just pouring in thick with their heavy loads. This proves two things—they can't be excelled as workers, and quiet.

I opened several hives. He had no veil; was in the apiary $\frac{1}{2}$ of an hour; was not bothered once. Try them. Untested guaranteed queens, 75c. Send for wholesale price list.

Vol. XXIII.

OCT. 15, 1895.

No. 20.

STRAY STRAWS

FROM DR. C. C. MILLER.

ABOUT THIS TIME we begin to whistle up our courage by telling how bright the prospect is for next year.

THE HUNGARIAN government in ten years has appropriated nearly \$40,000 for the advancement of bee culture. In seven years the products have doubled.

THE FIRST FROST here came Sept. 28—a hard freeze. Oct. 3 the bees are at work on sweet clover and on the few blossoms yet to be found on spring-sown crimson clover.

THE *Bienen-Vater* contains an account of bees carrying in the resinous little leaves from the buds of poplars and horse-chestnuts, carrying them with their jaws, evidently to be used as propolis.

A DRONE, we have always been taught, takes 24 days to develop from the egg; but H. W. Brice says, in *British Bee Journal*, that, after much and careful observation, he is sure it requires 25 days.

DECIDEDLY, I don't believe in many and long essays at conventions; but if every one was as meaty and discussion-provoking as that of B. Taylor at Toronto I don't know but I might change my views.

THE FOUL-BROOD bacillus, under favorable circumstances, increases by division about once every half hour, so that in 10 hours a single bacillus increases to a million! If you doubt that, figure it up for yourself.

GRAVENHORST has been wrestling with the conundrum, "Why do bees sometimes get nothing from clover when in full-bloom?" and got the worst of it. A young fellow like him had better fool with something easier.

IF BEESWAX from foul-broody colonies is used for making foundation before it is carefully cleansed, the spores remain in the wax, and no one then denies that foul brood may be conveyed thereby.—*Neuman, in Centralblatt.*

So far as my own observation is concerned, I agree with him that queens will pass readily from one story to another, the trouble I reported about getting a queen to lay in a second chamber being when she was confined there against her will.

THE STANDARD FRAME of Germany is about a sixth smaller than the Langstroth. Lehzen, editor of the excellent *Centralblatt*, thinks there should be two standards—the larger for regions with spring and summer flow, and the smaller for regions with fall flow.

THE ROSE OF SHARON, by which I suppose is meant the althea, on p. 742, is not the thing that gave the vanilla flavor to that honey York raised. The tree or bush is too tender to live here. Sometimes I've had a little suspicion the flavor came from sweet clover; but then, again, I don't know.

THE BEE-LOUSE, Dr. Balint says, is not a parasite, as heretofore supposed, but a commensal or table companion, merely sharing with the bee the food taken by the latter.—*Bienenpflege*. [I believe this is right. I never have seen a case, and I've seen a good many, where the queen or bee showed evidence of harm from the so-called louse.—ED.]

CHILLED BEES, stranded away from the cluster in the hive, are nothing very unusual; but I think I never saw such a thing outside the hive till this fall. Sept. 22 we had a 90° temperature, and at night it dropped 40 or 50°. Next morning I found a few bees chilled on the front of the hive where a cluster had been hanging out the evening before.

MY SYMPATHY is with the man who complains of alteration of articles in *GLEANINGS*. There's that article of mine on page 739; the very best part of it is suppressed—the editorial footnote. [Yes, that was an oversight—that is, the last paragraph of yours. I have been trying to figure out whether it was a joke on me or you. As to the footnote in question, see editorial.—ED.]

J. I. EARL, p. 731, takes a wrong meaning from that Straw on p. 583. I meant it was of more consequence to have a big harvest than to have

any particular hive, not exactly that "it wouldn't make any difference what kind of a hive." But will he please tell us *why* he thinks the bees are piling in the honey in the small hives and doing little in the large ones? And if the hives are changed, will the bees change their department?

LET UP A LITTLE, friend Root, on the Electropoise people, and go for the religious papers that advertise it just because they make money by it. ["Let up!"—My, oh my! You are using slang. But he is "going for" the religious papers. Notwithstanding that he has written letter after letter to those same publications, some of them still persist in putting the ad. in. Is it the almighty dollar that is at the bottom of it? God forbid.—Ed.]

IN CENTRALBLATT is given the following plan, discovered by Prof. Landolt, to detect paraffine in beeswax. Into a porcelain dish pour over a small piece of the mass sulphuric acid, and heat it, whereby the wax becomes blackened, and swells up through the gas generated. When the generation of gas ceases—which is stronger, the less paraffine is present—heat the mass again a few minutes and let it cool. If paraffine is present it will be found as a transparent stratum, easily separated from the surface of the black liquid.

SWEET CLOVER. So much testimony has come in to show that sweet clover is a good honey-plant that more is hardly needed unless to show that it yields enough to occupy the ground for honey alone. The testimony now needed is, to show that it is a good forage-plant. Let that once be established, and we may see it come in to general cultivation. [Both facts are, I think, well established; but the trouble is, the world does not know it. If the writers on bees for the agricultural press would take pains to emphasize them it would help the world to know it.—Ed.]

So, MR. ERNEST, in estimating the average yield you don't count failures. (See p. 691.) If a colony yields 25 pounds every alternate year, and the other years has to be fed 25 pounds to make it pull through, would you say the average yield was 25 pounds? Now will you "yield"? [No, I just won't. Your locality seems to be blessed (?) with a series of off years. In most localities, and especially with the small beekeepers, the seasons when the bees yielded absolutely no honey and have to be fed 25 lbs. are rare. Your supposed case is a rather extreme one.—Ed.]

SAY, ERNEST, in speaking of the crock feeder on page 745, why do you say, "Be sure the crock is level full"? Doesn't it work all right if only half full? [Unless the crock is clear brim full of sugar and water when it is inverted with the plate, a lot of the liquid will escape, owing to the air in the space not filled.

The sweetened water will bubble out and run down over the combs and bees, until atmospheric pressure on the outside equals the downward pressure of the sugar and water in the crock. When it is full the leakage does not take place.—Ed.]

THAT HEADLINE on p. 732, "Bees Necessary for Strawberry-fruited; indisputable proof," looks as though the matter were fully settled. But what's to be done with the hundreds of acres producing good crops of berries, and hardly ever a bee to be seen? Doesn't that headline need a little tinkering? [Perhaps so. But we have mountains of proof that the bees work on the blossoms. If we reason by analogy, that is, consider the value of bees on other fruit-blossoms, we must admit a good deal. The heading in question had reference particularly to the article under it.—Ed.]

GENERAL CORRESPONDENCE

WM. G. MALIN.

SKETCH PREPARED BY HIS BROTHER-IN-LAW,
THE REV. L. L. LANGSTROTH.

My acquaintance with the late W. G. Malin began more than sixty years ago. It was formed under very painful circumstances; and his consideration and kindness quickly won my heart. From that time till his death, in 1887, I knew him well. In June, 1855, he married my sister, Anna Louise Langstroth, second daughter of the late John G. Langstroth. She died Nov. 5, 1855. I am now in my 85th year, and I can truly say I never knew a better man. The extracts from the history of the Pennsylvania Hospital render any further testimony to his worth quite unnecessary.

WM. G. MALIN.

For nearly sixty consecutive years in the employment of the same institution as clerk, librarian, and steward! What volumes of eulogy does such a career speak, both for Mr. Malin and the managers of that institution! Where can a parallel be found?

The son of a small farmer, with very few educational advantages in his early life, how truly remarkable was his career as a self-made man! I need but refer to

the hospital-records, below. No words of mine could add force to them.

Shortly after the introduction of the English sparrow into this country. Mr. Malin expressed to me his indignation of what seemed to him such folly, in language somewhat as follows: "Brother Lorenzo, if the men who imported this pestiferous bird knew as much about it as I do, some would think hanging was almost too good for them! My father was a small farmer; and I can well remember that, just as soon as the wheat had reached a growth that tempted these marauders, we boys were sent into the harvest-fields before daybreak with a lunch to frighten away the sparrows, as soon as they made their appearance; and there we stayed until it was almost too dark for us to see our hands before us."

And then, growing more indignant at the bad work that had been so ignorantly undertaken, he went on: "Why, brother, in many parts of Europe a premium is paid for the heads of sparrows; and in some municipalities a certain portion of the taxes *must* be paid in the heads of this pest."

What immense injuries have followed similar carelessness in the introduction of the English rabbit into Australia, the Scotch thistle into Canada, and the gipsy-moth into Massachusetts! I remember well the attempt of the Commissioner of Agriculture, under President Lincoln, to introduce the Mexican honey-hornet into this country—an insect whose saw-like mandibles are so admirably fitted for piercing the skins of all kinds of fruits. Fortunately the colony of these insects, which was established in one of the public parks of Washington, perished after the first hard frost. The late Samuel Wagner, editor of the *American Bee Journal*, pointed them out to me before they died.

Dayton, O., Aug. 13. L. L. LANGSTROTH.

WILLIAM GUNN MALIN, A FAITHFUL STEWARD.

Mr. Malin entered the institution as Clerk, March 29, 1824, and remained in its service for nearly sixty years. At the expiration of this time, on account of his advanced age, he was relieved from duty by the Board, which, in consideration of his faithful, devoted, and long service, pensioned him, and offered him a home in the hospital during the remainder of his life. He died of pneumonia, in his apartments at the Hospital, August 2, 1887. When he first came to this country as an immigrant from England, in 1823, he was obliged to work as driver of a brewer's wagon; and out of his savings he returned, before the end of a year, to his parents, his passage-money to America. He was fortunate in finding more congenial occupation in the Hospital. He numbered the books in the library, and made a catalogue, which he presented to the Board, January 26, 1829, and it was ordered published. In September of the same year it was issued, together with an introductory sketch, also prepared by him, of the history of the Medical Library. Two years later, by direction of the Managers, Mr. Malin compiled a small work entitled, "Some Account of the

Pennsylvania Hospital; its Origin, Objects, and Present State," which was also published by the Board. In 1840, when the Department for the Insane was opened in West Philadelphia, he was appointed Steward, and assisted in organizing the new administration. Nine years later he was made Steward, and practically Superintendent, of the Department for the Sick and Injured, which position he filled until 1883, when he was retired from active duty. About this time he was complimented by having a dinner given in his honor by the Association of Ex-Resident Physicians, many of whom had been associated with him during his long service in the institution. The library was used in which to hold the banquet; there were flowers and speeches, and the faithful Steward occupied the seat of honor. On this occasion a life-sized portrait of Mr. Malin, in oil, was unveiled and formally presented to the Hospital by the Association of Ex-Resident Physicians.

William Malin, the grandfather of Mr. Malin, was a resident of Preston Capes, Northamptonshire, England, where his son, John Malin, was born, who removed to Woodford Halse, and married Mary, the daughter of John Gunn, of Banbury; of this union William G. Malin sprang, a scion of good English stock. His parents were religious, and of Moravian connection. The grandfather on the mother's side was a descendant of Olaf Rolfson, a noted Viking and Vice-Jarl under the Earl of Orkney and Caithness; the youngest son of the adventurous Norseman was named Cunni, and hence the surname Gunn arose in the family that claimed through its founder relationship to the "Lords of the Isles" and "Kings of Man," famous in story and song.

William Gunn Malin was born in Woodford, near Byfield, Northamptonshire, England, November 7, 1801; he had scant schooling at Eydon, as his father intended to equip him for no higher station than that of market-carrier to Banbury and Deventry. Being impressed with the idea that he was destined for better things, he took passage in a sailing-ship, the "Massasoit," for Baltimore; but a storm drove the vessel into the port of Boston, by which means he providentially escaped the danger of yellow fever which was then epidemic in his original place of destination. He made his way to Germantown, now a part of the city of Philadelphia, and found occupation temporarily. A year later he considered himself most fortunate in receiving the appointment as Clerk, and subsequently was appointed Librarian.

His handwriting was very legible, and so regular that it was almost like engraving. Mr. Malin was largely self-educated, and was a modest and diligent student. He loved books, especially old black-letter English volumes, preferably Bibles and works relating to the history of the Moravian Church, of which he was a life-long consistent member. Much of his leisure time was occupied in poring over his choice possessions, which included works in Latin, Danish, Dutch, French, German, Italian, with which he made so much progress as to be able to translate the portions in which he took the most interest. At his death he bequeathed his library in trust for the Moravian Church, at Bethlehem, Pennsylvania; and it was regarded as a particularly valuable collection, since it possessed unique copies and rare works on the early history of the Church, the fruit of many years' patient studying of catalogues and

correspondence with dealers in all parts of the world, and the expenditure of money which cost much self-denial to save. As a result of his wide reading, Mr. Malin was a well-informed man; and, although he did not seek conversation, being rather reserved in his manner, yet he showed by his remarks that he had good judgment, and possessed a mind conversant with a multitude of subjects in art, literature, and popular sciences.

In his intercourse with Managers and Physicians he was always most courteous, cheerful, and cordial in his manner. His long association with the physicians of the institution was unmarred by any unpleasantness; in fact, in consequence of his uniform amiability of demeanor many of the residents and members of the medical staff became his life-long, cherished friends. Mr. Malin, soon after his transfer (in 1819) to the Pine Street Hospital, married Anna M. Langstroth, sister of L. L. Langstroth, who died in less than a year afterward, and without offspring; he did not marry a second time.

Although Mr. Malin's tastes did not incline toward medical studies, he showed great interest in the treatment of the insane. As the result of his observations, he presented to the Board of Managers, in 1828, an article on the necessity of providing a separate asylum for the insane; and, again, in 1834, a paper on employment of the insane. Mr. Malin's views possessed so much originality and force as to lead the State Committee on Lunacy to publish these papers in its annual report for the year 1884. Copious extracts have also been made from these papers on another page of this history.

Mr. Malin was buried August 5, 1887, in the Woodlands Cemetery, Philadelphia; and his collection of historical and Bohemian books have a permanent resting-place in the library of the Moravian Brethren's Church, at Bethlehem. His portrait is in the hall of the Hospital, just at the entrance of the office where he lived for so many years.

[Perhaps our readers wonder what the life of such a man, however good and noble, has to do with bee-keeping. As prepared by father Langstroth it seems to be a sort of introduction to a very important old letter on a subject touching one phase of bee-keeping upon which comparatively little is known. The letter was written to Mr. L. long ago, as you will see; and as it has never seen the printed page before, I am sure it will be read with interest now. But before I give you Malin's letter I will here give an extract from Mr. Langstroth's letter concerning it.—Ep.]

Dear Ernest:—Since I sent you Mr. Malin's letter I find that there is a very full discussion of the question whether the honey-bee was indigenous to this continent, by Prof. A. Gerstaker, of Berlin, who sent it to Wm. Wagner. This article was translated by Samuel Wagner from the German, and published in Vol. II. of the *American Bee Journal* for July, 1866. Mr. Malin's letter to me was written in the fall of 1864, and antedates Gerstaker's essay; still I think that you will do well to publish Malin's letter; but I thought it only right to call your attention to Gerstaker's essay.

L. L. LANGSTROTH.

Dayton, O., Aug. 1.

WAS THE HONEY-BEE INDIGENOUS OR NOT IN THIS COUNTRY? A CAREFUL REVIEW OF ALL THE EVIDENCE.

PHILADELPHIA, Sept. 24, 1864.

Rev. L. L. Langstroth:—My Dear Brother:—I have consulted the paper of Dr. Barton, to which you re-

ferred me, and find that his conclusion, from all the evidence attainable in his day (1792), was precisely that to which my researches had conducted me; viz., that the honey-bee was not native, but was introduced from Europe. Had I known of Barton's essay it might have saved me some trouble, as he refers to, and quotes, sundry authors from "Purchas his Pilgrim," down to Bartram, which I had some trouble in hunting up. He, however, adds what I think a material fact as regards our inquiry; and that is, that none of the Indians occupying these regions had any original names in their languages for the bee or its products; and Elliot, when translating the Bible, was, in consequence, obliged to use the English names with Indian terminations. Subsequently, when the Delawares became acquainted with the honey-bee they applied to it their name for the wasp, and called honey by a name which signified the "sweet or sugar of the wasp;" and wax by one which meant the "fat, grease, or tallow" of the wasp.

I find that Barton's paper was prompted by one written by the Rev. Dr. Belknap, who contended that the honey-bee was native on this continent, in its southern portions, at least in Mexico and Cuba. I have read Belknap's paper; and have consulted the authorities he quotes, and am quite satisfied that he was wrong. Even he, however, admits that our insect was not found north of Florida, or the southern portion of Georgia. He also says, "There is a tradition in New England," the authenticity of which he was unable to trace, "that the person who first brought a hive of bees into the country was rewarded with a grant of land."

Further, Mr. John Josselyn (whose book I have also consulted), who was in New England in 1638, and again in 1663, in some account of his voyages published in London in 1673 thus speaks of the honey-bee: "The honey-bees are carried over by the English, and thrive there exceedingly."

The Rev. Mr. Heckewelder assured Prof. Barton that, although he had seen the true honey-bees wild in various parts of the United States at some distance from settlements, he was always assured by the Indians that these insects were not known in these countries before the whites began to settle them. Barton adds that it is very unlikely that these Indians could be mistaken on the subject, as they are by no means incurious observers, and are as fond of honey as the bears are.

Mr. Wm. Bartram, who traveled in West Florida in 1775, informed Barton that he was shown as a curiosity a bee-hive, the only one in that extensive country, introduced there from England when the English took possession of Pensacola in 1763. He had seen the honey-bee wild in East Florida, but was satisfied from his inquiries that it is not a native of the country.

Barton says, "The honey-bee was not found by the first settlers in Kentucky; but about the year 1780 a hive was brought by a Colonel Herrod to the Rapids of the Ohio, since which time these insects have increased prodigiously." Was this not the probable origin of those seen by your octogenarian friend?

The only authority quoted by Dr. Belknap for the probable existence of the bee in any part of the United States is the finding of a single pot of honey by the expedition of DeSoto at a place called Chiaba, on an island surrounded by shallow water, supposed to be on the upper part of the Mobile River, in Southern Georgia. I have referred to the narrative, as translated in Purchas, and find that this was the only honey seen or heard of by the expedition,

* This refers to information given me by an octogenarian clerk of the courts, residing, in 1857, in Hardinsburg, Ky. He recollected seeing honey-bees at so early a date in Kentucky that he had always taken it for granted that they were natives there.

I had read somewhere that, at the time the honey-bees were first introduced in America, the Norwegians were not troubled by the bee-moth (*Tinea mellonella*). As the bees in New England were not infested by this moth until 1805, it would seem quite possible that the first bees imported into New England might have come from some country where this pest was not known, and not from any part of the English Isles where it had been so long known. (See Dr. Kirtland's account of its first appearance near Boston, Mass., in my work, "The Hive and Honey-bee," 3d edition, page 240.)

L. L. L.

Yours affectionately,
S. L. Langstroth

which met with no bees. The granaries and store-houses of the natives were constantly ransacked by these needy Spaniards, from June, 1539, to July, 1543; and Barton pertinently remarks, "Had the honey-bee been a native of the countries which were the scene of DeSoto's villanies, the valuable products of this insect would have been frequently met with, and the bees, in territories pregnant with a profusion of nectarous plants, would have been seen very often, and in great numbers."

In addition to the above I may add that I have carefully consulted the narratives of many early travelers, from Father Hennepin down, and find no mention of honey having been met with on any occasion than as above stated. Had the Indians possessed honey would they not have set it before some of their guests? and would the latter, who mention every thing else they met with, have forgotten honey?

In conclusion, as no one pretends that the honey-bee was found in New England, as Josselyn, who, in 1638, must have known the first English settlers, and been familiar with their doings here, says expressly that they introduced our beloved insect, I think we may very safely dispense with the Norwegian theory of their introduction, and assume that the *Apis mellifica* is a valuable European insect for whose introduction and naturalization here we are indebted (as for many other blessings) to the people of the Mayflower, or their immediate followers.

WM. G. MALIN.

A PLEA FOR FIVE-BANDERS.

ARE THEY HAVING FAIR PLAY?

By A. Norton.

It seems to me that a great deal of hastily considered comment is being passed upon the five-banded Italians, and that undeserved denunciation is being heaped upon them. The fashion having been set, so to speak, by certain plain statements from the Roots, which in themselves are reasonable and moderate, it seems now that the majority are following the example only to outdo it, and that those who like the five-banders do not dare defend them. Let this race have fair play; and let all who find them as good as regular Italians (I don't see why they should be any better) give public testimony to that effect.

The claims coming from the Home of the Honey-bee, so far as I have seen them, are simply that some strains of five-banded bees originated in Cyprian and Syrian crosses, and are irritable, but that other strains are doubtless pure Italians, and as good as any. That is certainly all right. But now there are letters from certain persons in divers journals, claiming that these bees are not hardy; that they do not winter well; that the queens are not prolific; that they are not good honey-producers.

It may be safely stated, and depended upon, that you can not breed any points or characteristics into a race if you do not find a tendency that way to begin with; and you can not well breed a characteristic out unless there is originally a tendency to lack that characteristic to begin with. If the few years' breeding of this particular strain of Italians has already made them so inferior in so many ways, it only proves that the original three-banded parent race is so widely variable and unreliable in its characteristics that one can not depend upon them uni-

formly to be desirable bees. Even if a breeder should set out systematically to breed three-banded Italians down to inferiority as to honey-gathering, prolificness, and wintering, by purposely selecting the poorest in those lines, if the race is as uniform as we are led to suppose it to be, he should make slow progress because of not easily finding any very inferior stock to begin with. But in breeding five-banded stock the worst that can be said is, not that breeders purposely breed out good qualities, but merely that they think of nothing but color, and all other points pass unnoticed. But the mere fact that a certain queen's workers show more yellow than those of other queens, does not imply that they are either better or poorer in useful qualities than other Italians. They might incidentally be a little better or worse; but the main chances are that they would be about the same. Hence, in breeding from such a queen the stock could not deteriorate.

Now, taking the percentage of chances in all queen-breeding for five-banded bees, unless the parent three-banded stock is extremely variable and unreliable, I don't see how, in the few years so far past, the strain could have become materially better or worse than the regular stock. Does in-breeding cut a figure now with the large number of five-band breeders? How is it, then, with persons who advertise superior strains of three-banded stock (several such advertise in GLEANINGS, and hence we must assume their advertisements to be honest)? How can they perpetuate their superior strains without in breeding? If they mix in any of the ordinary outside stock, they must dilute and lose the superior quality of their own strains. One advertiser in GLEANINGS has bred Carniolans for yellow color, and yet has made an improved honey-gathering race of them. To change Carniolans to uniformly two or three banded bees is a greater change than that from three-banded to five-banded Italians. In-breeding and other detrimental influences seem, however, to be lacking.

While so many have dropped into the fashion of denouncing five-banders, I find some who praise them highly. Ira Barber, of New York, in a recent issue of the *American Bee Journal*, pronounces them, as the result of a few years' experience, superior to any others. (I should hardly expect them to be superior, however.) W. L. Coggsball, of Eastern New York, speaks highly of them. These persons have no queens to sell. I have had a limited knowledge of them; but that limited experience, so far as it goes, shows them to be gentle and industrious, with strong prolific queens. I find them working remarkably well in the scarce period of the California dry summer, late July, August, and September, and the queens keeping 12-frame hives, L. size, full of strong, active, yet gentle bees.

Looking among those who condemn them, I do not find any thing more striking than I notice in the difference between "Reports Encouraging" and "Reports Discouraging," where we find, from localities in the same State, and often quite near together, directly opposite reports. These differences are laid mostly to the season. But if any of the persons making them should have happened to be trying a new strain of bees, the latter would have come in for a large share of the blame or praise. Note what the majority of German bee-keepers say regarding blacks vs. Italians. From their preference we might think that nature, in breeding for three yellow bands, had produced an inferior race.

I do not go principally for fancy in bees. No bee-keeper, large or small, if he is sensible, will want less profitable bees because they look pretty. But if any one would not choose a handsome race in preference when the dollars and cents come in just as well, then he is lacking in a taste for the beautiful; and while we may not expect to cultivate taste in him, we are not expected to give it up ourselves.

I should like to have all, who can give facts to show that five-banded bees do not differ as to profit from three-banded, to send them in to add to what we already have, and see how much of a showing can be made. If these facts really can not be produced, then I will say, stop breeding them.

Monterey, Cal., Sept. 4.

[No publisher has tried harder to give the five-banded fair play than we. While I have not published all the adverse testimony, I have given, so far as I know, all that was in their favor. I myself at first felt quite kindly disposed toward them; but when I saw repeatedly their bad temper, their lack of hardiness—when, indeed, this was further corroborated by letters continually, with few exceptions, I felt that it was simply the duty of GLEANINGS to set forth the facts. You may show *why* yellow stocks should not be any worse; but good theory on this point can hardly offset real practical observation of what they are. I have letters from two queen-breeders who say that, as soon as they get rid of them (the five-banded) they will sell them no more. One of these men says he has tried stock from all of the best breeders, with results largely the same. Another blames us for not scoring the yellow stock more than we do. These men do not wish their names used, because they still have stock to sell.

I don't think myself that the ordinary stock of Italians is invariably uniform; but the point is right here: It is so difficult to breed real five-banded, that, in order to get four, and perhaps five, every *other* point is very liable to be sacrificed. It is not so easy to select out certain desirable qualities so that they may be plainly shown in the daughters of a breeding-queen. If the goal is hard to reach, is it not better that we take that which is the most desirable—that quality or qualities that will bring to their owner the most money? Color may bring the most money to the breeder; but to the honey-producer, nothing. I don't believe it is practicable to breed for every desirable quality at once. The most we can expect to get at one time, in bees, is energy, hardiness, and gentle-

ness, from a prolific mother. If the same time and thought were expended on these rather than on something that appeals to the eye, we should see more honey.

Of course, if we can have color at the same time with these other qualities, no one will be more pleased than I; but so far I don't see a very good combination that is from the progeny of the average run of yellow stock.

Later.—Since writing the above, neighbor Vernon Burt, who lives two miles north of us, reports that his five-banded were good honey-gatherers. We have a couple of colonies at our out-yard that have done well also. But if I am any judge these seem to be an exception. —Ed.]

SECOND-HAND SQUARE OIL-CANS.

HOW TO PREPARE THEM FOR HONEY; ALSO
SOMETHING IN REGARD TO THE
WATER WE DRINK.

By S. S. Butler.

I for some time have had in mind writing an article on cans, new and old, for storing honey. After a 20-years' experience, using thousands of cans, I am better satisfied with good oil-cans than to buy new ones. I have bought Lower California honey in new cans that were made of poor or lead tin, and so poorly put together that nearly all were in a leaky condition; but good oil-cans, always rejecting those that are rusty inside, being crimped at the seams, very seldom leak there, and, if well cleaned, I like better than the new ones made on this coast. I give 8 to 10 cts. for them. I melt off the four faucets by setting four cans, with the corners that have the faucets, together, putting a shovel of hot coals on them. A good worker can clean about 100 in a day by putting in a handful of unslacked lime in each, with 3 or 4 quarts of boiling water. After it is slacked, rinse it well, and afterward rinse out twice with cold water, washing them twice with lime. In that way it will clean them perfectly.

Having noticed your article on water, and in other places where you have spoken of nice cool pure spring water, I should like to say a word about nice pure spring water. I have made pure water a study for about 30 years, and have made up my mind that one can hardly ever find a spring or well of perfectly pure water. I have a fine spring. Two years ago I put in a cistern just where the spring was, going about 30 feet above, cutting off the several veins of water, and running them into the cistern. We dug down to hard clay, about 10 feet, through decayed vegetation, rotten roots, etc., that smelled almost as bad as a pig-pen. Pure water? Ugh!

I have invited people to come and see my simple apparatus that I have used for over 20 years on our stove to distill or condense our drinking-water—the only pure water.

We should purify the water we use outside, not inside our bodies. Our bodies being composed of over seven-tenths water, just as much as

we need pure air, just as much do we need pure distilled water, which is the only pure water. Water is the great cleanser, and is not pure, no matter from what source. Even rain water collects impurities and microbes as it descends. Water from lakes, springs, creeks, and rivers, has earthy salts, carbonate of lime, various minerals, decayed fish, worms, snails, and lizards, millions of microbes and animalculæ. The excrements of fish, worms, and the thousands of insects, birds, and animals, that live in and frequent the water, are found in it. A dead frog or rat occasionally comes up in the well-bucket. Do you think such water is healthful? All impurities are left behind when water is turned into steam, and that condensed or turned into water, and in no other way can one get pure water. There is no filter that will take out all impurities. My condenser gives us drinking-water while getting our meals.

Los Gatos, Cal.

[Friend B., your instruction in regard to using second-hand oil-cans will probably be valuable to many of our readers; and I am greatly curious to know about that home-made apparatus for getting distilled water. Can't you describe it, or make a rude picture of it so we can have it illustrated? In many localities I suppose such a method is almost the only one for getting real nice water to drink.—A. I. R.]

THE DARK AND BRIGHT SIDE OF APICULTURE.

THE "OTHER SIDE" TO THE DARK SIDE PRESENTED BY FRIEND DOSCH ON P. 737.

By J. P. Shaw.

In reading GLEANINGS last evening I noticed the article on page 737, written by L. A. Dosch, of Miamisburg, O., very discouraging indeed. Now please excuse mistakes, as this is my first writing. I live not quite three miles from Mr. Dosch, up the Miami Valley. Three years ago I started with one hive; increased to ten, but got no honey; wintered through all right. From six of those ten last year I got 280 lbs. of section honey; increased the other four colonies to 15. Starting in last winter with 21 colonies I came out in the spring with in fair shape—a loss of two colonies.

Now for this dry season. I started 12 colonies to working on sections, and got 400 lbs. of section honey from them, leaving plenty for winter. The other 7 colonies increased to 15 last year. With 6 colonies I got 280 lbs.; and my neighbor, with only a fence between our bees, got 10 lbs. from 7 colonies. I think there is a great deal in the management of bees. So you see this locality is not so bad after all. Sweet clover here is the main honey-flower. As dry as the summer has been here, it grew from 5 to 6 feet high, and the bees just swarmed upon it. I use the eight frame L. hive, and I

contract down to six frames at the commencement of the honey season, and feed a little in the spring at the right time. I do not think this locality so bad as friend Dosch does. I guess I shall have to go down and buy him out.

West Carrollton, O.

J. P. SHAW.

[A difference of only three miles sometimes makes quite a difference in the honey; still it is not improbable that your superior management accounted largely for the difference in results. When a man is utterly discouraged, as friend Dosch is, he is not apt to put the best foot forward; in other words, use the best and most economical management.—Ed.]

ISRAEL'S CROSS-EYED BEES.

FOUNDATION IN SECTIONS VS. FOUNDATION IN BULK OF THE SAME AGE; AN INTERESTING AND VALUABLE EXPERIMENT.

By J. P. Israel.

I have for many years enjoyed the reputation of being the boss idiot of Southern California. No man so far has questioned my title or contended for the championship. But the bees this year have stripped me of my honors, and I have yielded up to them the belt so long and honorably worn. This is how they went about to do it.

When the time came, in the spring, for putting on sections, I found I had more than enough, with foundation already in them, to cover my whole apiary. This foundation had been put in these sections more than a year before; and on our failure to get honey in 1894 the sections were stored away. I thought I was fortunate in being all ready for the honey crop, and piled on the sections liberally. Ten days afterward I looked over them to see how they were building. *Every* colony that had gone into the upper story was building *crooked*! Their favorite way of building was *crosswise* the sections, as if they wished to bind them together with iron bands. Crosswise, cat-cornered, around the corner and back again they came. But the foundation, they would not touch. It was pure wax, made in this apiary, and run out by myself. What could be the matter? I sat down on a hive to meditate.

"Here," said I, "is a whole apiary gone mad crosswise! I will get at the true secret of this state of affairs, even if it takes me all summer."

I got my microscope and examined the bees, and, lo! the secret was out. The whole apiary was *cross-eyed*. I stood aghast with astonishment and consternation. Could it be possible? Oh for a carload of "them fellers" from the East who know it all, to tell me how to breed back again to straight-eyed bees! I could see through the crooked part of it very plainly. When a bee got on to a piece of foundation to draw it out, being cross-eyed he was actually not there at all, but around the corner, build-

ing a cross-section between the two sheets of foundation. Don't you see it plainly?

But to make assurance doubly sure I tested my microscope by a first-class instrument, and found that it was *my glass* that was *cross-eyed* instead of the bees. So I had to seek a solution of this extraordinary freak in another direction. This foundation had been suspended in the sections for more than a year. Might it not, in that time—being in single sheets—lose some of its essential oils, and be unfit for the bees—too hard and flinty? I had more of this same foundation (in bulk) which I believed to be good. So I took the sections off the whole apiary, and replaced the foundation with that which was kept in bulk (but of the same lot), and the bees went at it and built as straight and beautiful combs as ever.

Now, to me this proves two things: 1. Foundation suspended in sections will not keep a long time without losing some of its "internal arrangements" which are necessary for the bees. 2. Foundation in bulk will keep a long time, retaining all its elements intact which are required for its successful working into comb. So you can notify that "carload of fellers" not to come all at once, but three or four abreast.

DO BEES EVER GATHER WHITE-SAGE HONEY EXCLUSIVELY?

Well, Rambler has knocked all my ideas in regard to white sage into pi. If there is one single spot in all California where bees gather honey from the white sage exclusively, I did not know it. It must be a poverty-stricken place for other flowers, for the bees *will* work on other flowers while they are working on the white sage. It is different with the black. They will touch no other flowers while the black sage remains in full bloom. I did not believe that any man ever secured a single pound of pure white-sage honey in all California or any other place. The black sage comes out first, and, while that lasts—although the ground is carpeted and the chapparal is interwoven with flowers—the bees will stick to the black sage. Thus we get the first half of our crop from the black sage. Then the bees change to the white sage and the thousands of flowers that bloom with it. The consequence is, that the honey is always a mixture—amber, some light and some darker.

But Rambler has found a place away back in the Sierra Nevada Mountains where the bees revel in the white sage, and the white sage alone. How I should love to taste it and compare it with pure black-sage honey!

Escondido, Cal.

[Experiments made recently by the Michigan experiment station, as well as the testimony of competent bee-keepers, go to show that old foundation is as good as new. But I could not understand *why* a few observers equally competent should think it was not; but in the light

of your experience I think I understand. The last mentioned, those who reported adversely regarding the old foundation, tested it probably when it had been a year in the frames or sections before giving it to the bees to be drawn out. Of course, being exposed to the free circulation of air it would dry in a way that the same article in the bulk would not. If this is true, and it certainly is reasonable, friend Israel has called attention to a valuable fact worth considering. I should like to hear from others on this point.—ED.]

RAMBLE 141.

LOST IN THE WEED-PATCH.

By Rambler.

After passing Tulare we were again in an uninhabited country. Away to the east, the Sierras present a dim outline against the horizon; to the west, the Coast Range presents much the same appearance; between them, a broad prairie at least 100 miles wide, many portions of it having all of the qualifications of a desert. The portion we are now passing over is dry, parched, and not a tree or blade of green vegetation to relieve the monotony.

O solitude! where are the charms
That sages have seen in thy face?
Better dwell in the midst of alarms
Than reign in this horrible place.

To my notion, solitude can be endured and even enjoyed where there are running brooks, trees, rocks, and some animal life; but out on a barren plain, please excuse me. Little railroad stations loom up occasionally. We are just about out of sight of one, when away ahead of us another begins to rise as it were out of the desert. Here at the little stations of Poso or Kimberlena would be just the locations to start experimental queen-rearing apiaries. The isolation would be complete, and the fertilization of the queen with any choice strain of drones could be easily controlled. I would suggest that the new woman, unmarried and of uncertain age, here organize a colony as outlined in Tennyson's "Princess," where dogs, cats, pigs, etc., are all females, and the death-penalty is the fate of all intruding males. I am afraid, however, that the scheme would not work; for in queen-rearing, drones (the male bee) would have to be tolerated. My suggestion, though, is worth acting upon so far as queen-rearing is concerned, and I hope some one will act, and reap fame and fortune.

It was upon this broad and barren plain that we had the pleasure of witnessing that curious natural phenomenon, the mirage. All along the distant western horizon there appeared a narrow belt that glistened and shimmered under the mid-day sun, and for a time we were deceived with the idea that we were in sight of the shining surface of a lake or river. The same appearance soon presented itself in our

rear, and beyond the shimmer we could see the far-away stations we had passed in the early hours of the day, which had been some time out of sight; and then it dawned upon us that we were in the land of the mirage. We could seemingly look so far away that it appeared like a beautiful fairy-land; and the dancing of the sunbeams seemed like the flitting to and fro of the fairies. It was a pleasure for me to imagine such a land. I was lost in the contemplation of its beauties; and, indeed, if this were but the vestibule of heaven I longed to be there.

My intensely practical companion, however, thought we'd better move on, and my airy ideas came down with such a sudden thud when I thought of his ten angels that my tongue refused utterance until we had entered the thriving town of Bakersfield, and the mirage had disappeared. Quite a number of bee-keepers live within trading distance of this city; and the conditions for honey production are much the same as we find further north in Tulare and Fresno Counties. We could not hunt up these good men, for we were now upon a genuine stampede for the south; cool nights, threatening skies; and still between us and our home the frowning Tehachapai Mountains, and the little less frowning San Fernando range.

We arrived in Bakersfield Saturday afternoon; and, after laying in a new supply of provisions, we resolved to push right along and travel all day Sunday. We were aware that "a Sabbath well spent meant a week of con-

ed ourselves by a weed fire, and in our sleep dreamed of weeds.

Soon after breaking camp Sunday morning an unforeseen circumstance presented itself—Reina went lame, and our progress the rest of the day was extremely tedious. The drive during the forenoon was relieved by seeing now and then—more often then than now—a vacant cabin. At one place among the weeds we were surprised to run across a small apiary of about 20 colonies. The bees were at home, and had a committee out to receive company in their aggressive way; but the cabin near by was vacant. We knew it was vacant, because we could see through it about as easily as we can see through an old-fashioned Eastern corn-crib, and thus a weed-patcher lives. We did finally find a good dwelling with an occupant, and he gave us the gratifying intelligence that we had traveled twelve miles further than necessary. He kindly pointed out the road which we could see for twenty miles ahead of us, leading toward the Tejon (Tá-hone) Pass. Not a rod of this country is interesting; and if we were to choose a route for scenery it would not be in the upper San Joaquin Valley.

Water is a valuable element here, and is plentiful after digging very deep into the earth. An Italian weed-patcher loaned us the use of his well, and gave us a lesson in hydraulics. A large coil of rope lay upon the ground; the end ran over a pulley to the bucket. When bucket and rope, after a long paying-out, had disappeared in the well, our Italian weed-patcher pointed to a path that led out toward Bakersfield, and told us to take the end of the rope and travel that way, and pull. He was to fire a gun to let us know when the bucket was up. Wilder and I started for Bakersfield, 20 miles distant, with the rope over our shoulders. We traveled some time conversing pleasantly by the way, and imagined that we looked like the pictures of Samson laboring under the gates of Gaza. After a while we began to speculate upon the nearness of that bucket to the surface.

It was heavy tugging; all of a sudden the weight became so laborious that we desperately tied the rope to a weed and returned to the well. When we took in the situation we were just mad. That miserable Italian, while waiting for the bucket to arrive, went to sleep. We shook him up lively, and, after yawning and looking at his well, and seeing the water spilled all around, he went tearing mad too.

"Zee here!" he shouted; "yous alfiert Americanos, yous pull pull. Zee here! gone pottom of zee well; pull up; py gar, yous pay zee hunner tollar—zee hunner tollar, I zay."

Now, we had not the remotest idea of pulling:

"WE STARTED FOR BAKERSFIELD."

tent, and a joy for the toils of the morrow;" and in all of our long journey we had traveled on Sunday only where the necessities of feed for our horses compelled us to do so for a few hours. This time, soon after passing our Sunday-travel resolution, we left Bakersfield, and, among the multitude of trails across the plains, we easily succeeded in getting upon the wrong one. Our next mishap was to get directions from a drunken teamster who sent us into what is locally known as the weed-patch, and still further off our route. After toiling through the sand until long after dark we camped among the weeds; boiled our coffee, and warm-

up the bottom of his old well; but this being a day of untoward events we expected almost anything to happen, and were not surprised. We felt guiltless in that respect, for he was to blame for going to sleep, and we so convinced him.

Now, if the foregoing seems to be something in the line of an allegory, it goes to show the many petty phases in which an Italian will grasp to turn a dollar to his own benefit. Those who have never met an Italian only as an organ-grinder, as we know them in the East, do not understand what thrifty people they are. The climate of California, so like that of Italy, attracts thousands of them to this coast, and they will settle down in such a place as the weed-patch, or in a worse place, where an American would starve, and make a living and accumulate some wealth besides. Their methods of getting the dollar are not altogether

hired men, he was entertaining a convivial Irishman who also had bachelor quarters in the pass beyond. I would have taken this genus *homo* to be a Scotchman; but Irish he said he was, and Irish it is. He entertained us with song and story, and it required but little observation to teach us that he was a bookish man, a lover of nature, poetry, and his fellow-man. In the morning, when he departed for his abode, he informed us that our route lay directly past his door, and he gave us a cordial invitation to enliven the lonely hours of the evening in his cabin.

We were now in the extreme southern and upper end of the great San Joaquin Valley. From Merced we had followed it continuously for nearly 200 miles, and no one can ever appreciate its greatness until he travels through it with a camping-outfit. There is room enough here for a grand empire. We can drop into

RUINS OF FORT TEJON (TAHONE).

honorable at all times. The Italian woman is as sharp as the man at a bargain and much sharper with the tongue.

Whatever might have been our vexations during the day, we were most fortunate that evening in finding a camping-place near the cabin of a young American bachelor rancher. Here, instead of going several miles, more or less, into the ground for water, the precious fluid was drawn several miles in barrels, and we were able to get a supply without much vexation on our part.

In the evening we were made welcome to the warming influence of the cabin-stove. We have found that a large number of bachelor ranchers outside the ranks of bee-keepers usually blacken their floor and mop their stove; but this young American reversed the order, and the cheerfulness of his cabin was that much enhanced. Besides his two bachelor

this valley the States of Maine, New Hampshire, and Vermont, and then have some room to spare. We leave it now, pleased that we have been permitted to traverse its waste places, its fertile lands, and its populous cities. As indicated around Selma, Hanford, and Bakersfield, the possibilities for honey production are great. In the near future, under the magic influence of irrigation, hundreds of thousands of people, and among them thousands of bee-keepers, will here find prosperous and happy homes.

We leave the great valley through the Tejon Pass, and encounter in its narrow defiles the ruins of old Fort Tejon. In early days this was an important strategical point; but now, in the poetical language of our Irish poetical friend,—

We stand to-day amid the ruined walls

Of what was once the famous Fort Tejon.

Where lovely women graced the princely halls;
 Where brave men answered to the bugle-calls;
 Where war-steeds chafed impatient in their stalls;
 Scarce aught remains but scattered brush and
 stone.

MANUM'S LONG-DISTANCE MAILING-CAGE.

THE USE OF HONEY IN COMBINATION WITH
 CANDY.

By A. E. Manum.

I mailed you a few days ago one of my long-distance mailing queen cages for your inspection and criticism. I was led to do so by receiving two of *your* long-distance queen-cages, already provisioned, addressed, and stamped, with a request that I use them for mailing two queens to one of your customers in Australia.

My first thought was, upon receiving your cages, that I would not use them, but would use mine instead; but upon further consideration I concluded to use them just as you had them prepared, inasmuch as I had an order for queens direct from Australia. I thought it a grand opportunity for me to *test* the merits of the two cages. One of the queens sent in your cage was the same age, and an own sister of the one sent in my cage, and, to all appearance, the two queens were alike. I am thus particular in giving you these points, that you may join me in watching results.

The reason why I hesitated to use your cage was because I had tried the same cage before for mailing queens to Australia, and failed in my attempt to get queens there alive; and as orders for queens continued to arrive from that source, I decided to attempt the construction of a cage in which I could safely mail queens to the distant land above mentioned; and the cage I sent you is the result of much study of the requirements of the bees while on so long a journey. I took into consideration the changes in temperature they would necessarily experience on that long journey.

You will notice that, in the center of the cage, there is a compartment into which a small piece of comb honey is placed, there being 6 openings, or passageways, to this compartment, so that the bees can enter it from four sides, and partake of honey whenever they desire. There are also four places—two at each end of the cage—for the reception of the ordinary (sugar and honey) queen-candy, which I make as hard as possible with my hands.

My object in using honey in this long-distance cage is to give the bees a small ration of their natural food, which I anticipate will last them a good portion of the journey; but should it fail to do so they have the candy to fall back on. The honey is placed in the center of the cage in order to balance the cage, and also that the bees may have access to the honey from each chamber as well as to the candy; hence they can partake of either candy or honey from whichever chamber they may happen to be in. There are also four passageways through which the bees can pass from one chamber to the other. Each chamber is $2 \times 1\frac{1}{2} \times \frac{3}{8}$ inch, making ample room in each chamber for 75 or 80 bees, and food enough in the cage to last at least 60 days. The outside dimensions of the cage are $7\frac{1}{4} \times 2\frac{1}{4} \times 1\frac{1}{8}$ inch, and it weighs, when ready to mail, 5 oz., the same as your cage.

Now in regard to your cage, I consider the *one* chamber too small for the number of bees I consider desirable to accompany the queen on so long a journey, since it often takes 40 days for them to reach their destination. And, again, in your cage the bees are obliged to subsist entirely upon candy. I am aware that yours is much the cheaper cage to make; but when we warrant the safe arrival of queens, it is to our advantage to use the cage that will carry the greater number through safely, because it would require many cages to equal the loss of one queen. And, on the other hand, if we do *not* guarantee the safe arrival of queens, it is to our advantage to look after the welfare of our customers. It always gives me great pleasure to receive cheerful letters from my customers, as I am sure it does you.

Bristol, Vt.

[This cage, I must acknowledge, is a better one than the one we have been using for the same purpose. Indeed, I was so well pleased with its general construction that I made arrangements with friend M. whereby we could manufacture and use it for our own business.]

Instead of being made of a solid block bored out, it is made of strips of wood dovetailed together as shown. This construction secures at once both lightness and strength—very important factors, by the way, in an export mailing-cage.

Like our export Benton it has holes at each end to take the prepared candy food, and in addition has a little chunk of good sealed honey secured in the center. This was, as I judge by the sample before me, cut out the required size to fill the oval hole in the block at E, and was then given to the bees just long enough for

them to lick up all the drip. It may then be slipped into the block, and secured to the block E by means of a little melted paraffine or wax, painted along the edges of the comb in contact with the wood.

B is paraffine, or waxed paper, to cover the candy A, and is the same idea that is used on our export Benton.

Of course, the use of sealed honey in queen-cages is very old; but how often it has happened that we have gone back to some *old* things! In this case we combine a new and an old idea together. If the candy fails, the honey is at hand to relieve the situation.

A year ago one of the friends in Australia, I forget his name, urged the use of a little piece of comb honey, as he had tried it with success. Well, Manum, in this country, got ahead of us, and I guess has made a better job of it.—ED.]

THE RIGHT KIND OF FRAMES.

THE V EDGE TO HOFFMAN FRAMES; SELF-SPACING FRAMES; OBJECTIONS TO THE STEPHENS SPACER; FURNITURE-NAILS NOT ENTIRELY SATISFACTORY; WIRE FINISHING-NAILS PREFERRED.

By Dr. C. C. Miller.

While the controversy has been going on as to the proper size of hive, I've been trying to settle on a frame—not the *size* of frame, for the size $17\frac{1}{2} \times 9\frac{1}{2}$ is so well established that I haven't thought worth while to consider that further; but there hasn't been the same stability as to the kind of frame. Just as something seemed to be coming generally into use, some change would be made, and I might as well be picking out all the good points I could find in order to unite them in a frame that would satisfy me at least partially.

At first I thought I liked the Hoffman frame with the shouldered top-bars, and didn't see the sense of the Medina people in so soon making the change to the V-edged end-bar. But on longer use I found in actual practice that there was such an accumulation of propolis that each frame was practically $\frac{1}{16}$ of an inch wider at the shoulders. Nothing so very bad in that if the hive had been wide enough; but as it added half an inch to the total width of eight frames, they were so crowded in the hive that it was a difficult job to get out the first frame. I'm not sure that it wouldn't be a good thing to have the inside width of a hive $12\frac{1}{2}$ or more, instead of $12\frac{3}{8}$; but I've always tried to keep as closely as possible in the beaten track of that which is most generally in use.

The Hoffman frames, as now made by the A. I. Root Co., have the advantage that, no matter what the accumulation of propolis, by squeezing hard enough and long enough you can get them into place, because that V edge cuts its way through the soft propolis. But they have the disadvantage that such an amount of propolis is none too easy to pull apart.

Another thing about all frames that are spaced only a portion of the way from the top, is that, when you lift a hive and look under, you

are surprised to see the irregular spacing of the bottom-bars. To obviate that, the frames should be spaced at the bottom as well as at the top.

As it seems pretty well settled that the distance between top-bars should be $\frac{1}{4}$ inch, I know no good reason why the same distance should not be preserved between end-bars and bottom-bars. With the usual wider space, there is some trouble with brace-combs.

By spacing at bottom as well as top, it is possible to have a much smaller point of contact between the frames; and the smaller the point of contact, of course the less trouble with propolis. So I had some frames made with top-bar, end-bar, and bottom-bar all the same width, $1\frac{1}{2}$ in.; thickness of top-bar $\frac{3}{8}$. If there were no other reason for this thickness, there is reason enough in the fact that it keeps the brood-combs and the sections that much farther apart; and when the sections are too near the brood-combs they are darkened thereby. End-bar $\frac{3}{8}$ thick; bottom-bar $\frac{1}{4}$.

I studied a good deal on the matter of spacers. The Stephens spacer, with its two nearly cutting edges at right angles, gives the smallest point of contact of any thing I have seen, and smallness of contact surface is the especial desideratum to fight propolis. An objection to the Stephens spacer, however, is the fact that it spaces the frames from center to center at a fixed distance; whereas the thing desired is to have an exact space *between* the frames. One of these would secure the other if all frames were made exactly true; but, unfortunately, there will be variations in thickness; and a variation of $\frac{1}{16}$ in. in the thickness of top-bars may cause the distance between two top-bars to vary anywhere from a space of $\frac{1}{8}$ inch to $\frac{3}{8}$.

I wanted something, much on the principle of the Stephens spacer, and searched Chicago twice to find some kind of staple that would project $\frac{1}{8}$ inch above the surface into which it was driven, two antagonizing staples being at right angles to each other. The nearest I could come to it was the common double-pointed tack; but this could not be driven into the wood without splitting it. The only fear I had about an arrangement of this kind, providing I could get something that would drive without splitting the wood, was that each staple, being only $\frac{1}{8}$ in. distant from the opposite frame, the bees would fill that $\frac{1}{8}$ in. with propolis. But that would be nothing like the amount of gluing done with the Hoffman frames.

As a temporary shift, I used wire finishing-nails, knowing well the danger of these nails catching in the adjoining frame. I also used some furniture-nails. The latter I don't like, upon trial, as well as I expected to. While they do not catch as do the finishing-nails, the bees feel it their duty to fill out with propolis all the space between the whole of the nail-head and the opposite frame. As a result it takes quite a

pull to get the two frames apart. The heads of the wire finishing-nails are only about $\frac{3}{32}$ across, so that very little propolis is put around them, and a very slight pull brings them apart. I like them very much better than I expected to.

In the under side of the top-bar is a saw-kerf $\frac{3}{32}$ wide and $\frac{1}{4}$ deep, to receive the upper edge of the foundation. The frame is wired in the usual manner with four horizontal wires. The foundation is cut just the proper size to touch each end-bar, and $\frac{1}{16}$ deeper than the inside depth of the frame. The upper edge of the foundation is inserted in the saw-kerf, and then allowed to settle down on the bottom-bar before the wires are imbedded in the foundation. After the wire is imbedded, a strip $\frac{3}{4}$ or 1 inch wide is cut out, all but about an inch at each end. The lower edge of this strip is about $\frac{1}{4}$ inch above the lower wire. In this way I have frames filled solid with comb; but for some reason that I don't understand, some of the combs bag a trifle at the lower wire—nothing very serious, however.

I've only a hundred of these frames in use; and before I get any more I'd like to be told what change to make in them. Advice is solicited from all quarters. You will probably believe that I don't want to be in too much haste about getting a large number of these frames in use at once when I tell you that I have 500 loose hanging frames and about a hundred less Hoffmans, all wired ready for use, and I'd like to know a little better what I want before getting ready another lot.

Marango, Ill., Aug. 11.

[You are right in considering the size of frame as pretty well settled. While I have been very well pleased with the Hoffman, I know there are some who would prefer something a little less fixed when propolis is bad in the fall of the year, or when the atmosphere is a little chilly, making bee-glue hard and stiff.

The objections that you have named against the Stephens spacer holds good; and there is still another and a more important one—the expense.

Finishing-nails for wires are used by some bee-keepers, but have never become very popular. A serious objection is their obstruction to the uncapping-knife, and their interference to the extractor caused by the nailhead catching in the meshes of the wire cloth in inserting and removing the frames. There is still another objection; and that is, if the nail itself is not crowded deeper into the frame in which it is driven by use, its head will in time gouge a hole in the other frame. Either would destroy equal spacing; and the great feature of the Hoffman frame is that you can crowd on one frame, and push as hard as you may, you can not destroy the exact spacing, because the wide perpendicular edges are sufficient to stand the strain. Suppose, for instance, that you remove a couple of frames from the center of the brood-nest. It is the fall of the year, and the four outside frames next you, we will say, are stuck down. It requires a little leverage to crowd them over *en masse* to fill up the space. Whatever spacer we have should be one that will stand a hard squeeze.

If you must have something different from

the Hoffman, I am inclined to the opinion that something on the order of a furniture-nail would be far better, notwithstanding your objection. You can not drive it too deep, and it will stand the squeeze. If the nails you tried with rounding points are not just the thing, how would those do that are perfectly conical?

As some of our newer readers may not understand the furniture-nail spacer, I introduce an engraving with the description that appeared in GLEANINGS for 1890, page 481.

As so many are suggested, I'll tell you one I'd like to try, but, oh dear! I'm so crowded in the busy season that it isn't likely at all I can try it; but some one else may. I think it may be very old. Get a furniture-nail whose head projects $\frac{1}{8}$ of an inch, or a square block of wood of the same thickness, and drive into one side of the top-bar at one end, just over the end-bar. Put one on the *opposite* side at the other end, and your spacing is complete so far as the frames are concerned. The dummy must be treated in the same way (for I imagine a dummy is important with fixed distances), and on each side of the hive must be a spacer where there would be one if a frame came in place of the side.

VERTICAL VIEW OF HIVE, DUMMY, AND THREE FRAMES WITH SPACERS.

To make it more satisfactory, I think a spacer should also be put about half way down the end-bar.

C. C. MILLER.

The heads of these furniture-nails are $\frac{5}{16}$ or $\frac{1}{4}$ inch deep, depending, of course, on the width of the top-bar. They are just deep enough to reach from one top-bar to the next; and as they are put on alternate edges, as shown in the diagram which we reproduce, exact spacing will always be secured.

The advantage of such a spacer is, that it can be attached to frames already in use. It can be used or not, as preferred. They are cheap, and will space top-bars just exactly the same distance apart, no matter whether they are sawn exactly the same width or not. As this spacer was proposed away back in 1890, I should like to hear from those who have used it since that time; and if so, how they *still* like it; if discarded, why discarded.—Ed.]

PREPARING THE BEES FOR WINTER.

Question.—Will you tell us something in GLEANINGS about how to prepare our bees for winter—when it should be done, and all about the matter?

Answer.—Well, this is a pretty big "dose" for once, and more than can properly come into one issue of GLEANINGS; but I will do the best

I can; and if space will not permit me to say all I should like to, I may try again in some other issue. Many seem to think that the latter part of November or December is early enough to prepare bees for winter; but some of our best apiarists have learned that the best results in wintering can be secured only when preparations are begun early in the season, so that the inside of the hive need not be disturbed after cold weather arrives. Therefore all colonies are to be looked after as soon as the honey-harvest is over, to see that they have good queens, and that there is plenty of brood in all stages, for this brood is to produce the bees that are to live through the winter months; and if, for any reason, there is not plenty of brood at the end of the honey-harvest, it is easy to tell what the result will be the following spring. If any colonies are found that have been and are short of brood, the queen should be changed for a good one, and brood from those which have an abundance be given them so that they can build up so as to be sufficiently strong in bees before cold weather sets in. If by any means, after all our precautions, the 20th of October finds us with weak colonies, they should now be united; for it is useless to attempt to winter very small colonies unless we have some special place to put them in, which has proven in the past to be sufficiently equal to the wintering of such colonies. Again, we wish to know that all have honey enough, of good quality for winter. Good quality in honey has as much to do with the safe wintering of bees as any one thing that can be named; and he who does not pay any attention to this matter can not expect to succeed. But what is good quality in honey? may be asked. If we look to nature for an answer, we shall find that, as a rule, the honey which a colony left undisturbed has in store, is that which has been in the hive long enough so that it is thoroughly ripened, having that rich, smooth taste we all like so well. Now, such honey as this can not be gotten, just at the close of the season, where the extractor has been used till the very last thing, as many novices persist in doing, leaving only the thin watery stuff which comes at this time of the year for the bees to live upon. In my opinion, upon the injudicious use of the extractor is chargeable much of the loss of bees in winter; for where we hear of large yields of honey taken with the extractor late in the season, we almost always hear of a corresponding loss of bees by the same parties the next spring. To overcome this difficulty it is better to set aside enough combs of thoroughly ripened sealed honey during the season to winter our bees; and then, when the honey yield is over, exchange combs with the bees, extracting all that is left in the combs taken from the bees if we so desire. In this way we are sure that the bees have such honey as they

ought to have to winter on. This applies only to those who are prone to extract too closely during the season; but it is a good plan to work a few colonies for such combs of thoroughly ripened honey to be used in case of emergency, no matter how the bees are worked.

Another reason why we should not put off preparing the bees for winter till cold weather comes, is that, if we do this, they can not well get their winter stores near and around the cluster in time for them to settle down into that quiescent state so conducive to good wintering, prior to November 10th or 15th. To arrange these stores, and properly prepare them, requires warm weather; hence all will see the fallacy of putting off caring for them till cold weather arrives. To be sure all have the desired amount of honey, there is only one certain way to do; and that is, to open the hives and take out each frame and weigh it, after having shaken the bees off from it. Next weigh a frame of empty comb, or several of them, so as to get the average weight, which, when deducted from the weight of those in the hive, will give the weight of the honey. If it is found that there is 25 pounds of honey, said amount is sufficient for winter where the bees are to be wintered outdoors; or if 20 pounds, that will do very well where bees are wintered in the cellar. If less, the deficiency must be made up; if more, it can spare some to help another colony which may be short. In this way go over the whole yard, equalizing and giving stores as is required, till all have the required 20 or 25 pounds.

"But," I hear some one say, "this is a fearful job to shake the bees off from every comb, and weigh it." Well, so it would be if done with each colony; but you will have to do this with only one or two till you get the right conception of just how much honey there is in each frame by simply looking at it and holding it before you, when you can count off the number of pounds almost to a certainty. However, you will have to weigh a few, if you have never practiced this plan, to give you the necessary training required. I can count off combs of honey so as to rarely vary one pound on the whole hive, and yet do it as rapidly as I can handle the combs; and when the apiary is thus gone over, there is a certainty about it which gives the apiarist a great advantage over any other mode of procedure, which can be little above guesswork at best. If there is not enough honey, after all are equalized in the apiary, to give sufficient stores to all, then draw on those combs you have set aside for emergency; and if not enough of these, then you will have to resort to feeding. As I go over the hives in this way I carefully note the quantity of bees, age of queen, amount of pollen in the combs, etc., which is jotted down on a piece of honey-section, this piece being left on

top of the hive, so that the next spring I can tell just what was in each hive the fall before, so that in case of loss I can form some idea of what occasioned it. This little piece of section also helps me in deciding what queens to supersede during the next season, for on it I keep quite a record of when the colony swarmed, how much honey it made, etc. After having the bees prepared as above, they are to be snugly tucked up in their chaff and sawdust cushions, at any time before the 20th of November, when most convenient, when they are to be left undisturbed till spring or placed in the cellar, according to where we winter our bees.

blossoms extend up and down the stalk. The seed from it is in a hull that curls up like a snail; and those hulls, or pods, will extend up and down the stalk from two to four inches.

Let the hive discussion continue, by all means. I have summed it up as follows: where the honey-flow comes late in summer I think the large hives, say 10-frame L., the best. Where the honey-flow is early I should prefer the 8-frame. I have tried two 8-frame L. hives, one on top of the other, but I don't like it. It is too unhandy to work with, and doesn't do as well for comb honey as the single 8-frame.

J. A. TAYLOR.

Wynnewood, Ind. Ter., Sept. 13.

THOSE NAUGHTY FIVE-BANDERS AGAIN.

Possibly you would like to know how I came out on the \$5.00 golden five-banded queen I got of you last year in June. I built her up with a fine swarm, and plenty of honey. I put the strong colony into our dry cellar in October. The swarm lived till January, then all dwindled away. Thus ended my nice tender bees. No more five-banded queens for me.

Canova, S. Dak.

L. R. HILLMAN.

LIFE-MEMBERS TO UNION.

In the matter of uniting the Bee-keepers' Union with the N. A. B. K. A., I am in favor, and would have not paid \$10 to become a life-member of the latter if I had not understood that it was to make me also a member for life of the Bee-keepers' Union.

O. R. COE.

Windham, N. Y., Sept. 21.

[Yes, some provision should be made by the committee to include life-members in the new organization.—Ed.]

12-FRAME LANGSTROTH HIVE.

Keep the hive question going. You remember you made for me last winter ten 12-frame hives. I have been using them with an equal number of 8 and 10 frame hives this season, and the results so far are about equal—about 70 lbs. per colony of comb honey. The 8 and 10 frames require a little more work than the 12. This has been an average season in this locality. Last year was a poor one, and all the surplus I got was from 12-frame hives. I am of the opinion that the queen is the greatest factor in the matter of surplus, all else being equal.

Bristol, Tenn. M. D. ANDES.

ALFALFA; HOW IT RESEMBLES RED CLOVER.

In the Sept. 15th issue of GLEANINGS you ask for a sample of alfalfa. I will describe it so any one can tell it. It has a stalk and leaf similar to red clover; but it is smaller, and the

RAPE AS A HONEY-PLANT. ALSO FOR CATTLE, HOGS, AND SHEEP.

I received 1 lb. of rape seed from you last spring, and sowed perhaps a third of it on poor sandy land, and my bees just fairly swarmed on it for fully one month; and I also cut it up to feed my hogs on, and they ate it in preference to corn. I had the rape along my pasture fence, and was compelled to cut up all near the fence to prevent their reaching through to get at the rape, and my cattle were not short of pasture either. I think it is one of the best honey-plants I ever saw, not even excepting white clover. I do not know how much honey my bees gathered from rape, simply because I was running them for increase this year; and I thrashed $2\frac{1}{2}$ bushels of seed.

A QUEEN WHICH I RECEIVED FROM JOSEPH NYSEWANDER, DES MOINES, IOWA.

Mind you, this is no ad't, for Mr. N. knows nothing of it. I received a golden queen from him, and on the 28th day of June she laid her first eggs. She was introduced to a poor miserable weak colony of bees, and she filled it up to a good colony. This is an eight-frame hive. She got so strong I feared she might swarm, so I took her and two frames of brood, and put her into a ten-frame hive, and she has also filled it and given me 28 lbs. of nice section honey. Now, if we can have such queens as this, then I say we must have larger than eight-frame hives. Perhaps I might add, that I had plenty of old combs, so they had none to build.

Cumminsville, Neb., Sept. 25. JAS. PRATT.

[We are very glad indeed to get so good a report from rape, for I have been feeling that it was a rather neglected plant. We have plenty more of the same kind of seed furnished friend P., which we can supply at the following reduced prices: 1 lb., by mail, 15 cts.; 10 lbs. or over, by freight or express, 6 cts. per lb.; 100 lbs., \$5.00. With favorable weather it will be in bloom in 30 days after it has been sown. This latter fact makes it especially valuable to put in after digging potatoes, or after other crops are taken off. It will also stand quite a little frost. On account of the above remarkable facts, it ought to be more extensively used by bee-keepers. This rape for the bees should not be confounded with the new Dwarf Essex rape. The latter is used for forage, especially

for sheep, and is usually fed or cut down before it comes into bloom.]

THE article by Mr. Langstroth, whose death is mentioned elsewhere, was written, as will be seen, some time ago; but, owing to the fact that not all the copy was received at the date, Aug. 13, and that proofs had to be sent and returned, its publication has been delayed until after the death of our lamented friend. Whether Mr. L. had already begun on his Reminiscences, so that there is some copy yet unpublished, I am not able now to state.

THE DRY-WEATHER WEED A GREAT YIELDER OF HONEY.

MR. J. C. WALLENMEYER, of Evansville, Ind., made us a short call a few days ago. He owns some 65 colonies in the region of the bayou of that place. He secures no honey from any source before the 1st of August, and that is from what is there known as "dry-weather weed." During dry seasons it yields bountifully a honey of good color and flavor; indeed, at its best it is estimated that there could not be colonies enough located in its vicinity to overstock the locality. In seasons when every thing does well by reason of rains, it does nothing, as was the case this year. By the way, Mr. Wallenmeyer has the distinction of being the composer of the sheet music entitled *Queenie Jaenette*, a waltz song. I dare not tell you out loud who "Jaenette" is; but let me whisper in your ear she is a real live person (I have seen her picture), known to Mr. W. There! I must not tell you more.

OWNING UP TO FAILURES; THE DARK AND BRIGHT SIDE OF BEE CULTURE.

SINCE the letter of J. P. Shaw in type, the following has come to hand:

Could not your pleasant tactics of showing up the good and praiseworthy be applied to Mr. Dosch's letter, page 737? Thousands all over the land say amen to what he says about the weather, etc.; and does it not take more courage and independence of character to own up to failure than to report success that is often only a streak of good luck? It is a consolation, too, for us unprosperous ones to know that there are more in the same boat with us.

Davenport, Ia.

A. GREER.

We do intend to give both sides a fair showing, especially the darker one; indeed, we do not publish by a long way all the favorable testimony we receive; and, on the other hand, we have tried to give space to *every thing* that is really discouraging, and which should be properly set before our readers. In evidence, see "Reports Discouraging" we have always

published at the proper season of the year. Years ago we used to have a department we used to call "Blasted Hopes." The trouble is, as you intimate, more with *bee-keepers* themselves who are too much chagrined to write than with the publishers. It is far easier to tell of our successes than our failures. But, say; is it not quite possible that friend Dosch made his picture overdark? See the favorable report in this issue by J. P. Shaw, on page 770, a man who lives only three miles from him.

QUEENS LAYING IN TWO STORIES.

I DID not notice that the article by Dr. Miller, on page 740, last issue, required a footnote until after the form had gone to press, so I shall now say what I should then have said.

When running for extracted honey I have had no trouble in getting the queen to occupy the second story, because, when she was crowded for room in the lower set, I simply took therefrom two or more frames and put them above, filling the space now made below with empty combs or frames of foundation. With the brood above, the queen, after filling the combs put in below, would go above. I have had as many as fourteen frames more or less filled with brood, and it was quite a common thing to have a dozen. When I had fourteen such frames I generally added a third story; and in this as well as in the combs of the second story not filled by the queen I got extracted honey—much more in proportion than from colonies having two stories and the queen confined wholly to the lower hive by perforated metal. What was more, those three-story hummers—for such they were for honey—never swarmed.

In running for comb honey the case is so different that I think I should try to confine the queen to the lower story; and whether, in the light of facts recently presented, I should want that brood-nest eight or ten, I can not say; though on account of the convenience of the eight-frame size I think I should prefer it. Taking it all in all I still prefer that size for both comb and extracted. For the latter it is large enough when tiered up; and in the case of the former it has and probably will give forth its tons of honey as before.

As to shallow brood-nests, all I can say of them is that I do and do not like them. From my present knowledge and experience I can not think that wide or deep top-bars are adapted to them. If, in order to use shallow brood-chambers, we must have narrow and thin top-bars with their attendant burr-combs—well, I *think* I should prefer to use something else, even if we were *sure* it were an advantage to use them.

DEATH OF REV. L. L. LANGSTROTH.

A COUPLE of numbers ago I announced that Mr. Langstroth's health had so far improved that he was in position to complete his series of

reminiscences, which had to be cut off owing to that distressing head trouble that has afflicted him for years; and only a few days before, a letter had come from Mr. L. stating that he was just about to begin on them. It was with much surprise and sorrow that we learned, on the 7th, that father Langstroth had died suddenly in the Wayne Ave. Presbyterian Church, about 11 o'clock on the 6th, while assisting the pastor, Rev. Amos O. Raber. The newspapers next morning contained quite extended accounts, and clippings from a couple of them were forwarded on to us at once; but knowing such accounts were not always quite reliable I wrote to Mrs. Cowan (Mr. Langstroth's daughter), saying that I hoped her heart would not be too full to give us further particulars. Below is her reply, giving the touching details of her father's death:

Mr. E. R. Root—*Dear friend*:—I can hardly tell you whether my heart is fuller to-day of sorrow for the loss of my dear father or of joy as I think of his blessed entrance into the land where "there shall be no more death, neither sorrow nor crying, neither shall there be any more pain, for the former things are passed away."

I can give you only a brief account of my father's last days. When asked, the Sabbath previous to his release, by our pastor whether he felt able to make the address at our communion service, he replied, "I shall be most happy to do so," adding, in response to the assurance that, if he did not feel able for it when the time came, he could be relieved, "Oh! I shall be able—it will be a joy to me, Mr. Raber. I am so glad you asked me!" He had been very bright and happy ever since his return from Toronto; but last week he took a heavy cold, and was much oppressed with it; and during the last few days he lost strength so rapidly, and seemed so feeble, that I wished him to notify our pastor not to depend upon his assistance on Sabbath. He was, however, confident that he could carry out his part in the services, and was so anxious to do so that I could not insist.

On Sabbath morning he was unusually bright, and overflowing with happiness and gratitude to the Lord for his blessings. My eldest son, with his wife and baby, had been spending a week with us, and he was much pleased with, and proud of, his little great-granddaughter. He asked her mother that morning to wheel her little carriage into his warm room, and I shall not soon forget how happy he looked as he sat beside it, talking to and caressing the little one. They were at the church.

After dressing, father seemed much fatigued, and I again asked him whether he thought it were best for him to try to preach. He replied, "Oh, yes! I will say a few words, and then I will come home and rest, rest, rest." He is most certainly "at rest with the Lord."

Before preaching, Rev. Amos O. Raber moved the pulpit to one side and placed a chair on the front of the platform. Father began to address the audience, sitting, with some explanatory remarks as to his weakness. After a few introductory sentences requesting the prayers of the congregation for himself and the service, he said: "I am a firm believer in prayer. It is of the love of God that I wish to speak to you this morning—what it has been, what it is, what it means to us, and what we ought—" As he finished the last word he hesitated; his form straightened out convulsively; his head fell backward, and in about three minutes he was "absent from the body, at home with the Lord."

There was no scene of confusion in the church. Tears were running down every cheek, but there were no screams, no loud sobbing. As one person remarked, "Heaven never seemed so near before; it seemed but a step."

"Then, with no fiery throbbing pain,

No slow gradations of decay,

Death broke at once the vital chain

And freed his soul the nearest way."

Sincerely yours,

Dayton, O., Oct. 8.

ANNA L. COWAN.

A. I. ROOT'S PERSONAL* RECOLLECTIONS OF THE
REV. L. L. LANGSTROTH.

In the Introduction to our A B C book you will find some mention of the incidents of my first acquaintance with the honey-bee. During the whole of my busy life, perhaps no other hobby has been pursued with the zeal and keen enjoyment that my acquaintance with the honey-bees has. It seemed for a time as if a new world were opening before me. After I had questioned again and again everybody who kept bees, or knew any thing about them in our neighborhood, I began impatiently ransacking books and periodicals. The more I found, the more I thirsted for deeper knowledge. I took a trip to Cleveland, principally to overhaul the bookstores for works on bees; but I did not dare to tell even the members of my own family that I was taking such a trip by stage-coach (for it was away back in the days of stage-coaches, before our railway was built), just to satisfy my thirst and curiosity in this direction. I remember well how the book-keeper pulled down his volumes one after another, rapped the dust off, and began extolling their special merits. It did not take me many minutes to decide that Langstroth's book was *the* book. I was obliged to stay over night at the hotel, for the stage made only one trip daily. I read and read, away into the night; and it was during that night I commenced my acquaintance with the Rev. L. L. Langstroth. He told me just what I wanted to know. My craze was not (certainly not at that time) to make money, but rather to know more about God's wonderful gifts—these strange and *curiously* wonderful gifts which he has provided for the children of men. I did not look at it then just as I do now; that is, I am sorry that, in those earlier days, I did not recognize the Almighty as a loving father. But Langstroth's book helped me a great deal, right in the line where I sorely needed help. His wonderfully genial, friendly, and sociable way of telling things enlisted my sympathies at once.

I told you I was not studying then for the *money* there was in it. Langstroth never wrote about bees or did any thing else because of the *money* there was in it. Through all his busy life, he, at least at times, seemed strangely oblivious of the *financial* part. More of this anon.

After I arrived home it did not take me long to find out whether Langstroth was still living. I made the acquaintance, by letter, of Samuel Wagner; got hold of Vol. I. of the *American Bee Journal*. By the way, I wonder whether there is anybody living now who will enjoy reading the first edition of Langstroth and the first volume of the *American Bee Journal* as I enjoyed it then. Why, the very thought of

* We hope to have personal recollections and historical incidents from a number of other writers, on Langstroth, in our issue for Dec. 1st or 15th. Announcements will be made later.—Ed.

those old days of enthusiasm makes the blood even now tingle to my fingers' ends.

As soon as I found that Mr. Langstroth was living at Oxford, Butler Co., O., I commenced correspondence. Then I wanted the best queen-bee to start with that the world afforded. It was pretty well along in the fall, but I could not wait till spring, as some of my friends advised me to do. I soon learned to look up to friend Langstroth with such confidence and respect that I greedily read again and again every word I could find from his pen—even his advertisements and circular in regard to Italian bees. When the book was read through once I read it again. Then I read certain chapters over and over; and when summer time came again, and I had little miniature hives or nuclei under almost every fruit-tree in our spacious dooryard, each little hive containing a daughter of that \$20 queen, then I read Langstroth's book with still more avidity and eagerness, finding new truths and suggestions in it each time.

I think I met him first and heard him talk at a convention in Cincinnati. He was a wonderful talker as well as writer—one of the most genial, good-natured, benevolent men the world has ever produced. He was a poet, a sage, a philosopher, and a humanitarian, all in one, and, best of all, a most devoted and humble follower of the Lord Jesus Christ. His fund of anecdotes and pleasant memories and incidents was beyond that of any other man I ever met; and his rare education and scholarly accomplishments but added to it all. No one I ever saw could tell a story as he would tell it. A vein of humor and good-natured pleasantry seemed to run through it all. I think he enjoyed telling stories—especially stories with good morals; and they all *had* to have a good moral or they could not come from L. L. Langstroth. Not only the play of his benevolent face and the twinkle of his eye, but the motion of his hands as he gave emphasis to the different points in his narration, showed how thoroughly he entered into his topic.

It was my good fortune to listen to him one or more times from the pulpit. He preached to us once here in Medina. The church was full, but I hardly believe any one else in that large audience enjoyed his talk as I did. They did not *know* him as I did.

You must not think from what I have said that our good friend always agreed with every one else. He had opinions of his own, and he could be stubborn and almost contrary when he got "hot" in a discussion. But the gentle spirit was back of it all. I remember once of being out in the apiary, explaining to him some wonderful improvement I had just been working out. He, however, did not see it as I did, and stoutly maintained that the old way—his way, in fact—was better. All at once I stopped

and concluded we had better give up the subject. Pretty soon he laid his hand on my arm, and said:

"Friend Root, will you not forgive me? I was rude and uncourteous. You have practiced this thing, and are succeeding. Very likely you are right and I am wrong."

Now, friends, how many times in this world of ours do you meet a man with a spirit like that? Once or twice I have knelt with him in prayer. Sometimes we have prayed together in regard to differences among bee-keepers; and I have always been struck with his remarkable gift in prayer. It seemed as though he were pleading with some dear friend, when he addressed his Maker.

His last public talk to bee-keepers, if I am correct, was the one given at Toronto; and I felt anxious at the time that some shorthand reporter might be at hand who could give all his words, and even his little stories, just as he gave them to us then. Perhaps others did not enjoy this talk as I did, because they did not know him as I did. Why, that history of long ago, telling of the troubles, blunders, and mistakes in introducing the Italian bees from Italy to America, should be handed down to coming generations. It should be embodied in some of the standard works on bees, in order to secure its preservation.

Langstroth and Quinby—those two old pioneers—have now both passed away, but "their works *do* live after them," and shall live for a thousand years or more. I feel anxious that the first edition of both Langstroth and Quinby should be preserved. There is something to me more interesting in their first efforts—Quinby's book, for instance, telling how to keep bees with a box hive, and Langstroth telling his first experiments with the movable-frame hive. Those early editions should be preserved; also the early volumes of the *American Bee Journal*, containing the writings of these two great benefactors of the world.

When quite a child I was greatly interested in reading the life of Benjamin Franklin. When I first became acquainted with Langstroth I could not resist the suggestion that he was much like Franklin. The maxims of Poor Richard suggest the thought. Mr. Langstroth was remarkably well read in ancient literature. He was familiar with the writings of great men in all the ages. It rejoices my heart now to know that he has been remembered for many years at our national conventions, and to know that he was even present with his daughter at the one that occurred so short a time before his death. He never seemed to have a faculty for accumulating property; but what is *millions* of money compared to the grateful remembrance with which Langstroth's name will be spoken in every civilized land on the face of the earth?

ON THE WHEEL.

My weight has finally been reduced to 110 lbs. To test the matter in regard to whether one loses strength by a corresponding loss of flesh, I decided to take a wheelride on the morning of Sept. 21—the hot Saturday you remember so much has been said about in the papers. After eating a whole pound of sirloin steak as a starter I rode 32 miles, perhaps easier than I ever did it before. There is certainly a big advantage in reduced weight for wheel-riding, although it may not be as true for different kinds of hard work. I now weigh from 20 to 25 lbs. less than my ordinary weight. Sometimes in doing errands it becomes necessary for me to carry some 10 or 20 lbs. on my wheel, and I find it makes a vast difference when I finish my errand and leave my burden. Now, is it not possible that thousands of people are carrying around with them day by day a useless amount of *avoids*? I do not refer especially to those people who are over-fat. My normal weight is from 130 to 135; and I confess I find it a great relief, especially on a hot day, to feel that I am 20 or 25 lbs. lighter, and yet no loss of strength and energy. By the way, is there any better way of reducing flesh than by the Salisbury treatment?

A few days later I started out to visit friend Gault. I wanted to see his raspberries during the last of September. The Weather Bureau said "fair weather;" but the barometer said "rain." I had my work all fixed, and I was in just the mood for a wheelride; so I started out in defiance of the barometer. I made eight or ten miles very easily, and with much enjoyment. Then it commenced to sprinkle; but as it did not sprinkle enough to make the dust stick to the rubber rims, and as I had on some very light thin clothing, I kept on in the rain. The rain was at first a sort of damp mist. But it kept getting wetter and wetter. Pretty soon I experienced the delicious sensation I have mentioned before, of breathing great breaths of water-laden air. I wonder if anybody else has enjoyed this while riding the wheel. It is much like drinking when you are thirsty, but you drink through the lungs. I enjoyed it so much that I kept on until I was pretty well wet through. Catch cold? Not a bit of it. When you weigh only 110 lbs., and your muscles are all solid lean meat, something like dried beef, perhaps, you can not very well catch cold. I kept on enjoying it more and more until finally the roads began to be too soft for wheeling. Then I was obliged to invade a little home by the wayside. I was permitted to help myself from a tea-kettle of hot water on the stove. Then I talked with the six-months-old baby, and got acquainted with the rest of the household, and put in an hour until the rain stopped, very pleasantly. By getting over to the nearest station I reached New London after 9 o'clock at night; but as the rain had spoiled the wheeling I got up at five o'clock and found the way over to our friend Dan White's just as the hired man was getting out of the back door. As soon as Mr. White was informed that A. I. Root was on the premises he hustled on his clothing quickly, making some apologies for getting up so late on a rainy morning. After we had shaken hands and talked over matters a little he commenced:

"O Mr. Root! You are just in time to see the

neatest thing in the way of a strawberry-patch there is out. Just come this way."

If our readers will now turn back to page 71, Jan. 15, they will find some diagrams in regard to setting out strawberry plants. Well, friend White's patch was a modification of this idea. In the first place, he marks out his ground in the spring of the year so as to put the rows 4 feet apart; then the plants are carefully set 18 inches apart in the row. As soon as they send out runners, one new plant is made to grow half way between the original plants. That leaves them 9 inches from center to center. Now the next step is to put a plant 9 inches off on each side of every plant in the row. The diagram below will make it plain. The large stars are the original plants, and the small ones where the runners are put down.

* * * * *

DAN WHITE'S SYSTEM OF GROWING STRAW-
BERRIES.

You will notice that the above arrangement makes the plants 9 inches apart from center to center; each old plant is to furnish three young ones. The row of plants is 18 inches wide, the path $2\frac{1}{2}$ feet wide. Well, after you get these three rows, plants 9 inches apart, then you are to pull off every runner. Go over the ground so often that not a weed gets a start, and not another plant gets a start except the three rows as given above. The effect is to make each plant, by the time frost comes, a strong bunchy cluster. It is several years since we first practiced taking off all the runners so as to get strong bushy plants; but I am firmly convinced that in no other way can we get such large fine berries.

The next question is, What variety shall we use? Dan White's model strawberry-patch is Gandys—nothing else. You know there has been a complaint that the Gandy does not bear very much. Some large strong plants, for instance, will not bear a single berry—at least, not the first season. Well, friend W. says it is because the plant has not grown to a sufficient size. He says if you take the first Gandy runners that set in June or July, give them good cultivation, and stop off all the other runners, you will get a plant by fall big enough to give a good crop of fruit next year, and I believe he is right. Our Gandys always did better the second season from planting.

This patch of strawberries on friend White's premises is, I believe, the handsomest, and the most of a model patch, of any thing I ever saw anywhere, unless it is those of Henry Young, Ada, O., that I looked at last winter. There are absolutely no weeds in it. There was a plant wherever there should be one, and no extra ones. And I tell you, friends, it is a grand thing to have a full stand in raising any crop. This reminds me that I forgot to say that T. B. Terry's potato-fields were absolutely a full stand. There were no missing hills—at least, I did not see any. But his planting was all done by hand. Since digging his Freemans he tells me that, on his best ground, they ran as high as 195 bushels per acre. Now, for the season we have had, especially the severe drouth in his locality, and for a potato of such *fine quality* as the Freeman, this is certainly doing pretty well, especially where a whole farm, as it were, is planted to potatoes. But, to come back to friend White's.

It is a big lot of work to set each runner in place by hand, and to pinch off all the superfluous runners. But, there is no excellence

without great labor. Friend W. had a large crop of strawberries during the past season, and sold them all at extra prices. Three or four cents more per quart for your berries will easily pay for the extra labor; and when you get right down to it, a good many times it is about as cheap to do any thing *right* as to let it go, or to get out the weeds by fits and starts after they have done a big lot of damage. He placed his berries right in the market, side by side with other berries that were selling at 5 and 6 cents. When the dealers protested about his asking 10 and 12 for his he replied:

"You need not buy them at all, my friend, unless you have a mind to. Set them right out here on the walk, put a tag on them, stating the price, and I will allow you a commission for selling."

If the above conversation took place on the sidewalk, where it usually does, about this time somebody going by wanted some of the berries. Then somebody else wanted some more; and pretty soon the dealer says, "Here, Mr. White, I will take them at your price." Now, this is the same thing Terry describes in his strawberry-book. It can be done every time when you have something away ahead of the general run in the market. Terry accomplished the matter of getting his plants so as to give each one plenty of room, by cutting out the surplus plants in the fall. Friend White's plan is more work, but I think it is a little ahead, because the surplus plants are out before they get started. And then, what a pleasure to show to your friends—I do not mean the berries—I mean the plants and the strawberry-garden! I should judge friend W. has something like a quarter of an acre close by his dwelling, managed on this high-pressure principle.

White breakfast was being prepared, a fine horse was quickly put in the buggy, and we went half a mile back through his raspberry-plantation. They are managed a good deal as he managed his strawberries—that is, the greater part of them—and they are certainly a sight to behold. The ground is nicely tiled, and it is just the kind of sandy loam that berries revel in. Sure enough, there were two rows of the Gault raspberries; but the demand for plants was so great the blossom-buds had all been picked off, and the tips were down in the ground. Yes, and his plants were all sold before they were fairly well rooted, even though he should have a couple of thousand. That is the way to do business, friends—make your product of such a grade that it is sold before it is ready to take out of the ground.

On the way back we passed a field of Stowell's Evergreen sweet corn that so took my fancy I engaged then and there ten bushels of shelled corn for seed.

"Breakfast is ready!" As friend White's oldest boy, Ford White, is under training for bicycle-riding—that is, a sort of home training—he kindly shared his nice beefsteak with me, so I came out all right, even if I was driven off my route by the rain. Then friend W. and I were off for friend Gault's plantation, seven miles away. But, lo and behold! just as we were crossing the railway, our genial friend Gault was seen coming for us with great strides. He was on his way to the Elyria fair, with a basket of Gault raspberries to be exhibited; and so I did not reach his plantation at all that day, but made him turn round and go to the fair, even though he protested somewhat.

Two things at Elyria attracted my attention especially. One was the great show of potatoes, including almost every variety of any note. In fact, there were potatoes enough to fill the vegetable department to the exclusion of all

else, and they had to fix a sort of "annex" for them outdoors. The other thing that attracted my attention—well, it did not just exactly attract *my* attention, after all, so much as it seemed to call the attention of the crowd in general. It was not the big potatoes nor the big squashes, nor friend Gault's show of raspberries toward the first of October; but it was a great lot of establishments for games of skill and chance—throwing a ball at a doll-baby, with a cigar for a prize; shooting at the mark, and other things that ran so near gambling the sight was any thing but inspiring to me. Why should the gambling-mania and rural industries be thus linked together hand in hand, as it were, at our county fairs? By the way, I wonder if there is any sort of *diet*, or any sort of wholesome food and drink, that we could furnish to our boys and girls to discourage this disposition toward the *gambling-mania*. No doubt these fellows make money, or they would not work so hard to call people to their respective places. They evidently get a pretty big harvest of nickels or they could not afford to pay the fair-managers so big a sum for the small amount of space they occupy. By the way, where do our farmers' boys and girls get so many nickels, anyhow, for popcorn, candy, games of chance, etc., if it is true that "farming doesn't pay"?

On a later day, when it did not rain, my wheel and I managed to reach friend Gault's; but it was only after there had been frost enough to "cook" (at least partially) the Gault raspberries. But a small part of friend Gault's plantation is allowed to bear fruit, because the demand for plants is so great. We found stacks of great clusters of berries, picked and brought into the house before the freeze, some only half ripe, and a good many more on the bushes, that had been covered with old sacks, blankets, etc. Surely, no other raspberry ever bore its fruit in such tremendous great heavy clusters and bunches. I think one single shoot contained, by actual count, 248 berries; and there was any quantity of them having from 50 to 100. On the old plantation there were single branches lying flat on the ground. In fact, the Gault raspberry is almost sure to lie flat on the ground, through its weight of fruit, unless it is tied up or supported in some way. Although we have some very large fine bunches on our grounds, our plants have not as yet shown as much disposition to fruit heavily as they do on the grounds of the originator. Of course, the frost last spring made havoc with the fruit in every locality. When it comes to raising fruit for the market, these great bunches must be supported in some way, or tied up, or they will be in a worse plight from the effects of mud and sand than even strawberries.

It is really worth while to see friend Gault exhibit his berries at a county fair, and notice the animation with which he answers questions, and explains to everybody his new raspberry. I presume he could take a large number of orders for plants, to be sent out this fall; and I fear that nurserymen *generally* will not be as conscientious as he is in advising everybody to wait until spring, and not undertake fall planting with the Gault raspberry.

FLORIDA TRAVELS.

Just here it occurs to me that several items in regard to our Florida trip were not taken in their proper order. This is not very strange, as it is now several months since I made that pleasant trip. In writing up Silver Spring in our last issue I omitted to say that it was my good fortune to be present when the steamers both came in with their merry crowd of laugh-

A FLORIDA ORANGE-GROVE IN FULL-BEARING, SHOWING HOW THE PROPRIETOR LOOKS WHEN HE IS HARVESTING A BIG CROP, AND PRICES ARE GOOD.

ing passengers. After the water had become quieted, and as the boats stood there for some little time, I went out on one of them and looked over its edge into the water, straight down where the pool is perhaps deepest. The water is so clear it really made one dizzy—straight down 85 feet into a liquid that is brighter and clearer, or at least it seemed to me so, than even the air itself. It made one feel strangely. When two steamers start out there is generally a little rivalry to see which will get away first and get into the narrow channel higher up. Upon the arrival of the steamers the alligators perched along the banks and by the roots of trees (like a lot of frogs and snapping-turtles) make a sudden plunge into the bright water. It was my good fortune to see four good-sized ones popping their heads up after the water had stilled down a little. Getting a glimpse of the 'gators, especially the large ones, before they are disturbed and tumble in, is one of the exciting sights for passengers down the Ocklawaha River.

In the vicinity of Silver Spring there are many sink-holes or cavities in the earth, such as I mentioned in Missouri. And, by the way, are not these found more or less in all localities where great springs and artesian wells are prevalent? On my way back to Ocala, the stage-driver told me there was a spot a few miles out of town where a horse broke through on the level ground. His rider managed to grasp the crust of earth and thus saved himself before the horse went down clear out of sight. As he was a valuable one, however, the neighbors rallied; and as they could hear his breathing from the depths below they set to work and dug him out—or, at least, made a sloping path so that, by the assistance of ropes, they enabled him to climb out himself.

On my trip back from Ocala to Palatka my curiosity was greatly stirred up by the kaolin-factories. This kaolin is manufactured from a species of clay found in different parts of Florida. It is used in the manufacture of fine china and earthen ware. The factories are quite extensive, and the process is, I judge, somewhat complicated. They seem to employ a good many men, and are doing a large business. I wish some of the Florida friends would write up briefly this matter of kaolin.

At Palatka there was a great crowd at the station, as several trains leave about the same time in the afternoon and evening. Of course, they have railroad officials appointed to answer questions and tell people where to go. But these men are asked so many questions and (oftentimes so many foolish ones, perhaps), that they sometimes get crusty and uncivil. You know how it is, friends. They will answer your question in as few words as possible, and look the other way while talking. Well, I was greatly pleased to see a pleasant-looking middle-aged colored woman on the platform, and she was kept very busy indeed, showing people what train to take, taking them by the hand, if need be, and pulling them through the crowd to show them in that union depot where to get a ticket, what train to get on, etc. I had already an excursion ticket, but it obliged me to go around by St. Augustine, which would delay me another day in getting to Jacksonville. This woman helped me to get on the right train just starting out, that would reach Jacksonville that night; and the additional expense was little if any more than my board and lodging would be if I had waited till another day. Now, some of you may make fun of me, perhaps, when I say that colored people have a remarkable fund of patience in answering cheerfully and good-naturedly all the questions

you may put to them. This woman was smart and bright, and evidently knew all about the railroad machinery of travel as well as any of the men. I do not know who pays her for her time; but very likely it is the railroad companies. But with such a stream of humanity, many of them tired women with children, perhaps crying babies, this bright cheerful woman was surely a ministering angel, even if she was black.

In reaching Green Cove Springs, mentioned in my last, I took the steamer from Jacksonville. Well, somewhere in the vicinity of Magnolia Springs I saw cows wading away out into the St. Johns River, and actually eating grass or something else, with their heads entirely under water. At first I thought them some strange sea-monster. I did not know but it was the genuine manatee, or sea-cow, found in the Indian River, away down in the vicinity of Potsdam, where friend Poppleton lives. Somebody has since told me that I must be mistaken, for a cow can not live with her head under water. But I tell you she can live and does live with her head entirely under water, and out of sight, for a good many minutes. I think I saw half a dozen or more with not a head of one of them in sight, and their huge bodies were more than half under water at that. They had evidently learned the trade by long practice. I do not know what sort of forage it is that grows at the bottom of the St. Johns River; but I think it would be a splendid thing to cultivate, especially during *dry seasons*. Will somebody who lives down that way tell me more about it? I also omitted to say that that wonderful Green Cove Spring sends out 5000 gallons of shining water every minute.

When I was down at Mt. Dora lamenting that I could not see those great orange-trees in full leaf, somebody—it may have been my good friend Nellie Adams—said:

"Oh! yes, you can, Mr. Root. Here is a picture that will show you just how they look."

The man in the foreground may have been her brother; but it is really so long ago I can not remember, and I neglected to mark it on the back of the photograph. Whoever the person is, I am afraid his smiling face got a damper after the terrible frosts of last winter. Maybe he has by this time got so as to look good-natured and happy again. I hope so. Some people have but little idea of the immense size to which orange-trees grow in a favored locality.

OUR HOMES.

Create in me a clean heart, and renew a right spirit within me.—PSALM 51:10.

I have before alluded to the fact—a wonderful fact it is to me—that, by a certain course of diet, one is free from the cravings for intoxicants and stimulants, or even a craving for what are called "temperance drinks." I still enjoy the hot water, and still prefer it to any other beverage the world can furnish. In fact, I am now using hot water at my meals, instead of the tea the doctor permitted me to have. I do not need the tea, and I do not want it. The water is nicer. Of course, with the large quantity of water drank in the middle of the forenoon and middle of the afternoon, very little liquid is wanted at mealtimes, and that is all the better.

Now I hope our readers will pardon me for touching upon another point—a point that is seldom talked about in print, but one that has very much to do, not only with the morals of

our people at large, but still further in regard to the matter of suppressing crime. We have been told by eminent physicians and clergymen that sexual vices may be productive of more evil in this world of ours than even a taste for intoxicants. The older readers of GLEANINGS will remember that I have at different times alluded to my own temptations in this line, especially during my early life. I have prayed long and earnestly over the matter since I became a Christian, and have many times wondered if it were not my "thorn in the flesh" that God thought best not to remove, but to give me grace to bear. Through correspondence and through personal intercourse in my travels and during my wheelrids, I have found many another good brother who has confessed to me his trials along this very line. It is, without question, one of Satan's greatest weapons; and it is a work that he carries on, not only among the lower classes, but it comes clear up through all grades of society. We have but to glance over the newspapers and notice the startling accounts of crime, often revealing the fall of those who stood in high places. Well, there is a remedy. One who secures perfect and complete digestion not only finds himself free from unnatural cravings in the line of beverages, but this strange, restless, uneasy feeling that comes of itself, many times so unexpectedly—these phantoms of the imagination that we all ought to be ashamed of, and many of us are ashamed of every day of our lives—these, too, give way and disappear when the blood flows evenly through the veins, without being disturbed or wrought up by a disordered digestion and consequent unnatural cravings.

It would seem as if a great part of the crime abroad in the world were the result, not alone of a bad state of the heart, but as a consequence of the bad state of the *stomach* and *intestines*. Over-eating has for ages been recognized as a promulgator of unnatural longings and consequent crime. Now, it is not only over-eating and over-drinking, but I am satisfied it is the wrong *kind* of eating and wrong kind of drinking that pave the way for Satan's work.

Some little time ago I quoted to you a part of a talk from Anthony Comstock in regard to "evil imaginations;" and I have wondered why God permitted good men—devout, Christian men—to be haunted with imaginations that evidently must come from the evil one himself; yea, verily it seems at times as if they must come from the bottomless pit. I have prayed over the matter, and answer seems to have come with the prayer. For many weeks I have been entirely free from any thing of the sort. Pardon me if I be frank enough to tell you that, for the first time in almost *fifty years*. I have enjoyed perfect freedom and immunity from suggestions of the imagination that I should be ashamed to have my wife, mother, or grown-up daughters know all about; that is, if they could read my very thoughts for the past few weeks there would be nothing in that line to be ashamed of or to fear to have them see. Now, from my acquaintance with mankind I know that this is, at least as a rule, something remarkable. In a recent issue I suggested that wholesome digestion might be more than the Keeley cure has ever *claimed* to be, in the way of preventing intemperance. It would stop the mischief at the fountain-head. I ought to say more—that perfect natural digestion, such as God intended we should have—would stop at the fountain-head this other twin evil, or twin demon, of the evil one. It would be a most perfect cure for licentiousness. No, you need not be afraid that there would not be *people*

enough born into the world. We might have a less number, but we should have a better sort of people. What there would be lacking in *quantity* would be made up in *quality*. There is many a man so honest in dollars and cents that he is never tempted to touch, or even *covet* the gold that belongs to his neighbor and not to himself. So far as money or property is concerned, he could live up to the golden rule; but when it comes to that part of the tenth commandment where he is commanded not to covet his neighbor's wife nor maid-servant, it may be a different thing with that person. When a man can look upon all womankind as he would upon the daughters of his own household, then he may be said to be truly born again. He is a child of the new birth; and I am firmly convinced that so simple and prosy a matter as the choice of his food and drink may prove to be a great factor in perfect emancipation from this form of evil. This thing *alone* may lift him from the "house of bondage."

There seems to be an impression very widespread, that the use of meat as a diet tends to develop the animal passions. This may possibly be true when taken with large quantities of vegetable food, sweets, etc. But it certainly is not true on an exclusively lean-meat diet. It can not be that meat conduces to the accumulation of flesh or fat, for the Salisbury patients invariably lose flesh for at least quite a time, say perhaps for several months. And, by the way, it seems that, where it is desirable to reduce one's weight, there can be no safer or simpler remedy than the lean-meat diet. If it is not meat, then, that makes people fat and heavy, and develops the coarse animal nature, to what part of our food should we attribute this result? After having given the matter considerable thought, my impression is that the excessive use of sugar or other sweets has much to do with it. On page 711 I quoted from Prof. Atwater in one of the United States Agricultural Reports. Let me quote again, for I think a part of one of the quotations will *bear* repeating:

We consume relatively too much of the fuel ingredients of food—those which are burned in the body and yield heat and muscular power. Such are the fats of meat and butter, the starch which makes up the larger part of the nutritive material of flour, potatoes, and sugar, of which such enormous quantities are eaten in the United States.

Please notice the concluding sentence. Statistics have told us again and again that the consumption of sugar, especially the amount per individual, is constantly on the increase. The low price of sugar has probably had much to do with it, and a fondness for sweet things. It is not only at meal-times; but our ice-cream soda-fountains, our temperance or summer drinks, are largely composed of syrups, and everybody seems to want them as sweet as possible. On the fairgrounds during this season of the year, great quantities of sugar are used in making different kinds of cream candy. I have many times wondered why people would shower down their nickels for a little piece of hot melted sugar, when a moment's reflection should tell them that the nickel would buy ever so much more pure sugar right at any corner grocery. There is plenty of sugar in the sugar-bowls at home, to be used at meal-times; yet all through the day our children are spoiling their teeth, spoiling their digestion, and may be spoiling their moral and spiritual natures, by this excessive use of sweets. Prof. Atwater may well say, "In such enormous quantities." Of course, sugar has its use as an article of food; but after being without a particle of it for many weeks, I experienced no particular inconvenience. On tasting a little a few days ago, by experiment,

I was surprised to find that I had to a considerable extent lost my taste for it; and I must think it is a good deal an acquired taste. If I am correct, starch and sugar are at the bottom of half the dyspepsia and indigestion that afflict our American people. In fact, the Salisbury treatment is largely based on feeding the patient on something that contains not a particle of either starch or sugar. This is not a new idea by any means. In diabetes, and perhaps other diseases, the patient is obliged to guard against articles of food containing starch and sugar as he would guard against poison. Our good friend Dr. Jesse Oren, at Daytona, Fla., told me that for many years he had been obliged to practice this sort of diet. He has a sort of bread or cracker called gluten cracker, I think, which contains no starch, and, of course, he subsists largely on lean meat, as I do. Now, when it becomes apparent, or seems to become apparent, that it is not only a damage to our physical natures, but a damage to our moral and spiritual natures as well, does it not behoove us to look after these things?

Many times we hear people speak about avoiding meat for supper, or just before they go to bed. For years past I have been obliged to be careful about eating fruit, pies, or cake very near my bedtime. But for more than 25 years I have been aware that I could eat lean meat for a late supper just before going to bed, without having my rest at night disturbed a particle. Now, then, friends, when we use that oft-repeated prayer, "Create in me a clean heart, O God, and renew a right spirit within me"—and I hope the thousands of our readers have been using that prayer for years past as I have used it—when we take these sacred words on our lips, does it not behoove us to be careful of our diet? In our recent Bible readings in the Old Testament I have been struck again and again with the fact that the patriarchs in olden times, in an age when men lived to be from 500 to 1000 years old, nearly all had their large flocks and herds; and their sheep and oxen were counted by the hundreds and thousands; and on fast-days it would seem, indeed, from the accounts of the number of animals used for a feast, that they must have been largely a meat-eating people. We do not read much about sugar and candy in those olden times. In fact, milk and honey seem to have been the nearest approach to it; and if we were using milk and honey now (instead of sugar at 4 or 5 cents a pound), with meat in the quantities evidently consumed away back in the childhood of humanity, who knows but that we might live and hold our strength and vigor for a hundred years or more?

For years past, Mrs. Root has constantly urged me, especially when my health was poor, to eat more lean meat and less of other things. But some way, after indulging in sweets and fruits I would get a dislike for meat, and oftentimes give it up altogether until I was obliged to call a halt. Dear reader, if you are afflicted with poor health along the lines I have indicated, just try for a little time using more lean meat and less of sugar and starch, and see if I am not right. You may urge the matter of expense; but the dearest "feed" that anybody can find is that given by doctors, and bought at the drugstore. And, by the way, poor people, and those in moderate circumstances, a great many times employ the doctor a great deal more than the rich. Is this not true? People who are too poor to pay a doctor, and, in fact, never do pay him, oftentimes are the ones who are wanting the doctor continually.

Right here it would seem quite fitting that I should give some extracts from a letter just re-

ceived from my old friend and physician, Dr. J. H. Salisbury, the originator and discoverer, if I am correct, of the system of treating disease, that has received his name, not only throughout England and America, but almost if not quite throughout the whole world.

Dear Mr. Root:—You must be rigid, and follow out the instructions accurately, and put your whole soul and body into the work, if you desire to make good progress. Keep the bowels well open, stomach well washed out, and urine clear, and be careful not to overeat. Rest before and after each meal 15 minutes or half an hour if possible, and be careful not to overdo on the bicycle. You will enjoy life as never before if you will simply live rightly.

Yours very truly,

J. H. SALISBURY.

170 W. 59th St., New York, Sept. 27.

P. S.—When bowels do not move by 9 or 9:30 A.M., then take one injection of 1 pint of warm water, with two tablespoonfuls of glycerine in it.

J. H. S.

In addition to the above he makes some comments on my own instructions in our issue for Sept. 1:

Use Enterprise meat grinder No. 10, and put beef through from three to five times, according to quality of beef. Butter is not allowed in bad cases.

IN REGARD TO THE HOT WATER.

Take water at a temperature most comfortable to the individual, but not cold.

Several years ago a farmer of my acquaintance showed me a small, insignificant-looking potato. He said he had just got it as a premium for subscribing to the *Rural New-Yorker*, and that it was the "Rural New-Yorker No. 2." A year or two later a good deal was said about this potato; but people generally seemed to be a little slow in recognizing its good qualities, and it was not until three or four years ago that I gave it a trial on our own grounds. You may remember I reported at once that it gave us the only nice good-sized potatoes, free from scab, we had that year, the season being quite unfavorable. Since then it has seemed to be steadily growing in favor. Last fall, in my absence, Ernest bought a load of potatoes, paying, as I thought, a pretty good price for them. He urged that they were worth it on account of the large size and smooth round appearance, and finally had a load of them put in his own cellar. I told him they were a nice-looking potato, but that they were not extra for table use. To my surprise he declared they were the best potatoes they ever got hold of. This, perhaps, may have been later on, toward the spring. Well, the *Rurals* are now one of the standard potatoes in our locality. Farmers who never succeeded in getting any nice potatoes before, have, with the *Rurals*, secured large yields of fine clean potatoes. The son-in-law of the old farmer who first showed me that little potato, years ago, has this season about 800 bushels from four acres of ground. Our good friend Merton G. Chase, who raises such nice crops of honey every year, no matter whether the season is good or bad, secured 75 bushels of the *Rural New-Yorker* potatoes from a quarter of an acre of ground; and they are the handsomest lot of potatoes, for a large potato, I ever saw in my life. Just think of it—300 bushels to the acre! I told him I thought he must be a high-pressure farmer as well as a

high-pressure bee-keeper. I bought all he had to spare, and the Rural New-Yorkers we have for sale include this lot. From the reports in the agricultural papers, I judge this potato has been a great boon to mankind the world over. It would be hard to estimate the good that the *Rural New-Yorker* periodical has done the world in so steadily disseminating this one potato. Perhaps it has not quite done the work that the Concord grape did for years along in the same line. And, by the way, I have just been pained to note the recent death of our friend Bull, who originated and gave to the world the Concord grape. It had been in my mind to do something toward the contribution that the *Rural New-Yorker* has been taking up for him; but I put it off, and now he is gone.

The new Craig potato resembles the Rural perhaps more than any other. The potatoes are still larger—at least, they seem so this season, and I imagine the quality is a little better. The vines, instead of standing upright, however, like the Rural, lie down and run all over the ground. In fact, the general average, when stretched up full length, are now about as high as my head. But the frost last night, Oct. 9, has wound up growth for the season. There has been some objection made to a potato that never ripens up until frost kills it. I hardly think it will hold good in this case, however. Please let us hear from you, friends, when you dig your Craigs. A postal-card report will be sufficient.

The Early Ohio and Lee's Favorite, planted the last day of June, where we picked our strawberries, gave us a good yield of nice potatoes; and the Whittaker onions, mentioned in our last issue, were put in the same afternoon the potatoes were dug; so now we have the third crop growing on the same ground during one season; and the ground was plowed up after each crop was harvested, instead of the interlapping crops by planting between the rows.

A REPORT FROM THE CRAIG POTATOES.

MR. ROOT.—I have dug part, and shall have 160 or 175 bushels of Craig seedling potatoes. I planted about 2½ bushels. The potatoes were cut to one eye, and planted one piece in a hill, 3-foot check rows, ordinary cultivation, and no manure or fertilizer. There was a little over ½ acre, but many hills did not come up—I think probably because the seed was hastily cut, and extremely dry weather at planting. They were grown on a heavy sandy loam that had grown two crops of Gandy strawberries and one of millet since manuring. I had very few small potatoes; season was very late.

Leslie, Mich., Oct. 10.

C. N. FLANSBURGH.

Now, 175 bushels, grown from 2½ bushels of seed, will be equivalent to about 70 bushels from one planted. Why, that is even better than my first experiment of last season. I planted one potato, that weighed perhaps one pound, that gave me a bushel—60 lbs. from 1 lb.; but friend F., in the report above, has made a whole field, where he planted 2½ bushels, do as well, and over 300 bushels per acre!

Special Notices.

A GOOD CHEAP PUMP.

We call the special attention of our readers to the Leader pump we offer in another column. There are few people, especially in the country and small towns, who do not use a pump. We believe you will find in this a rare bargain. It may be used for a windmill pump, but the connection for that use costs 75c additional.

CHICAGO BRANCH.

As we go to press we are loading a car of assorted stock for our Chicago branch at 56 Fifth Ave., where our manager, Geo. W. York, will be prepared within a week or ten days to supply all who find it more convenient to trade in Chicago. We will aim to keep there a pretty full stock, especially of the goods most commonly called for. Occasionally or-

ders may have to be forwarded here to be filled if odd-sized goods or something unusual is called for.

SQUARE CANS FROM CHICAGO.

We have made arrangements with a manufacturer of cans in Chicago, to fill orders for one and five gallon square cans so that we are now prepared to ship either from New Orleans, St. Louis, Chicago, Conneaut, Ohio, or from here, at \$6.50 for 10 boxes of two 5 gallon cans with 1½-inch screws; \$15.00 for 25 boxes. Orders for cans from Chicago may be sent here or to our Chicago branch. As the 1½-inch screw seems to be the standard, we have gone back to that size instead of the 1¾ as advertised in our catalog. Special low prices quoted on large lots or carloads.

FACTORY BUSY, AND RUNNING FULL TIME.

What with orders for potato-boxes and other outside work which we have taken in addition to the good demand for supplies from some sections because of a fair crop of fall honey, we have been kept very busy in our wood-working department, and have sometimes been a few days behind on orders for bushel boxes. We are now up on our orders, and are laying up stock preparatory to next season's trade. We shall be glad to hear from those who are in the habit of supplying their needs for the following season in the fall and winter, and any others in search of special prices for buying out of season. Let us have a list of your requirements. The more goods we can place during the fall and winter the better, as it helps distribute the work through the year.

ADVANCE IN PRICE OF GLASS.

There have recently been several sharp advances in the price of window glass. Indeed, present prices are about double what they were last spring. There is a good prospect that these prices will not only be maintained, but will even go higher. We have laid in a good stock of shipping-case glass at very nearly the old price, so we are not obliged yet to mark up our prices to an extent equal to the general advance in the market. Until further notice the price of strips listed in our catalog will be as follows: On all other sizes cut to order, \$3.00 per box of 50 feet.

	Price of
	10 100
3x17½ for 24-lb. single-tier cases, - - -	30c \$2.40
3x13½ for 3 row cases, - - - - -	25c 2.00
2x9 for 2 row cases, 12 lb. - - - - -	10c .80

The price of shipping-cases complete with glass will be advanced to correspond with above advances.

HIGHER PRICES ON WIRE NETTING EXPECTED IN THE NEAR FUTURE.

We have no assurance that the exceedingly low prices on wire-netting, given on third cover page of this number, will last more than two or three weeks longer. Indeed, in view of the advance in price of iron and steel made during the past few months, the present low prices can not be maintained. The manufacturers will undoubtedly arrange for higher prices the first of next month. In view of the prospect of higher prices we have laid in a stock of 200 rolls in addition to our present stock of over 100 rolls; and until further notice we will accept orders at the prices quoted in our advt on 3-inch No. 18, 2-inch No. 20, and 2-inch No. 19, the three sizes we keep in stock here. Orders for other sizes received during the next two weeks we can doubtless fill at these prices, but we can not guarantee them for a longer time; and even during that time they will be taken subject to acceptance of the manufacturers. We look for an advance of 20 to 25 per cent. It is a good time, therefore, to anticipate your needs and buy at present low prices. We have been doing this in several lines which are advancing; and, to get back the money we have been thus investing, we invite orders at the present low prices. If you anticipate using netting next season it is our judgment that you will make a mistake if you do not buy now while present low prices may be had.

ADVANCE IN WIRE NAILS.

Of the advance in prices during the past few months there have been none so radical as that of wire nails. While nails were selling last April at a base price of 85c a keg for 60d, the bottom now for the same size is \$2.85—an advance in 6 months of \$2.00 a keg, and there is talk of still further ad-

vances. While we had a fairly good stock when the advancing market set in, we were not as well provided for as we now wish we were. As we have now to buy at the higher price, we are obliged to advance our catalog prices, and append a new table of prices which go into effect from this date till further notice. Since we have adopted the practice of including nails with every thing we ship where needed, we have used a good many more nails, but have not been selling separately nearly so many as formerly. This great advance in nails, of course, increases the cost to us of all articles we ship with which nails are included; but we do not propose making any advances in the price of these articles to compensate for this increased cost.

PRICE LIST OF FINE FLAT-HEAD WIRE NAILS.

Cement-coated, except first four.

L'gth.	Wire Gauge.	No. in 1 lb.	Wt. of 5c Pkg.	No. in 1 lb.	Price of 10 lbs.	100 lbs.

SEED POTATOES FOR FALL SHIPMENT.

During the past few days there has been considerable uncertainty and quite a little anxiety among potato-growers in regard to prices. In fact, for a time it was feared, and perhaps with some cause, that our high-pressure gardeners who had been so lucky as to get 300 bushels per acre were not going to be able to dispose of them at any price. Just now buyers have appeared, however, and potatoes are moving off rapidly here and there to supply destitute localities, or localities where they are not so plentiful. While they were low we bought quite heavily; and until this stock is exhausted we are going to make you some offers below any thing we ever saw before in print.

First, we will furnish good nice large State of Maine potatoes for only 25 cts. per bushel; but at this very low figure, however, you must pay for the package. It may be a five-cent bag, or it may be a ten-cent slatted potato-box; or if you want a barrel or more, and prefer to have them shipped in barrels, the price will be 25 cts. for the barrel containing 11 pecks. Now, please do not imagine that the State of Maine is not as good as some others because it is offered so low. I believe it is generally recognized as one of the standard first-class potatoes of the present time. On our own table they are dry and mealy, and equal to any, unless it is the Freeman and New Queen.

For 35 cts. per bushel we can furnish you the well-known Beauty of Hebron, nice large smooth potatoes, good size, and free from scab. For 40 cts. per bushel we will furnish Rural New-Yorker No. 2 or Monroe Seedling. The latter are those raised by Wilbur Fenn, Tallmadge, Ohio—the late-planted I have described. These are in many respects like the second crop of potatoes for seed so much advertised in the papers. Our customers who have pur-

chased friend Fenn's potatoes heretofore will know what they are like.

Charges for the package to ship in, the same as above. The above varieties, at the low prices we offer them, are all medium size. We have no second sizes. Prices of other varieties will be as follows:

Early Ohio, Early Puritan, Lee's Favorite, will be: Peck, 20 cts.; bushel, 60 cts.; 2-bushel bag, \$1.00; barrel, of 11 pecks, \$1.50, package included.

The prices of New Queen, Freemans, Burpee's Extra Early, Livingston's Banner State, 1 lb. by mail, postpaid, 15 cts.; 3 lbs. 35 cts.; peck, by freight or express, 35 cts.; bushel, \$1.00; two-bushel bag, \$1.75; barrel of 11 pecks, \$2.50.

All of the above, except the four varieties first mentioned, will be furnished at half price for second size—that is, when we have second size in stock. Of course, this half price does not refer to potatoes by mail, because the principal expense for these is the postage. Those who want extra-large potatoes can have them by paying a half more; and this year we have extra large ones of almost all the varieties, and I tell you they are beauties.

Since the frost, to fill occasional orders we have commenced digging our Craig potatoes. The yield is going to be very large, and the potatoes are going to be very large. After digging 30 or 40 hills we found one weighing 2 1/2 lbs. Many others came pretty near that figure. In fact, the potatoes in about one bushel in every five as we dig them will weigh over a pound apiece. These we are going to put by themselves as "extra large." All below that will be "medium" until we get down to about one ounce; all below one ounce will be called "second size;" and a few, say from the size of a hickory-nut down to that of a bean, will be called "third size." Extra large will be a half more than the list prices. Second size will be a half less than list prices. The third size will be 1/4 of list prices. As the Craig potato seems to run naturally rather too large, if any thing, for table use, we need not be so much afraid to plant the second and third sizes. Another thing, in order to discourage so many large potatoes it will be really better to plant them pretty close together—say have the rows only 30 or 32 inches apart; cut to one eye, and plant the eyes in the furrow, not more than a foot apart. In this way the yield will be enormous, and the potatoes will be full size. Although the ground on which we have planted them was cropped to potatoes last year, and in spite of the fact also, that we have been much troubled with scabby potatoes on our heavily manured ground, the new Craigs are almost entirely free from scab.

Our whole stock of the New Queen and Freeman was raised by T. B. Terry—medium, extra-large, and second size—and they are about as fine a lot of potatoes as I ever saw. T. B. Terry's second-size Freeman potatoes have always been sold out long before spring; therefore if you want them you had better put in your orders early.

We can furnish new Craigs, medium size, second size, or extra large; in fact, the biggest part of them run extra large. Prices as follows: Single pound, by mail, postpaid, 20 cts.; 3 lbs., 50 cts.; 1/2 peck, by freight, 50 cts.; peck, 90 cts.; 1/2 bushel, \$1.50; 1 bushel, \$2.50; two-bushel bag, \$4.50; 1 barrel of 11 pecks, \$6.00. Package is included with all of the Craigs. If you want to see the potatoes and try their cooking qualities before purchasing, we would advise you to order a pound or so by mail, to test them.

All of the above prices are subject to an advance by our next issue. If you wish to avail yourself of these exceedingly low offers, you must make your order at once as soon as you receive this.

Here is what T. B. Terry says about the New Queen and Freeman.

FRIEND ROOT:—The New Queen! a safe standard early potato for the masses. I have advised hundreds of people by letter to get them, during the last five years, and have never heard a word of complaint. I am afraid to advise every one to get the Freeman, as they require a better culture. To those who are still growing the old Early Rose or Hebron, or some mixture of them, or some other old early potato, the Queen will be of considerable value. My seed raised in Maine cost me over \$5 per barrel there; and is strictly pure, with the benefit of the change from Maine. We are eating them every day; and a whiter, nicer potato, with as much starch in, I do not know of, except the Freeman. I myself can make the Freeman outyield them; but with mine out of ten it would probably be the other way. I will send you some to eat, so you can see and particularly taste, for yourself. All letters for the Freeman will be sent to you from now on; and all orders or inquiries for some good early potato will also be sent you. I must get rid of the worry of answering letters and filling orders if possible. Beautiful rains now. How I wish my potatoes were still growing!

Hudson, O., Aug. 30, 1895.

T. B. TERRY.

HATCH CHICKENS BY STEAM—
 With the **MODEL**
Excelsior Incubator.
Simple, Perfect, Self-Regulating. Thousands in successful operation. Guaranteed to hatch a larger percentage of fertile eggs at less cost than any other hatcher. Lowest priced first-class hatcher made. **GEO. H. STAHL,**

Advantages of Bee-Escapes.

No sweat steals down the heated cheeks and aching back of the bee-keeper as the result of standing in the hot sun puffing, blowing, smoking, and brushing bees; no time is wasted in these disagreeable operations; and no stings received in resentment of such treatment; the honey is secured free from black or even the taint of smoke; the cappings are not injured by the gnawings of bees; and robbers stand no show whatever. If there are any broken burr-combs they are cleaned up by the bees inside the hive, before the honey is removed. **Leading Bee-keepers use the Porter Escape**, and say that without a trial it is impossible to realize the amount of vexatious, annoying, disagreeable work that it saves. The cost is only 20 cts. each, or \$2.25 per doz. As in the past, this escape is manufactured by the Porters, but The A. I. Root Co. has secured control of the sale for this country. Order of your dealer or of

THE A. I. ROOT CO., Medina, Ohio.

RURAL NEW-YORKER and Early Ohio potatoes, extra fine at 70c per bushel, barrels included.
EDW. SMITH, Carpenter, Madison Co., Ill.

Our Leader Pump,

For Wells and Cisterns.

We have frequently had calls for a good well-pump but have not heretofore tried to supply the demand. Having a very favorable opportunity we contracted to have made for us 50 pumps as shown in the adjoining cut. We are using one of them in a cistern, and can testify that it is a good pump, and a special bargain at the price we ask.

Equal to pumps generally sold for \$7 to \$10. Our price is \$4.50 each; 2 for \$8.00. Quantities at very low prices quoted on application.

This pump has an adjustable base and brace, making it very easy to increase or decrease the height of the pump.

It has an improved,

reversible fulcrum or handle-bearer. This fulcrum differs from all others in that it extends downward to the bottom of the reservoir-head, forming a double bearing or support, doing away with the numerous set-screws commonly used on other pumps and which are so unreliable. The handle may be set opposite or at right angles to the spout, or, in fact, in any position.

It has steel bolts and plunger-rod, making it very much stronger and more durable than the ordinary iron bolts and rod generally used in the construction of this class of pumps.

It has an improved siphon spout and reservoir, causing it to throw a smooth, steady stream.

The pump is made with 1½-inch tubing measuring 4 feet to bottom of cylinder. We will include at the retail price 4 feet of tubing additional. Extra tubing, 1½ inch, at 10 cents per foot. Cylinder is iron, not brass lined. A brass-lined cylinder can be furnished for 75c. extra.

It may be used in wells to the depth of 20 to 30 feet, as well as in cisterns.

A \$9.00 Pump for \$4.50. 2 for \$8.00. Superior in every respect. Well-finished and durable. Special prices in quantities.

The A. I. Root Co.,
 Medina, Ohio.

Bicycles

I have done an extensive business in bicycles this summer, and have now on hand a number of second-hand bicycles, taken in trade or used as samples. Either these or new bicycles I will sell for the lowest cash prices, or will take honey or beeswax in exchange. Send for list.

J. A. GREEN, Ottawa, Ill.

CASH FOR BEESWAX

Will pay 26c per lb. cash, or 28c in trade, for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 32c for best selected wax. Old combs will not be accepted under any consideration.

Unless you put your name on the box, and notify us by mail of amount sent, we can not hold ourselves responsible for mistakes. It will not pay as a general thing to send wax by express.

SAVED BY A DREAM.

Farmer Oak setting posts for Page fence is set upon by another agent, with a machine to "make it yourself, just as good," etc., etc., who soon talks him to sleep. He dreams he's back at the World's Fair, almost famished, can't live without a good cup of coffee, quick. Meets stranger with machine, "You buy the green berry, anything cheap, roast carefully grind in this: p-e-r-f-e-c-t-l-y d-e-l-i-c-i-o-u-s." "Oh, yes, of course, you must steep it, and sugar and cream it, takes a little time, but it's so cheap." Here the nightmare kicks the agent off the field and brings farmer O. to his senses, and he'll use the Page.

PAGE WOVEN WIRE FENCE CO., Adrian, Mich.

HONEY COLUMN.

CITY MARKETS.

CHICAGO.—*Honey.*—Honey is not selling fast, and market is nominal. We quote best or fancy, 15; but good No. 1 stock sells at 13@14; dark, 8@10; yellow grades, 9@10. Extracted very dull at 4½@7. The amber or dark grades are in large supply. Beeswax, 28@30.

R. A. BURNETT & Co.,
Oct. 22. 163 So. Water St., Chicago, Ill.

CLEVELAND.—*Honey.*—There is no material change in our market since we quoted you on October 8. Fancy white comb in 1-lb. sections selling at 17c; No. 1 white, 15@16; choice, 14; buckwheat, 12. Extracted, white, 7@8; light amber, 6. Beeswax, 26@28.

WILLIAMS BROS.,
Oct. 19. 80 & 82 Broadway, Cleveland, O.

KANSAS CITY.—*Honey.*—We quote No. 1 white 1-lb. comb, 13@14; No. 2, 11@12; No. 1 amber, 12; No. 2, 8@10. Extracted, white, 6@6½; amber, 5@5½; dark, 4@4½. Beeswax, 22@25.

C. C. CLEMONS & Co.,
Oct. 21. Kansas City, Mo.

BUFFALO.—*Honey.*—Fancy honey is in very light receipt, and sells readily at 16@17; choice, 14@15; Buckwheat, 10@11. Clover honey could be placed to good advantage in our market. We should be pleased to correspond with those that have some. Beeswax, 28@30. Very little demand for extracted here at present.

BATTESON & Co.,
Oct. 19. Buffalo, N. Y.

BOSTON.—*Honey.*—Comb honey is in good demand and supply at 14@15; extracted, 5@6. California comb is selling well, and has a tendency to keep down the price of Vermont.

E. E. BLAKE & Co.,
Oct. 21. Boston, Mass.

CHICAGO.—*Honey.*—We have closed out three cars of California comb honey, also a number of shipments from near-by States. We are in good position to sell your fancy comb honey at the following wholesale prices: Fancy white 1-lb. sections, 14; No. 1 white, 13; amber, 12@12½; buckwheat, 10. Extracted, as to quality and style of package, 5@6½. Beeswax, 30.

S. T. FISH & Co.,
Oct. 19. 189 South Water St., Chicago, Ill.

ALBANY.—*Honey.*—Receipts of comb honey are large, especially of buckwheat; but with a brisk demand stock is moving off rapidly. There is also more clover coming forward than we expected, but quality is inferior to last season. We quote clover 13@15; buckwheat and mixed, 10@11. Extracted is plentiful, and selling at 5½@7.

CHAS. McCULLOCH & Co.,
Oct. 22. Albany, N. Y.

PHILADELPHIA.—*Honey.*—Honey has advanced in this market, with prospect of still higher advance. Comb honey sells quickly, and pure white-clover extracted sells on sight. We quote comb, dark, 10@11; choice, 14@15; fancy, 16. Extracted, 5@6; New York white-clover, 6½; western white-clover, 7½@8. Beeswax, x, 27.

WM. A. SELSER,
Oct. 22. No. 10 Vine St., Philadelphia, Pa.

NEW YORK.—*Honey.*—We have a good demand for comb honey, especially fancy grades, and it finds ready sales at the following prices: Fancy white 1-lb. glassed or in paper boxes, 15; unglassed, 14; fair white, glassed or in paper boxes, 12@13; unglassed, 11@12; buckwheat, glassed or in paper boxes, 10@11; unglassed, 9@10. No 2-lb. sections on the market, and no demand for any. Extracted is rather inactive of late, with a large supply. We quote: California, 5½@6; white-clover or basswood, 6; southern, 45@55 per gallon, according to quality. Beeswax dull at 27@28 for average quality.

HILBRETH BROS. & SEGELKEN,
Oct. 23. 28 & 30 West Broadway, New York.

SAN FRANCISCO.—*Honey.*—Extracted, light amber, 4½; white, 5½. Comb, 1-lb. frame, white, 8@10. Beeswax is scarce at 26@27.

HENRY SCHACHT,
Oct. 16. San Francisco, Cal.

DENVER.—*Honey.*—Not much change in our honey market. We quote No. 1 comb in 1-lb. sections, suitable for our cartons, 10@11c. Extracted, No. 1 white, in 60-lb. cans, two in a case, 5@6c. Beeswax, 20@25c.

Farmers bringing in small lots of honey and selling for any price offered them demoralizes our local market.

R. K. & J. C. FRISBEE,
Denver, Col., Oct. 22. Denver, Col.

KANSAS CITY.—*Honey.*—Comb honey in good demand. No. 1 white, 14@15; 2-lbs, 12@13; No. 1 amber, 11@12; No. 2, 8@10. Extracted, white, 6@6½; amber, 5@5½; dark, 4½. Beeswax, 20@25.

HAMBLIN & BEARSS,
Oct. 22. Kansas City, Mo.

CINCINNATI.—*Honey.*—Nothing new in the market since our last. Supplies of all kinds are rather scarce, yet the arrivals find a ready sale. Choice white comb sells at 14@16 in a jobbing way. Extracted, 4@7 on arrival. There is a good demand for beeswax at 20@25 for good to choice yellow.

CHAS. F. MUTH & SON,
Oct. 23. Cincinnati, O.

FOR SALE.—California water-white extracted honey, in 60-lb. cans, 2 cans in a case, at 6½c per lb. The honey is a very nice flavor, and should satisfy the most fastidious trade.

S. T. FISH & Co.,
Chicago, Ill.

FOR SALE.—30 boxes nice extracted honey, 2 60-lb. cans in a box; price 7c per lb.

JNO. A. THORNTON, Lima, Ill.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from clover (tinted), 6c. Samples, 8c.

OLIVER FOSTER, Las Animas, Col.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty.

J. P. IVY,
Secretary Bee-keepers' Association,
Phoenix, Maricopa Co., Arizona.

WANTED.—A quantity of white-clover and basswood honey. Must be *gilt-edge* and *cheap*. Send samples and prices to

W. E. SKINNER, Takoma Park, D. C.

WANTED.—To buy quantity lots of fancy comb honey. Also to sell water-white extracted honey in 60-lb. cans.

B. WALKER, Evart, Mich.

FOR SALE.—Buckwheat and amber extracted honey in half-barrels, about 150 lbs. each; well ripened. Prices on application.

J. I. PARENT,
Birchton, Saratoga Co., N. Y.

FOR SALE.—1200 lbs. of honey, in 60-lb. square cans, 6½ cts. per lb., f.o.b. cars here. Sample by mail.

R. H. BAILEY,
195t Ausable Forks, Essex Co., N. Y.

FOR SALE.—We have 14,000 lbs. of choice white extracted honey, in barrels of about 400 lbs., at 6 cts. per lb., f.o.b. cars at apiary. Sample mail for 8 cts. in stamps.

THE CROSBY CO.,
San Mateo, Fla.

Extracted honey in barrels at 6½ cts., or in 60-lb. pails at 7c.

CHAS. DADANT & SON,
Hamilton, Hancock Co., Ill.

FOR SALE.—Utah comb honey, 1-lb. sections, 24-section cans (honey white and package very desirable) at 13 cents per pound. Cash before shipment. This is a chance for some of our bee-keepers, if they want to buy.

S. T. FISH & Co., Chicago, Ill.

EDITOR GLEANINGS.—Please allow us to explain why we offer comb honey at 13 cents per lb. This Utah honey is very fancy. The association sent their cars to this market, and we bought it and are making a small profit on the above sale. Thinking that some bee-keepers might want to buy, and wishing to show them that we are willing to offer at fair margin, we give the adv't. We must have cash before shipment, as we can not open accounts with bee-keepers. As a rule, they have no commercial rating, and we have no guide by which to know that they are entitled to credit.

CONVENTION NOTICE.

The annual meeting of the Illinois State Bee-keepers' Association will be held at the Statehouse, Springfield, Nov. 19, 20. The Odd Fellows of Illinois hold their grand encampment, beginning on the 19th; and we have it from their committee on railroads that they have secured open rates of a fare and a third—that is, a round-trip ticket—is to be purchased at starting-point, anywhere in the State, for 1½ fare. The special meeting of our association will be held at Chicago, at the New Briggs Hotel, Jan. 9, 10, 1896. As this is the occasion of the National Cycle Show, we can get reduced rates to that meeting. Further particulars later. Jas. A. Stone, Sec., Bradfordton, Ill.

Winter Losses

etc., etc. Successful wintering comes from a proper combination of different conditions. For clear, concise, comprehensive conclusions upon these all important points, consult "**Advanced Bee Culture**," Five of its thirty-two chapters treat as many different phases of the wintering problem. Price of the book, 50 cts. The **Review** one year and the book for \$1.25. New subscribers get balance of this year free. I can still furnish queens by return mail at \$1.00 each, or \$5.00 for six. One queen and the **Review** for \$1.50. Queen and book, \$1.25. Queen, **Review**, and book, \$2.00.

W. Z. HUTCHINSON, Flint, Michigan.

THE TORONTO CONVENTION REPORT FREE!

A Full Report of the Proceedings of the North American convention held at Toronto, Canada, will appear in the *weekly American Bee Journal* immediately after the meeting, Sept. 4, 5, and 6. The first installment will be in the number for Sept. 19. If not now a subscriber, you can have that Report free by sending \$1.00 now for the *American Bee Journal* for 1896, as we will "throw in" the balance of the year 1895, beginning with Sept. 19, to new subscribers. Think of it! over 15 months (or nearly 70 numbers) of the old *American Bee Journal* for only \$1.00! Sample copy of *Bee Journal* free.

And, besides all that, each new subscriber will receive a free copy of the 160 page book, "Bees and Honey." Better send on your dollar at once, and join the procession. Mention this paper, please.

No. 21.

STRAY STRAWS

FROM DR. C. C. MILLER.

A GLORIOUS ENDING was that of our grand old friend father Langstroth.

FREEMAN POTATOES have done well here, and what beauties they are! Rural New-Yorker No. 2 is also fine.

IN THE DISCUSSION as to five-banders, the fact is not as generally recognized as it should be that there are five-banders and five-banders. It seems that some of them are Italians, others not. Why should they be alike?

THE FALL YIELD in this locality doesn't usually amount to much. I think it was better this fall than ever before. Now, if the bees that have got into the way of storing will only keep in the same mind next spring!

STRAWBERRY-PLANTS kept in hills is a superannuated plan in the West, voted out years ago. But latterly it seems to be coming in again, and I saw at Freeport a fine bed kept in hills. Mr. Cotta claimed it was little more work than the matted-row system.

MY FIRST MEETING with father Langstroth was at Cincinnati in the winter of 1872-3. He very kindly called to see me at my office where I was helping to get up the first of the great May Musical Festivals under Theodore Thomas.

YOU CAN GUESS pretty closely at the amount of stores in a hive by looking at the tops of the combs; but you can come closer to it by weighing each hive, and you can do it in less time. Make abundant allowance in every hive for weight of pollen and extra weight of old combs.

LET US KNOW MORE about rape. Do others find it as profitable for forage as Jas. Pratt? In Germany bees are moved to the rape-fields. Is the Dwarf Essex also good for bees? [I should like to have our readers who may have had experience along these lines speak out.—ED.]

LANGSTROTH AND QUINBY are both gone; but the Germans still have their Langstroth, the revered Dzierzon. Only three of the 40 great wander-conventions has he missed since their commencement in 1850.

IN THAT DESCRIPTION of alfalfa on p. 778, doesn't friend Taylor mean it looks like *sweet* instead of *red* clover? When not in blossom, alfalfa is very hard to tell from sweet clover. Just look for sweet clover with purple blossoms or snail-like seed-pods and you'll have alfalfa. Can't miss it.

A MAN IS CRUEL to his team who allows a weight of 200 pounds of frozen mud to remain on the wheels of his wagon. He's cruel to himself if he allows himself to carry around 25 or 50 pounds of useless fat. Since reducing my weight 20 pounds, it's a good deal easier to carry my carcass around.

EVEN THOUGH not interested in shipping queens long distances, one can not help admiring the adapting of means to ends in that cage pictured on p. 774. Few lines of business set to thinking about and planning new implements and methods more than bee-keeping, and few lines contain brighter thinkers and planners.

"ALL IMPURITIES are left behind when water is turned into steam," says S. S. Butler, p. 770. I don't know about that. When a pot of meat is cooking, the water is turned into steam, but that steam has a pretty strong odor, and carries with it something more than pure water. If boiling kills all poisonous germs, can evaporation do more?

MORE AND MORE I come to the view that I don't want to see sweet clover grow six feet high. I think more honey in the long run will be had from it if it is kept cut down or eaten down so that it never gets more than two or three feet high. [I think you are right—at least, the clover that stock browse down seems to be more thickly covered with bees.—ED.]

STOP MY PAPER! It isn't a safe thing to be lying around where children can read it. When J. P. Israel talked about cross-eyed bees that

was bad enough; but when Rambler talks about pulling the bottom out of a well, that's "lying around" too much. Why, you can't pull the bottom out of a well, and bees never get cross-eyed. Stop my paper!

MY PREJUDICE is decidedly in favor of five-banders on account of their beauty, and I wish with all my heart that we could rely upon profit in exact proportion to beauty; but facts can not be ignored, and I suppose we must give up that many of the five-banders are inferior. The charge as to poor wintering seems pretty fully established.

SOMEHOW that straw at the head of the second column, Oct. 15, seems to have had its head knocked off. But the heads of straws have no grain in them anyway. [We plead not guilty here. I don't agree. The "straws" very often—yes, generally—have bigger heads with kernels in them than the Heads of Grain. In reality this department should be christened Heads of Grain, and the other now bearing that cognomen, "Bundles of Straw," but you know I don't believe in changing names.—ED.]

LET UP, Mr. Editor, on calling my language slang. If you will look in the dictionary you will find that "let up" is not slang but colloquial. I am surprised to find that "catch on" is also colloquial. But I like apprehend or "understand" better. I'm rather in favor of using slang when it expresses what can not be expressed by straight English. [So am I; but it strikes me that much that has come to be regarded as colloquial is really slang. As to "catch on," it expresses more to me than "understand." The latter is too tame.—ED.]

MY CONCLUSIONS don't entirely agree with those of J. P. Israel, p. 771. I think foundation in sections will keep a long time without losing any of its "internal arrangements," if kept from the bees; but if left too long in the hive when no honey is gathered, especially late in the season, its "external arrangements" are so disarranged by the bees that they'll not use it. I have thousands of sections filled with foundation. [How is this, friends? Let us have testimony from a good many others. The proper answer to this may mean a good deal to some.—ED.]

"HE'LL REDUCE his weight till he reduces himself into the grave," is the remark one of my auditors made when I read the first sentence on p. 782. [No, he won't. He is gaining now, and your humble servant on the same treatment is now gaining three pounds a week, and I shall soon be in full flesh again. My normal weight in health is 140 lbs. After being on the diet for a few weeks it got down to 117. "Alarming," you say; but Dr. Lewis told me I must expect to lose weight; that I must, as it were, throw away useless waste material and build anew. Am I doing it yet? Yes, str.—ED.]

NUMBER OF BEES TO THE POUND.

DO BEES PREFER NEW OR OLD COMBS?

By Philip J. Baldensperger.

Mr. Root:—The question seems to agitate bee-keepers to some extent as to how many bees there are to the pound; how many pounds to the swarm; how many eggs a queen lays a day; bees carrying eggs; and old or new foundation, which preferred? We all know by experience, and by having read in divers periodicals and books, that the number of bees per pound differs according to race, and more especially their condition when weighed, whether full or empty, or, I may say, very empty, and perhaps an infinity of conditions—very full, half full, and so on. Mr. A. I. Root, if I remember well, some years ago said in GLEANINGS that 25,000 bees in a colony was what he deemed about right. In your footnote, p. 585, Aug. 1, 1895, you give two conditions—4500 to 5000 per pound before swarming, and 3000 to 3500 when filled with honey. This last number is about what Simmins and Cheshire find in a pound, while your first number, 5000, is given by the Abbé Voirnot—perhaps one of the most eminent French bee-keepers. Cheshire, Vol. II., p. 263, put 10,300 bees to the pound; and he found that 3000 *dark* bees filled with honey make a pound, and 4500 to 5000 *yellow* bees per pound, filled. Of course, colonies may vary greatly, from 4 to 10 lbs., while I think an average good colony, swarmed out in fair condition in spring, when flowers are abundant, would weigh 7 or 8 lbs. Here, again, opinions differ very widely, I may say; for Mr. Hyde, on p. 585, says 8 lbs. of 3000 bees each equals 24,000 bees; and you indorse his opinion, which, I am glad to say, I suppose is nearer the truth than any other figures.

Authorities on bees differ greatly as to the number of bees in a hive. Mr. J. Hewitt, in the *British Bee Journal* for July 1, 1884, says 76,000 worker-bees, and believes that something like 200,000 bees in a hive at a time may be found. Abbé Martin says 100,000 workers, which figures he arrives at by multiplying numbers which have almost "become, in bee-keepers' minds, an established error.

You can hardly see a book or article but you read of 3000 eggs a day. Suppose, now, these 3000 eggs are to be multiplied by 21; that makes 63,000, and this goes on. Another one says it is known that one bee brings in $\frac{1}{7}$ of a gram, and remains 10 minutes on a trip, and works 8 hours a day. This equals so many pounds; hence so many bees. But there are a great many *but*s which must always be remembered; for neither does a queen lay 3000 eggs *every* day, nor is the

laying at all regular; nor do bees fly out at regular intervals; and still much less do they come in so, nor with uniform loads; nor do they live uniformly six or eight weeks during the working-time, nor 6 to 8 months during winter, or, at least, during the time of repose. I will give a few notes later on, collated during many years of close observation as to numbers. Let me here say, that, as nearly as I could make out, 35,000 to 40,000 bees is the average of a *colony* — not a *swarm* — note that. A swarm can never be as strong as a colony, as the swarm issuing is part of the *average* colony; thus, a colony ready to swarm may push the queen to laying up to, say, 50,000 workers present; a swarm issues, and 25,000 bees are left in each camp, including, of course, some old bees.

NEW OR OLD COMB.

But now comes another question: Suppose, to start with, we put the 24,000 bees into a hive, according to the condition of the comb. Old comb is, in my opinion, undoubtedly best to begin with; and here Dr. Miller and his correspondents, on page 634, Aug. 15th, agree on one point. Every question has many sides; but especially so with bees; as almost always, whenever a question is set forth, it must be put under certain conditions; thus, in *Stray Straws*, June 15th, "Please," says, Dr. M., "keep watch and tell us whether a queen prefers to lay in new or old combs; also which the bees prefer to store in." Immediately we would put the question to ourselves as to whether the queen is surrounded by blacks or Eastern or Ligurian bees, and at what time of year. My experience leads me to say that a swarm newly hived, or a colony in fair condition, with old and young bees hatching, working on old comb, will draw out comb foundation introduced into the brood-nest, over night, and one will be very sure to find the flat comb foundation, introduced in the evening, containing eggs in the center about 7 or 8 o'clock next morning; also some drops of honey, and even pollen, near the top, provided it is during a good honey-flow, and in spring. Of course, it pleases the eye, when looking in next morning, to find the yellow foundation turned into an almost snow-white comb, and inhabited by bees, as though it had always been there; and beginners in general, and even bee-keepers of many years' experience, not carefully examining the question, are led to believe that bees prefer the new combs, and simply because it pleased their sight and feeling as to durability.

In France the opinion has been held by many, that, between 4 and 6 years, the combs are too old to be of any use to the bees, as the cells are by that time too small, on account of the successive generations of bees hatching in them, and because they "darken the honey." This last opinion is due to the dark sealings. Every one knows that bees will seal their honey very near the color of the comb; and here the races

give different color to the sealings of honey. I have frames and combs that have been in use ever since I began bee-keeping; and when we first started we bought jar hives which had been used many years, so I know that twenty-year-old comb is very good, and I would not call it old; nor am I now discarding any.

A correspondent of mine bitterly laments my having sent him dark comb with the colonies he ordered of me, although I had to explain to him (a man who boasts of twenty years' experience in bee-keeping) that old comb is better than new to start with a nucleus; and, secondly, that on no condition will I send newly built comb, loaded with bees and brood and honey, through the mails, and that for the sake of both of us; for although the seller always guarantees safe arrival of his queens, every one knows how disagreeable it is to receive a queen or colony in bad condition. He'll have to wait a few days more, perhaps a few weeks; but he wanted to start at once, right into the honey-flow then abounding in his or her locality. The bees are obliged to secrete wax, many writers claim; but, on the other hand, they ought to have said, "In spring, bees will secrete wax with great facility, and to some extent must do so." This would be correct. This is chiefly from such men as like to combat mobilists; or, if they get to be mobilists, comb-foundation manufacturers; but bees can build comb foundation, and secrete wax, to a small extent, almost every spring of the year, and not more. Suppose, for an instant, those writers to be correct in their views; what do they do with the stock of bees in a tree, sending out swarms year after year, and good comb-builders in the bargain, without ever building any comb in the old locality? They breed in the perhaps half-century-old comb, store honey, and, in years of scarcity, remain there. The wax-secreting organs are not at all changed in the succeeding generations, because, for at least 18 months, no swarm issued; and, consequently, no wax was secreted; but let us for an instant follow a swarm, issued April 1, hived entirely on foundation, as there was no old comb to spare. In about 15 days, during a fair honey-flow, the bees have drawn out 10 to 15 combs; and let us suppose that honey is coming in. We add a story, and 10 or 12 combs are built. The wax-secreting organs have been exercising their functions to their fullest extent. At the end of May, of course, not a single bee of wax-secreting memory is living, and the generation now filling the hive is from 1 to 40 days old. Not a single bee has had any occasion to secrete wax, because the hive is complete. The first-hatched bees are rapidly dying off. About the end of June, 60,000 or 70,000 bees will have passed away, having carried in honey and pollen, and water-nursed the bees, but never secreted any wax. The extractor is worked as often as necessary, giving the

bees a chance to make continual visits, and many more chances to secrete wax; to repair the wear and tear caused by uncapping and many other operations.

As a rule, bees will not build foundation in summer during a very light honey-flow, provided a good number of old combs are given to the hive. I have tried it time and again, putting in a sheet of foundation to every three or four old combs, to find, a fortnight later, the old combs filled with honey—often, also, with brood, and the foundation left untouched in the middle, even though on some occasions it would be introduced right into the brood-nest, and left untouched, or a few cells be drawn out in the center, "*par acquit de conscience*," eggs laid, and sealed, and that was all. Honey is generally stored right above the patches of brood. The bigger the combs, the more concentrated you may find the brood and honey; while with smaller combs, honey is discarded in cases of a fast-laying prolific queen; but, again, in spring, as the season advances, honey is brought nearer; the patches of brood are rounded to take the winter-clustering form, and honey is put around, and old comb is utilized in preference, as being more firm. Perhaps, also, the dark color is preferred by bees. They do not want any light inside the hive, and so, perhaps, discard the light-colored comb at the approach of winter. As a rule, of course, there may be exceptions.

Nice, France.

[You will find an article bearing on this same subject, on page 699, Sept. 15th issue. Thanks for the additional light you have given us.—Ed.]

RAMBLE 142.

CROSSING THE TEHACHAPAI MOUNTAINS.

By Rambler.

In the Tejon Pass we crossed a portion of the great Beal Ranch, containing 350,000 acres. Gen. Beal, of the U. S. Army, and at one time Surveyor-General of the State, accrued to himself the above territory. The method of accruing it, it is said, was intensely crooked; but as the general has exchanged the title to the 350,000 acres for a little parcel of ground 2x6 feet, and gone to the country where the crooked shall be made straight, I do not feel like accusing him of misdeeds now. Upon the ranch are 15,000 head of cattle, hundreds of horses, and hogs; in the mountainous portions grizzly and black bears, deer, antelopes, and much smaller game. It was a game country, and Bro. Wilder would have explored its ragged recesses at any other season.

The Tejon Pass, for the greater part of the way, is a rough and ragged canyon. Reina had regained the control of her foot again. She seemed to reserve her lameness for Sunday

travel only; and before night we arrived at the adobe home of our poetical Irishman, and we camped in the park of noble oaks that surround his house. In the evening we gathered around a roaring fire that sent the sparks up the chimney from a capacious fireplace; and how true it is with us lonely bachelors that "A fellow feeling makes one wondrous kind"! Our friend the poet was a good conversationalist, and the pleasures of the evening tripped lightly along until there came an ominous knock at the door. "Come in!!" cheerily said our host. The door opened, and a short, thick-set, powerfully built, black-faced, black-eyed, black-bearded Mexican appeared. "Come in. José" (Ho-say). They both laughed, and clasped hands like the dearest of friends. José unbuttoned his coat, and from an inner pocket he pulled a long black bottle and placed it on the table. The men again laughed, and clasped hands.

THE POET'S HOME IN TEJON PASS.

Our host, who had been somewhat sedate in conversation, was now visibly enlivened. The bottle rested not long upon the table; the cork was drawn and glasses filled. As guests we were offered a generous allowance; but Bro. Wilder and I could not afford even here, in the cabin of our convivial poet, to break over our rules of temperance, so we politely declined. José and our host, however, attacked the bottle and clinked their glasses together for health. The clinks became quite frequent, José quite musical, and our host poetical. We observed that the performance would last until a late hour, and we bade the performers good night and sought our tent and our slumbers.

We were aroused some hours later by voices near our tent singing a farewell song—softly, then swelling in harmony, José's deep bass voice and the poet's tenor. For a full half-

hour this tender farewell trembled wierdly upon the night air. The agony of farewell was enough to sever two loving souls a thousand miles apart and for years; but José lived only three miles down the canyon, and expected to see his boon companion the next morning. The agony of parting ended at last, and José rattled off down the canyon with his horse and cart, and we were left again in quietness. In the morning our poet host was not so lively, and perhaps he was a little shame-faced before us. We learned from him that he was a voluntary exile from his wife and children, and had not seen them for three years, and they lived in a moderate city less than a hundred miles from his lonely retreat. His abilities were such that he had held county trusts, and his poetical gems had assumed book form which had met with favorable sales. His family were bright and well educated, and moved in good society; "and," said he in a tone of sadness, "you saw last night why I live this lonely life." His convivial habits when at home were continually bringing disgrace upon his family. I relate the incident as the best kind of a temperance lecture; and we are again admonished by it to "taste not, touch not, handle not." Our poet could handle bees, and had tried bee-keeping; but his habits and the business did not agree. The bees, it seems, had a certain love for him; for in the morning he showed us some of the oak-trees that were around his cabin, the hollows of which were occupied by bees. Seven trees bore burdens of sweetness, and he said there were several more in the canyon, but no near bee-keepers.

Our farewell was not so tedious or musical as the one of the previous evening. After our brief parting compliments we continued up the canyon and were soon upon the summit of the Tehachapai range of mountains, about 4000 feet above sea-level.

Our route was now down grade, and our ponies made good time into Antelope Valley, so named from the immense herds of antelope that only a few years ago roamed the plains. Now the bands are few and scattering.

At Neenach we found one store, a school-house, and one residence. They had something of a trade from the surrounding country. We had an excellent opportunity to observe, for we sat around the stove all day. A rain had taken possession of the country, and we were thus delayed. We diligently inquired of the ranchers and hunters in relation to the honey resources of the valley, and found varying opinions in relation thereto. The valley is very broad, and the bee-men seemed to be located in the distant foot-hills, where some of our informants said large yields of honey were produced.

The next morning, though the skies were threatening, we pushed on again toward Elisa-

beth Lake. We passed through a new experience on the way. The shepherds were tending their flocks upon the hillsides, and they were in trouble. As we traveled up a long grade we saw here and there the carcass of a dead sheep; and as we neared the main herd the dead sheep became more plentiful. The cold storm saturated their woolly coat, and the weaker ones soon became chilled, and dropped by the way. As soon as a sheep would drop, its throat was cut and its hide stripped off and packed upon a burro. Several burros were thus laden. The sheep-men said they had a flock of 4000 sheep, and would think themselves lucky if they could get out of the hills with 3000. So sheep-men have their losses as well as the bee-men.

When we came through the narrow pass above Elisabeth Lake we were met by a fierce wind and rain. It seemed as though the elements were opposed to our further progress. We were soon drenched to the skin. The little lake was lashed by the fury of the storm, and we were greatly pleased to find shelter from the storm at the stage station. We here found again a generous Missourian, who had lived upon the shores of the lake for many years. He had joined himself to the country in a truly heroic spirit, and had not only grown up with it but had added largely to its population by marrying a Spanish woman; and the result was a houseful of mongrels. The rain had driven them all into the house, with a few of the neighbors thrown in, and it was a motley crowd that gathered around the ample fireplace and its generous heat. Bro. Wilder and I were so thoroughly wet we were given a warm corner where we proceeded to dry out our garments. It was of interest to note that two full-grown señoritas flashed glances from their dark eyes toward my partner. I was pleased to observe that he was not especially taken with the style of half-breed beauty.

After getting used to the situation I noticed two young American ladies in a far corner. They were very quiet, and did not seem to mingle much with the rest of the occupants of the room. I noticed some of those tell-tale lines running from the corners of the eyes, and others running down somewhat slanting from the corners of the mouth. The hair was trained down to a smooth habit; the dresses were plain striped calico, about eight-cent goods, and possessed a little narrow white collar, starched. In the lap was a checkered gingham apron with white pockets on the right and left, duly puckered. The tendency of the arms was toward an akimbo habit, and there was a severe cast to the countenance, a frigid dignity to the general figure. I could almost see hickory rods in their hands, and with some solicitude I edged my chair up to the side of our host, and, pointing my thumb over toward the

corner, I whispered in his ear, "Schoolma'ams?" "Yes, schoolmoms," said he, in a stage whisper, "both on 'em; sistern; one teaches our school; the other, the one over in Grimes Canyon. I tell yer, that oldest one, the one that teaches our school, has the most sassafras about her, though."

Partner caught the word "schoolmom," and it seemed to electrify him at once. I was again in a state of consternation; and, while he was frantically trying to dry all sides of his body at once, I felt greatly relieved to see the schoolma'ams retire to an inner room; the girl with a sassafras reputation brought up the rear in good order. A sly word to our host, and he kept them corralled in that obscure portion of the house until we departed early the next morning.

Our Missourian had at one time been a bee-keeper to the extent of a hundred colonies. He said that the locality was too cold and windy, and he could get but little honey, and so gave up business. I reflected upon the matter, and came to the conclusion that a man who owned several hundred head of cattle, and could not bring down from the hills one cow to provide milk for his numerous youngsters, would not succeed with bees in the best of pasturage. He lacked what he applied to the schoolma'am—sassafras.

THE T SUPER VS. THE SECTION-HOLDER DEVICE.

AN EXCHANGE OF LAST SHOTS.

By Dr. C. C. Miller.

I may as well confess, Mr. Editor, that you have made on page 517 a better plea for the section-holder than I supposed was possible; and I am much obliged to you for putting your plea in definite, orderly shape. I'll try to accept the truth that is given, and show, if I can, wherein there may be error.

Your first argument is one that should have weight; and if you find a large number using section-holders or modifications of them because, after trying both, they prefer them to T supers, that should make a heavy score in favor of section-holders. At the same time, it must be remembered that one modification of the section-holder (the wide frame) is a good deal older than the T super, and many are using it who have probably never tried the latter. Indeed, I suppose there are many who have never tried either of them, and are, perhaps, wondering why we are quarreling as to which is the better of two articles, neither of which they would have for their own use.

You make six distinct claims as to the superiority of the section-holder. I'll take them in order:

In No. 1 you say, "In some localities it is desirable to shift the outside row of sections to the

center, and *vice versa*." I think that isn't true. Now, mind you, I'm not saying you're a liar, only I don't believe it is true, just as I don't believe some of the other things you say, although you *may* be right and I wrong. And this brings up a proper subject upon which to have light thrown. We ought to know whether it is or is not desirable to have sections change places. It is possible that I may be convinced—and, what is more to the point, that others may be convinced—that, in certain places, it's a good thing to jump sections. If you've got any light, turn it on. At present, No. 1, I think, stands "not proven." If that point be proven, I'll go farther than you, and say that the section-holder is well fitted for such interchanging, and the T super isn't fitted for it at all.

No. 2 stands. I'd rather have fewer loose pieces than the T super has.

No. 3 is a case of special pleading that won't stand; for we're not talking about the abuse but the proper use of things; and you admit that, with proper use, sections are square in T supers. I can prove by your own words that the slats on which sections rest in section-holders will sag, and I think you know that T tins do not sag. That makes it so that proper use will result in none but square sections in the T super, and at least some sections a little out of square in the section-holder.

No. 4 I'm willing to admit, in plain Roman letters; but when you call the advantage *important*, in italics, that's carrying it too far.

No. 5 is another case of special pleading mixed with what I believe to be erroneous statement. I very much doubt that the great majority of bee-keepers put sections on the market unscraped. Perhaps a better way to put it is to say that I think the majority of sections put on the market are scraped. Even if what you say were true, it's not the right thing to tell a beginner he should use an inferior article because it best fits careless and slovenly bee-keepers; for no less an authority than the A B C says, "In order to make sections present a clean marketable appearance, all propolis should be scraped off."

But this difference you are speaking of, be it more or less, is only on the edges of the section; and the important part to scrape and have clean is the top, and I suppose you would hardly say there is any difference as to tops in the two supers.

No. 6 contains a view that you may be excused for holding, on account of your relying on antiquated authorities. Allow me to lay my modesty aside long enough to say that the man who wrote "A Year among the Bees" didn't know as much about producing comb honey as I do; and he didn't know the best way to engineer a T super. None of that complicated machinery of which you speak is used except a single board as a follower to push out the sec-

tions. You say, "The section-holder arrangement may be emptied by simply removing a wedge or tightening-strip, and then all are practically loose." That's a fine example of the way to teach an error by stating a truth. The words you say are strictly true; but the inference likely to be drawn—namely, that something quite different rules with the T super—is the reverse of true; for loosening the very same wedge in the T super leaves the sections just as loose, and the manner of emptying is just as "self-evident," in one case as in the other. So No. 6 falls to the ground with a "sickening thud." But I forgive your attempt to deceive in No. 6. It doesn't come so much from a bad heart as from blindly following the teachings of a man so far behind the times as the writer of "A Year among the Bees."

As to the matter of looks of the T super with one or four cleats, you are not paying a very high compliment to the good sense of bee-keepers when you say that 99 in 100 would reject the thing because of its looks. I have a better opinion of them. But when you say, "The outside cleats on both ends are intended in lieu of hand-holes," I give in. I think I like the four cleats.

You repeat one of your former arguments, and thus compel me to repeat my reply. No. I am not as much accustomed to the section-holder as to the T super; but it doesn't necessarily follow from that that I can't see the advantages in something new: and the proof of that lies in the fact that, when I knew as much of wide frames as I now do of T supers, and as little of T supers as I now do of section-holders, I nevertheless changed from the old to the new, and am I not just as likely to see advantages in a new thing again, if those advantages really exist?

And speaking of wide frames reminds me that I ought to remind you that you have not told us what advantage the section-holder has over the old wide frame. If it's no better than the wide frame, and the T super is better, does it not logically follow that the T super is better than the section-holder?

Now I think I'll leave you to sum up the differences between us and agree not to talk back, asking you not to forget that any width of section can be used in the T super, and only one width in the section-holder. I don't know for certain what width is best. Do you? After using many thousands $1\frac{1}{2}$ wide I changed to $1\frac{1}{8}$, and I should very much dislike, by adopting a section-holder, to contract to use nothing narrower than $1\frac{1}{8}$ for the rest of my life.

Marengo, Ill.

[Then you don't admit proposition No. 1. Suppose you turn to p. 741, Doolittle's article, and see how he manipulates rows of sections. Remember that he and a host of others use single-tier wide frames; and one of the main reasons, if I am correct, why they use them is the

facility afforded in transposing rows of sections over the top of the brood-nest. The only difference between these and section-holders is in the use of a top-bar. Knowing in the first place that a large number were following Doolittle in the use of what is now known as the Doolittle surplus arrangement, we adopted the section-holder device, which is, to all intents and purposes, the same thing. P. L. Viallon, once the leading bee-man of the South, was, and for aught I know is now, an earnest advocate of the Doolittle arrangement. With either this or the section-holder proper, and intelligent manipulation, we can avoid hundreds of pounds of unfinished sections; and this may mean profit as against actual loss.

Before I leave proposition No. 1 I must say that our position as supply-dealers and publishers puts us where we can see what bee-keepers are using and calling for. The T super has had its day among the great majority of bee-keepers, no matter how well a few, like yourself and some others, may like it. Why? Among other reasons, because it favors the production of unfinished sections—something that can be more easily avoided with single-tier wide frames or section-holders.

If No. 2 stands we will pass on to No. 3. I contend this is not a case of special pleading. You say we are not talking about the abuse but the proper use of a thing. Isn't it rather this way? In the language of President Cleveland, we are "confronted by a condition, not a theory." The "theory" is, that sections in T supers can be held square by the use of a lot of extra fixings. The "condition" is, that the majority of bee-keepers (not won't but don't) fuss with these strips of wood that require so much care in adjusting. Bee-keepers do not, as a rule, stop to take the "diamond" shape out of the sections in T supers, as you would find if you bought honey by the ton and carload from all over the country as we do. Neither do they scrape those same sections.

This brings us to point No. 5; and here again we are confronted with a "condition;" and that condition is the most satisfactorily met by the section-holder.

Suppose we say that our present spelling is an abuse in the use of superfluous letters. We can not ignore that abuse as you would have us do in the case of the non-scraping propensity of the majority of bee-keepers. We must take it as it is, as we do every day in spelling. If the section-holder, when keyed up with slotted wood separators, gives cleaner sections without scraping, and truer in shape, then it is the better arrangement. As to your other points, I would refer the reader to my former statements to which yours are in reply.—Ed.]

THE PURITY OF CALIFORNIA HONEY.

THAT HALF THE HONEY PRODUCED BY CALIFORNIA HAS BEEN ADULTERATED WITH GLUCOSE, AND SENT EAST, NOT TRUE.

By Geo. W. Brodbeck.

Friend Root:—I am very much disposed to take exception to the publication of such a sweeping statement as the one made by C. W. Dayton, in GLEANINGS, page 729, that "half the honey produced by California has been adulterated with glucose, and sent east by a few, if not very few, wholesale firms." A statement of this kind, and of which you your-

self say, "I can not believe is true," ought to be consigned to the waste-basket unless accompanied by at least some substantiating evidence in support of it; and yet this does not contain a single shadow of evidence in support of it. In spite of your assertion, "I don't believe it," the very fact of its publication in one of our leading bee-journals will result in a reproduction in other papers, minus your footnote.

Our situation in connection with this case is a rather peculiar one; for, to sum up, we of necessity become the defendants, and the burden of proof is demanded of us, which, as a rule, devolves on the plaintiff; but necessity compels us to avoid any exception to this unusual mode of procedure, and we trust the truth and nothing but the truth will be forthcoming.

Our home market is so limited, and our product some seasons so great in quantity, that our only source of disposal is the honey markets of the East; consequently, whatever is said or done reflecting on our product destroys confidence, thus limiting the demand and lessening the price; and if this is true, any reflection or insinuations as to the purity of California honey, be it true or not true, is a question of vital import to every California bee-keeper.

'Tis true, I have heard something of adulterations in California, and I have endeavored, as far as possible, to sift out and digest these circulating rumors as far as it has been within my power to do so; and, with one exception, I have yet to glean any evidence in support of adulteration in this, the largest honey market in California. You, in all probability, know something in regard to freight rates to this coast, and in consequence can form some idea of probable profit in shipping glucose out here to adulterate honey with (glucose is not manufactured out here), and then reship to the eastern market, and this when honey has been selling as low as $3\frac{1}{4}$ to $3\frac{1}{2}$ cents in any quantity; and as probable gain would be the only inducement to do this, I fail to figure any possible profit at present prices.

Since reading Mr. Dayton's statement I have consumed the greater portion of two days in this city in search of glucosed honey, even going so far as to trespass on the domain of the "exception" referred to, and thus far have failed to find a single ounce of glucosed honey.

From evidence gleaned, I candidly believe that, in years past, when our product commanded a higher price, one establishment in this city was guilty of adulteration; and from this, more than all else, have sprung the rumors of the mythical millions of adulterated honey. Furthermore, allow me to inform you that the last session of our State Assembly passed two laws bearing on the subject of adulteration—one bearing directly on honey, and the other

indirectly, in connection with the "pure food" law, in both cases making it a misdemeanor; and I can assure you that, whenever any evidence of honey adulteration is produced, the Los Angeles County Bee-keepers' Association will see that guilty parties will get their just deserts.

Los Angeles, Cal., Oct. 15.

[The first thought that came to me on reading the item with regard to the extent which California honey was said to be adulterated, in friend Dayton's article, page 729, was that it should be struck out. And then I remembered that I had seen various allusions to the same effect in agricultural papers; and I had heard it whispered around at conventions and elsewhere that California honey was so largely adulterated that it seemed to me it would be better to give the thing some intelligent consideration; that if it should prove to be only a man of straw we could easily knock it over.

I am very glad indeed to get such an explicit, and, as I regard it, satisfactory, denial, of the statement. I am glad, also, to know that there are two good laws in California, bearing on the subject of making the adulteration of honey a misdemeanor. Surely, with the help of the Los Angeles Co. Bee-keepers' Association, and in connection with the Union, we should be able to sift these things down to a pretty fine point. But here is another article from the Rambler:]

CALIFORNIA HONEY NOT ADULTERATED AND SENT EAST.

HOW THE PRODUCT IS MARKETED.

By Rambler.

In Mr. Dayton's article, on page 728, there are several statements with which California bee-keepers can not agree, and one in particular that calls for a word of protest. He uses these words: "It is estimated that one-half the honey produced in California has been adulterated with glucose and *sent east* by a few if not a *very few* wholesale firms."

I have italicized the words open to criticism. It is a bare possibility that half of our honey is adulterated before it reaches the consumer; but if it is, there is insufficient data to support the assertion, and it resolves itself into a mere guess or conjecture. But when Mr. Dayton uses the term "*sent east*," implying that the honey is adulterated to such an extent here in California, I do emphatically protest against the insinuation, and not only say with the editor in the footnote to the article, "I do not believe it," but, while I do not charge the writer with a willful desire to deceive, I can prove that it was too lightly considered.

The honey in all this region is sent east in various ways. A number of producers market their own honey, either through commission houses in the East or by direct sales. There is no suspicion of adulteration, and is none in these shipments. Next a great amount of honey is purchased by local dealers. Every locali-

ty has one or more local buyers. These buyers pay cash to the producer, and the honey is loaded upon the car at the nearest station, and shipped directly east. The scores of carloads of honey that will be shipped from this (San Bernardino) and Riverside Counties, will go directly east, virtually from the producer, and will not even pass through our large trade centers. All of the honey in Ventura and northern Los Angeles Counties is served the same.

Mr. Dayton's remark, "very few," narrows the charge down to certain wholesale firms in Los Angeles. There have been various charges well sustained against certain of these firms and their practice of adulteration; but the reader will readily see that the idea that these few firms adulterate half the honey in California is not only fallacious but ridiculous; and the writer of such a statement must have been laboring under a violent nightmare over the anxiety to get a better price for his honey.

If it were really desired, I could show by railroad statistics that but a small portion of our honey finds its way into the warehouses of the wholesale firms of Los Angeles or even San Francisco.

That our local dealers send out the pure article can be attested to by the A. I. Root Co.; for I know (if they do not) that their carload of California honey was shipped by a local dealer of Riverside.

That there is plenty of work for the Beekeepers' Union to do along this line is not disputed. I believe the present stagnation of our honey markets is, in a certain measure, due to this evil. The hush-up policy will only aggravate the evil by giving the criminal the idea that he can pursue his calling without fear of prosecution.

We have an example before us in the manufacture of oleomargarine butter. Suppose the farmer had adopted the hush-up plan as a remedy for the evil, how much pure butter do you suppose we should find in the markets? Any one can easily answer the question. But the farmers are a strong factor in this country; and when they acted as a unit against the adulteration of their product, legislators were obsequious to their will, and strong laws protect the dairy interests. The bee-keeping interests are weak beside the dairy interests, but need the strong arm of the law quite as much; and that it may be applied with thoroughness and wisdom in behalf of our beloved pursuit is the desire of the Rambler.

Bloomington, Cal., Oct. 12.

[We can testify to the fact, as Rambler says (and he ought to know, for he has traveled all over the State), that a very large portion of the California honey is sent from the producer in that State direct to the buyer in the East. We have several times bought from producers in that way ourselves. Much of the honey is marketed by the bee-keepers' associations. Of

course, the honey may be adulterated after it gets here; but we "wise men of the East" surely ought to be able to keep it pure while it is here.

Rambler's fourth paragraph is somewhat of a clincher, and I regret that it shows that Mr. Dayton, who usually writes very carefully and cautiously, was in this case very indifferent or else careless.—Ed.]

A VALUABLE POINT ON THE HIVE QUESTION.

THE IMPORTANCE OF A LARGE HIVE DURING THE BREEDING-SEASON, AND A CONTRASTED BROOD-NEST FOR THE HONEY-FLOW.

By O. O. Poppleton.

I have watched with some interest whatever has been written on the hive question; and will you allow me to call special attention to what is one of the most valuable points brought out as yet? I refer to the last part of your footnote on p. 731. As you know, I use mainly, for extracting purposes, a large single-story hive in which I can add to or take from the bees one or any number of frames at any time. The few thousands of pounds of comb honey I have taken has been mostly done by giving the bees all the combs they could use in the breeding-season; and then when giving sections I take away all combs except the 8 which contain the most brood? In my mind there is no question whatever that this method gives a larger yield of honey than if only an eight-comb hive is used, or even a ten-comb, if the ten are kept in use all the season. My experience leads me to think that more than ten frames during the breeding-season is preferable with most colonies to using only ten. If I were to rig up for comb-honey raising I would use either a sixteen-frame single-story hive or double eight-frame hives, cutting down in either case to the best eight combs when putting on sections. The possible drawback to this method is that it may tend to increase swarming; but such did not seem to be the case in my experience. It would take a careful comparison of the two methods in the same apiary to determine that point.

I think that the reason why Mr. Earl's small hives (p. 731) gave him the largest yields was due to other unnoted reasons than because of a difference in size of hives. I believe it is almost universally admitted that small hives are not so good as large ones for producing *extracted* honey—the interest in this question of small vs. large hives being confined mostly to producers of comb honey.

There are many times in this Southland when extra-large colonies in very early spring are of less value than are medium-sized ones; but Dr. Miller has no cause whatever to worry about that in his locality. The trouble there is the other way.

If Dr. Miller wishes to induce his queens to

occupy the upper stories he can usually succeed by lifting one or more frames of unsealed brood into the upper one, replacing with empty ones. This is an old and (I suppose) a well-known expedient. The first part of this article answers some of the doctor's questions on page 740.

Stuart, Fla., Oct. 14.

[I regard this article as well considered, and it is pretty hard to get around some of the facts he presents.—ED.]

LOCALITY AS BEARING ON THE HIVE QUESTION.

THE IMPORTANCE OF LARGE HIVES: WHERE LARGE HIVES GIVE THE BEST RESULTS.

By F. L. Thompson.

Mr. E. R. Root:—Mr. Getaz has hit the nail on the head, on p. 742. While you recognize locality, on p. 4 of your catalog, I don't think your last paragraph on the subject in that place is limited enough. There is such a thing as giving even the beginner too little strong meat.

What is wanted now is to construct in the minds of bee-keepers an up-to-date map of the United States, in which small-hive and large-hive localities shall emerge in splotches of very strongly contrasting colors. I don't think that "latitude" has any thing to do with it, as is sometimes stated. If alfalfa were extensively raised in Idaho and Montana, it is not probable they would be different from Colorado in suitability for large hives, unless cellar wintering were essential, which is not likely. Nor has temperature so much to do with it as is commonly supposed. The alfalfa region of Colorado has the same average yearly temperature as Southern Michigan and Northern Iowa, although, of course, other climatic conditions are different.

Small hives do well almost anywhere, it is true; but if large hives do considerably better over such large areas as the alfalfa districts, it is a serious matter, not to mention various regions in the South. Very little testimony has appeared in the bee-papers from Colorado; but in conventions, experienced bee-keepers have decided here in no uncertain tones that the large hive is better for this State.

Out of 3200 Dovetailed hives sold last season by one of the Denver supply-houses, the majority were eight-frame. In another supply-house I saw great stacks of eight-frame hives, but not a ten-frame in sight, though I suppose they had them. I noticed one beginner laying in a smoker, sections, etc., and five hives—small ones, of course. This is not as it should be. Who is to blame for it? Partly the supply-dealers, who are not bee-keepers, who infer that whatever is generally sold in the East must be the thing; partly habits of imitation; and in the case of readers of bee-journals and supply-catalogs, and partly the authors of the

sentiment so frequently expressed, that the beginner had better commence with the small hive. The beginning specialist will not remain a beginner, however. If he is in a locality where the experience of others makes it pretty certain that his maturer judgment will show advice of that kind to be a mistake, the folly of taking it or giving it is apparent.

I rather suspect that the owners of those eight-frame L. hives mentioned on page 738 in that locality of long flow are like most of our Colorado bee-keepers—beginners—and that they too depend on supply-dealers who look to the wise men of the East for their inspiration.

Mr. Hand is not quite fair on page 512. If some Colorado men grow restive under the above condition of things, it does not imply that they wish to force the large hive on all the rest of the country. Surely, if Mr. Hand feels justified in protesting against what he thinks we are attempting to do, we are justified in protesting against what we know some Easterners are doing; viz., recommending the hive of their locality to beginners in any locality.

ALFALFA; HOW IT RESEMBLES SWEET CLOVER.

Dr. Miller's Straw on alfalfa (p. 727) is about right if he is comparing alfalfa with *young* sweet clover. The only difference at that stage is, that sweet clover is of a lighter shade of green; has slightly larger leaves and stems, and a more robust appearance generally. But the mature plants are very different. Sweet clover is then twice as high, branches out much more, has a much greater prominence of stems, and is considerably longer, thinner, and has more pointed blossoms, than alfalfa. Aside from the blossoms, and except when it gets quite old, alfalfa presents the general appearance of young sweet clover.

Dr. Miller might add to another Straw on the next page, that alfalfa is mentioned in some of the Greek authors as "Persian grass." Perhaps Persia is where it originally came from. It is rather curious that Aristotle says it diminishes the flow of milk, which is just the opposite of what our dairymen think, who prize it for its milk-producing qualities when it is cut before it blossoms (alas for the bee-keeper!). Aristophanes mentions it as horse-feed, but it is not regarded here as so good for that purpose as other kinds of hay. When used to feed horses it is better when fully mature; and the first crop is better than succeeding ones, the reverse being true for cows. It is raised here so extensively only as a matter of necessity, on account of its drouth-resisting qualities. On account of its abundance it is so cheap that clover would pay better if one were sure of the second crop.

THE HONEY THAT POISONED XENOPHON'S SOLDIERS IN ANCIENT TIMES.

Speaking of classical matters, I believe, Prof. Cook denies that the honey which Xenophon's army ate was poisonous, and thinks any honey

would ausce the same effects in those not accustomed to it. This is of some interest to us, on account of the alleged poisonous qualities of yellow-jessamine and mountain-laurel honey in the South. If honey from one plant is proved to be poisonous, it is not impossible that honey from another plant could be. I have been looking the matter up, and don't see how he reaches his conclusions. Not to speak of the testimony of several modern travelers, given with some detail in Vollbrecht's *Anabasis*, Xenophon's own words are rather unmistakable. Besides the sickening effects, which any honey might produce, those who had eaten a little seemed to be heavily intoxicated; and those who had eaten much lost their senses and did not regain them until twenty-four hours after, "recovering on the third or fourth day as if from the effects of a drug." One does not become delirious from indigestion merely. The honey now produced in that region is known by a term signifying "mad honey."

Arvada, Col., Oct. 9.

[I wrote the paragraph in the catalog, recommending the eight-frame hive, to which you refer, and at that time that size of hive seemed to be accepted as the nearest right for the average bee-keeper, and for the average locality; but now it looks as if it would not be safe to make any recommendation; and we have therefore decided that, for another year, we will request bee-keepers to state what size of hive they desire. Of course, we shall send out the smallest, or eight-frame, size, when no size is specified. I am quite well satisfied, however, that, in regions where there are long honey-flows, and the flows are copious, too, that the large hives are best. I am satisfied that the eight-frame size has given remarkable results in the East; but I am not so satisfied that the results would not have been better had the ten-frame size been used instead.

It would indeed be a good idea to get out a map showing where the regions where ten-frames, or hives with that capacity, were the most used; where the eight frame has the preference; where the two sizes seem to be mixed up indiscriminately according to the fancy and taste of the bee-keeper; and I propose, if it is possible, to have one made. But to do so I shall need reports from bee-keepers all over the country, who will voluntarily let me know, on a postal, what kinds of hives are used. But they must be sure to specify what part of the State they live in.

After the map is prepared we will have it photo-engraved, and submitted to our readers, after which, revised and re-revised, if necessary, to make it correspond with existing conditions. This will settle the hive question in a more practical way than any other I know of, and will, perhaps, be a fit ending to the discussion that has been long drawn out.—Ed.]

WHAT IS A LARGE COLONY?

By J. E. Hand.

Mr. Root:—I notice on page 733 that Dr. Miller calls me up to explain what constitutes too large a colony. Why, too many bees, of course, doctor. Perhaps you will understand better

what that means after you get your queens to fill those two eight-frame brood-chambers with eggs, but yours will be too large just after the close of the honey-harvest.

The next question, why too large a colony in early spring does not do as well at harvest time as one that arrives at the proper strength for work in the sections at the beginning of harvest, is a little harder to answer; but such has been my experience. Many times I have watched with great expectations an extra-large colony in early spring, which just fairly roared with bees long before the others had made much of a show, and perhaps swarmed two or three weeks before the white-clover harvest; and in every instance I have been disappointed by seeing such colonies far outstripped in honey-storing by average colonies that arrived at the proper strength for work at the right time. I can see that location might make a great difference in this matter, as it does in almost every thing connected with the business. In my location bees were very often destitute of honey at the beginning of the white-clover harvest.

I distinctly remember the best season I ever experienced, when I had to feed my bees the 10th of June to keep them from uncapping their brood, and in two or three days they commenced work on white clover, and averaged 110 lbs. per colony.

I have had some experience with queens laying in upper stories when working for extracted honey, and they became such a nuisance that I was obliged to use queen-excluders on all such hives, or have the combs that should be filled with honey crammed with brood that cost a great many pounds of honey to produce, and which would not hatch in time to gather an ounce of honey; and at the close of the season the bees would nearly always be in the upper story, with the lower one entirely empty.

If I were going to use two eight-frame brood-chambers I should want a queen in each with a double queen-excluder between, and, at the beginning of the harvest, remove one to a new stand, and place the surplus-receptacles on the hive which remains on the old stand. This would suit my location much better.

Wakeman, O., Oct. 14.

SIZE OF HIVES.

THE STANDARD LANGSTROTH NEAREST RIGHT SIZE; WEIGHT OF HIVE NOT TO BE CONSIDERED.

By J. S. Hartzell.

It has not been made clear as to what is the better hive for the general bee-keeper. Very many want a hive similar to the cluster of a swarm. Is it not a fact that a swarm adapts itself to the cavity or receptacle, in which placed, be it of what shape it may? Now, bee-keeping friends, with all due respect for all who

have written and may write on the subject of hives (and I only hope more may be said), don't you think that father Langstroth, in adopting a size of frame, and ten frames per hive, came as near filling the wants of the general bee-keeper as it is likely or possible to do?

I notice that many find fault with the weight of the larger hives when filled; but now the season of 1895 is closed, how about stores? I presume many—yes, very many—of the bee-keepers are only wishing for weight; and if they had heavy and abundant stores, no complaint as to weight would be heard. I can truthfully say that I should prefer hiring help to handle hives heavily stored than to be able to handle the lighter weights lone-handed.

Addison, Pa., Sept. 20.

[Is it not indeed remarkable—yes, very remarkable—that Mr. Langstroth, without the aid of previous literature to guide him, should, almost alone, be able to settle these problems so nearly right every time? The mere fact that the ten-frame hive is coming to be recognized after all, as the standard; that the Langstroth hive *as a whole* has been a standard all these years—is a proof of how far-seeing Mr. Langstroth was in his early years. For example, again, bee-spaces, about which we hear so much nowadays, were first provided for in the construction of the hive by Langstroth. Thick and wide top-bars will be found in old hives after Langstroth away back in the early sixties. Honey-boards, with a provision for a bee-space on both sides, were a part of the Langstroth system. Verily, he seems to have marked out a pathway for the whole of us.—ED.]

QUEENS WORKING IN ADDED STORY.

NOT "SHARP STICKS" BUT CLUBS FOR DR. MILLER; THE EXTRA-LIFTING QUESTION, ETC.

By C. A. Hatch.

I had thought that I had said all there was for me to say on the 8 and 10 frame question; but Dr. Miller has aimed a club straight at me, and if I do not "cheep" he will think he has hit me hard or downed me entirely; and to have him think that would be too humiliating. But here, after judging from Oct. 1st GLEANINGS, all there is for the ten-framers to do to give Dr. M. good hard knocks on the hive question is to turn one of his own household against him. Go for him, Miss Emma; you will fetch him yet. He will find out, before he is 40 years older, that a queen will not climb up and down over an inch of wood and half an inch of space to lay eggs on both sides of it, as readily as she will step from one comb to another. And hit him again on the lifting-off of that top hive every time he has to examine the colony, and perhaps he will see that the extra work is all on the side of the small hive; and may be you will convince yourself that all this extra work during the honey season will compensate for the heaviness of the hive in moving time.

But, to answer Dr. M.'s question, "What kind of frames did you use when the queen would not go back and forth from top to bottom hive?" The common three-cornered top-bar, $\frac{3}{8}$ inch each way, bottom-bar $\frac{1}{2} \times \frac{3}{4}$ inch, with about $\frac{1}{2}$ inch space between them when tiered up, with but few burr-combs. It is plain that the reason your queen went back and forth so readily was that the space between, being filled with comb, it was to all intents and purposes one comb.

In the case of those obstinate bees and *very* obstinate queens that refused to lay in the top at all, are you sure the queen was at fault? To me it only shows the good hard sense of the bees themselves in refusing to fix up the combs for eggs when nature said, "There is the place for the surplus honey." Did you examine the combs to see if the bees had fixed them ready for eggs? Were they cut down to the right length, and cleaned and polished? If not, how do you know but you were killing that poor innocent queen for something she was entirely guiltless of? for you must have observed that, unless a queen has a cell all clean and polished to her liking, she will not put an egg in it. And to make sure that this is so, she examines each and every cell before depositing her egg in it.

As to that extra lifting, Dr. M., that is keeping you out of the camp of the ten-framers, there is only one time that the two extra frames make much difference, and that is when carrying into the cellar. Come right over, doctor; we will welcome you with open arms, and you will find that the ten-framers' hearts are large, like their hives. If those eight-frame hives you have on hand stand in the way, put some lath across the bottom, and use them for boxes to store vegetables in. Your assistant, Miss Wilson, has put the case quite strong indeed, and shows she is really a convert, but holds back a little for consistency's sake. Even the Roots have had to acknowledge some things they would not at the start, and we *may* convert them yet.

If all men had the candor and honesty of B. Taylor, to acknowledge a hive a failure after making it a hobby for years, we might sooner get at the truth of things; but I am afraid we are all more or less warped by our prejudices.

That idea of yours, Dr. M., to have combs filled in the fall, ready for the bee-feeding in spring, is a good one; but let the bees put it right in their own hives, and then you have got it all "solid," and no trouble about getting them to take honey from a feeder in the spring either—another argument for two more frames in the hive—see?

Send on your clubs, doctor; we will throw them back, any way.

Ithaca, Wis., Oct. 8.

[Friend Hatch was the man who started this large and small hive discussion a little over a

year ago. At that time the most of us thought he might as well keep still, as every one would be "agin him" in experience. And, indeed, we tried to club him down; but so many ten-frame users came to his rescue, and more are coming, that it looks quite probable that the single-story eight-frame capacity for brood for many localities is too small to get the best results in honey. Indeed, it begins to appear pretty forcibly that the majority of extensive bee-keepers are in favor of a brood-nest of a capacity larger than the eight-frame Langstroth of single story for nearly all localities. But here is the situation here at Medina: Is not even the ten-frame too small? and would it not be better to have two eight-frame stories, one above the other, as one brood-nest? O. O. Poppleton, who leads off the discussion in this issue, and he is one whose opinions we value much, would have 16 frames. We get brood in both our stories easy enough, and it seems others do, although our friend who won't be clubbed down does not.—Ed.]

JAKE SMITH'S LETTER.

Mr. A. Gleanings, Dear Sir:—Zed reads a good eel in your paper. One day he had been a readin, and he speaks up and says he, "I believe that man has the right of it. Here's a man on page 164 who says a big hive is warmer than a little one. Now a body wouldn't think that till he comes to explain it."

"Zed," says I, "it's pretty hard to explain how it's easier to keep a big room warm than a little one."

"Well, it's easy enough after you hear how he explains it," says Zed. Then he read from page 164 of your paper: "I believe the bees form what is known as an inside hive. By this is meant that, around the margins of brood, the bees arrange themselves in such solid lines between the combs as to prevent a circulation of air from within or without the cluster, for the purpose of keeping a high temperature there while they allow the rest of the hive to arrange its own temperature; consequently, in cold weather the walls are often coated with frost; and in southern California, where frosts seldom come, we find the walls and unoccupied combs dripping with moisture. From this it would seem that the ten-frame hive is actually warmer than the eight, as the cluster of bees and brood would be able to locate farther from the outside walls. Even if the cluster was warm enough and near enough to the walls to dispel the moisture or frost, it would require warmth to do it, and such warmth would disappear in the operation, and could not aid in brood-rearing, as where there is no frost to be dispelled." Then he read in other places: "The more frames in the outside hive, the longer beam would there be re-

quired between the outside and inside cellar walls. . . . The more dead air, the more protection." "Now," says Zed, "don't you understand how it is?"

"That's too high-larnt for me," says I; "I don't understand a word of it; but it seems to me it had ought to take more to keep a big room warm than a little one."

A few days afterward Jim Short come around, and Zed brought up about a big hive bein warmer than a little one, and read all about it in your paper. Jim said he didn't know about it."

"Why, can't you see," says Zed, "that when the bees are jam up again a wall it takes heat from them to warm that wall; but dead air will keep them warm; and 'the more dead air the more protection?'"

"You think, then," says Jim, "that it's warmer if the bees are four inches from the wall than if they're only two."

"Now you've got the idee," says Zed.

"And 8 inches would be still better than 4."

"Certain," says Zed.

"And 16 better still."

"Ye——I suppose so," says Zed.

"And if it was ten foot to the walls all around," says Jim, "then I s'pose it would git so hot the bees could hardly stay in the hive in winter."

Zed didn't say a word—jest looked.

"Zed," says Jim, "I'm afeered there's a screw loose somewhere."

By that time I begun to study over it, and, says I, "I s'pose the bees know pirty well what's warm and what's cold. When it gits too hot in a hive they git out where it's cooler; and when it freezes they huddle up together to keep warm. Now don't you s'pose the bees

would hunt out the warmest place in the hive when you hive them?"

Zed said of course they would.

"And do they always cluster right in the middle of the hive as far from the walls as they can git?"

Zed allowed they didn't.

"No," says I, "when you hive a swarm in an empty hive, the first thing it does is to cluster up as tight as it can git, right up again the walls."

"Yes," says Zed, "of course they do; but that's because it's hot weather, and they want to git where it's as cool as they can."

Then you ought to heard Jim laugh. "Zed's got the start of you," says he.

"Do you mind," says I, "that little swarm we hived under the pear-tree, and it turned nearly freezin' that night? How was it when we turned up the hive to look at it the next mornin'?"

Zed's pirty fair on an argument; I'll say that, if he is my boy; and he owned up right straight that the swarm was shrunk up to almost nothing in one corner of the hive.

Just then a knock came at the door, and a wild-eyed female individual entered with a handbill in her hand which she held aloft, and, says she, in exsighted axcents, "Is Rambler here? I'm his slighted Eugenia!" □

Then she shook the handbill, and, says she, "That's what comes of havin' foreign women so plenty. He deserted his dear Eugenia because he wanted a woman of royal blood! Nothing but a queen would do him! And to think that it's come to that, that one of them would offer herself for three dollars!"

Jim whispered to me, and, says he, "She's off in her upper story."

"May be she is," says I; "but Rambler has much to answer for."

JAKE SMITH.

variable temperature it will not be as good for the bees as would one in which the temperature could be kept as nearly at 45° as possible; yet if the temperature does not go above 50°, nor go lower than 35, it will winter bees much better than to leave them on the summer stand unprotected. If the cellar is of more variable temperature than this, the bees would be doubtless better off out of doors. To properly fix the hives for wintering in the cellar they should be carefully carried in on some morning when it is a little cooler outside than the temperature which is required for the bees to fly, and never when the hives are frozen down to the bottom-boards or to the ground, if this can possibly be helped. When the hives are thus frozen down, the jar and confusion which comes from prying them loose results in great irritation to the bees, and causes them to consume so much honey that it often leads to unsuccessful wintering afterward. After getting them to the cellar the hives should be set on a bench a foot or more off the cellar bottom, and the hives raised by some means at least two inches off the bottom-board or bench. Failing to do this the hives will not be properly ventilated, and the result will be that the bees may become uneasy from lack of proper ventilation, which will cause them to consume more stores than is necessary to their existence, thereby needlessly using up the honey, and often leading to disease and death. If it is not convenient to thus place them, the hives may be turned bottom side up if the frames are fast or box hives are used, and a light thin fabric of some cotton goods thrown over the hive; still, the first is much to be preferred. I also believe that the cellar should be dark, or that part of it in which the bees are wintered. Some claim that bees will winter as well in a light cellar as in a dark one, which may possibly be so if all of the conditions for successful wintering are present; but as such conditions are usually not all present in many (if any) cellars, it is always best to be on the safe side; hence the advice to have the cellar dark.

If the cellar is lacking in many of the qualities which go to make a good cellar for wintering bees, then it may be best not to try it at all, in which case we must try the next best plan, and one which is quite well suited to all latitudes south of 44°—that is, wintering on the summer stand packed with chaff, fine hay, or straw. While a chaff hive is the preferable thing, yet it is not supposable that all may have such hives, so we must fix the bees the best we can according to our environments. If you do not have chaff hives, go to the store and procure dry-goods boxes of a suitable size, or otherwise make them, in which the hives can be set, and leave room all around for the packing. A space of about four inches is the right amount to leave, for experience has proven

WHERE SHALL WE WINTER BEES?

Question.—I have several colonies of bees for the first time in my life, and wish to know where and how it will be best to winter them. Shall I put them in a cellar, wrap them up, or let them be as they are for winter?

Answer.—There is probably no better place to winter bees than in a good dry cellar; and if the questioner has such a cellar I would advise him to set his bees in it for wintering. While this is not absolutely necessary for safe wintering, and not as necessary in our southern as in our more northern localities, yet there will be a great saving of honey to the apiarist, as well as better chances of successful wintering, even as far south as all but the most southern tier of States. If the cellar of the questioner has a

that this is better than a larger or smaller amount. The bottom-board should be raised that distance above the bottom of the box, and, after having packed under it, it should be secured there, and so as to touch the front side of the box also, as the bees must pass over this to get outside of the box. Half an inch above the bottom-board a thinner board should be secured in the same way to both the hive and box, immediately above the entrance to the hive, so as to keep the packing-material from obstructing the passage of the bees, for this is now to become the entrance to the hive.

Having this fixed, and the hive thoroughly secured to its place, we now put in the packing, pressing it in tightly, so that as even a temperature as possible can be maintained inside of the hive, packing the material in as nearly alike on all sides as possible. When the top of the hive is reached, the honey-board, if one is used, should be removed, and two or three thicknesses of cotton cloth spread over the top to keep the packing from rattling down into the hive, and also that, in thus providing for ventilation, a direct draft shall not be allowed through the hive.

Having all fixed as above, fill in the packing to the depth of four inches all over the top of the other packing, as well as over the hive, keeping it as evenly distributed as possible, but allowing it to be more loose and open than at the sides. The box should be tall enough so as to come a few inches above the packing, so that the cover, which is now to be put on, shall not touch it. This last is very important; for where the packing touches the cover to the box it will absorb the moisture which condenses on the cover, to such an extent that all will become wet and moldy long before spring.

No matter whether it is chaff hives or boxes packed as above, there should always be a few inches space above the chaff or packing, so that the moisture arising from the bees may have a chance to pass off to the outside air with as little condensation as possible. Having your bees thus fixed, or in a good cellar, they will winter much better than if left to take their chances in unprotected hives.

LYSOL A SUCCESS AS A CURE FOR FOUL BROOD.

Report from here is poor. Basswood did great for ten days, but no honey since—not enough to keep up brood-rearing. Well, we have no foul brood now. One colony has some dead brood, killed by feeding lysol. I used a hive that had foul brood last season, and fed two feeds too close together, so that the young

larvæ got two doses, and that will fix them sure. Lysol will cure foul brood here in Michigan. I have treated 7 colonies for another party, and they are now all healthy; but it may return next season. More lysol will do the business, so will McEvoy's way of doing. Can't scare me out of another year's growth with it again.

Northville, Mich.

CHAS. BIERY.

[We are very glad to get this report of the effectiveness of lysol as a cure for foul brood. It will be remembered that, after friend Cravenhorst, editor of the *Bienenzeitung* (Germany), suggested to us this new remedy, we procured some of the drug and sent samples of it out for the cost of postage, to those who would try it. As we sent out at the time quite a number of samples, I should like to hear from those who obtained it as to how it worked.—Ed.]

ANOTHER REASON WHY THE HIVE DISCUSSION SHOULD BE CONTINUED.

By all means keep up the hive discussion. It may help other bee-keepers, as it has me, to find just where I am "at" on the hive question. I will try to write you shortly in reference to the standard cubical hive.

Mentone, Ala., Oct. 15.

C. F. PARKER.

MEMORIAL.

While the Southwestern Wisconsin Bee-keepers' Association was in session, Oct. 8, in Platteville, the sad news of the death of Rev. L. L. Langstroth was received. Therefore be it resolved:

That this society deplores the loss of father Langstroth, who died at his post of duty while preaching gospel truths.

That his life has ever been an example of study, thought, and deed.

That by his invention of the most practical movable-frame hive, 1851, and his book, 1852, "The Hive and Honey-bee," Mr. Langstroth laid the foundation of American apiculture.

That a copy of these resolutions be published in *American Bee Journal* and *GLEANINGS IN BEE CULTURE*.

N. FRANCE, Pres.

M. M. RICE, Sec'y.

VALUE OF BEES AS FERTILIZERS, AGAIN.

I would call your attention to the inclosed clip from the *Experiment Station Record*, Vol. VII., No. 1, 1895.

A. T. GOLDSBOROUGH.

Washington, D. C.

[The following is the item referred to, and simply corroborates a mountain of other evidence to the same effect:]

FRUITS. G. COOTE (*Oregon Sta. Bul.* 34, pp. 19-29, pls. 2).—This bulletin comprises notes on various varieties of orchard and small fruits grown at the station, with some general remarks on pollination and fertilization of flowers by bees and otherwise. Tabulated comparative notes are given of the date of blooming and pollen-production for 21 varieties of cherries, 28 of plums, 11 of peaches, 14 of pears, and 22 of apples, the relative abundance of pollen being also designated.

Experiments were made with peach-trees in a forcing-house to determine their power of self-fertilization. Fertilization was done by hand, a brush being used, by spraying with water when the trees

were in full bloom, and by placing a hive of bees in the house. All the fruit was matured on the tree to which the bees were allowed access, while more or less dropped at the stoning period in the case of the trees fertilized by artificial means. A tree protected from the bees, and not otherwise fertilized, set no fruit whatever.

WHAT TO DO WITH HONEY SOURED IN THE COMB.

What would you do with brood-frames filled with sour honey? It soured in the cellar last winter, and the bees died. I have a solar wax-extractor; could I extract it as it is?

Rice Lake, Wis.

LYDIA AMERMAN.

[I would put the honey, comb and all, in the solar wax-extractor. The wax, when melted, will rise to the top, when the honey can be drawn off. If it is not then sweetened by the heat, throw it away or use it for vinegar. If the combs are good and worth saving, extract the honey and heat it over the stove.—Ed.]

A CORRECTION AS TO THE AMOUNT OF HONEY SENT TO THE COLONIAL EXHIBITION IN 1886.

It is to be regretted that it is so difficult to catch up with and down an untruth, once it "gets a going." There is no doubt that Mr. W. S. Hughes, the writer of that biographical sketch of Mr. M. B. Holmes, intended to give correct figures when he said, "Ontario sent about 40 tons of honey to the Colonial and Indian Exhibition in 1886;" but, in fact, we sent only about 20 Canadian tons; but that would not make 20 British tons, by any means, which makes the untruth all the more to be regretted.

I very well remember the nice large exhibit of honey sent to that exhibition by our enterprising brother Holmes. It gives me pleasure even to this day to go over in my mind the noble manner in which Bros. Holmes and J. K. Darling, living as they do away off in the east end of the province, responded to the call for honey to send to that exhibition. All their correspondence was prompt, courteous, and business-like, and their promises carefully kept. It is a pleasure to do business with such men.

Belmont, Ont., Oct. 21.

S. T. PETTIT.

STICKY FLY-PAPER IN THE TREATMENT OF FOUL BROOD; HOW EASILY RECOGNIZED FROM THE DESCRIPTION GIVEN IN THE A B C OF BEE CULTURE.

I have been working in foul brood, and I went to the A B C for treatment. I had eight colonies badly affected, and I think the disease well named. I would say to those who have never had it, you need not guess at whether you have it or not. You can tell as soon as you see or smell it, to a certainty, from the description in the A B C. I used to think every bit of chilled brood I saw was foul brood sure, and was always looking for it as if it took fine work to detect its presence. I thought I could smell it for a week after I got it burnt. I took the best to try my hand at curing; the others, I burned (kept the hives and immersed in boiling water, as directed in the A B C).

As there is some doubt expressed in the book as to our being able to get all the bees, I will tell you how we did. We brimstoned them after night, and let the hive stay on the stand over the next day. Having the entrance corked tightly, we took a sheet of tanglefoot fly-paper and cut a hole in it over the corked entrance. This caught every straggler. After scalding the hives I painted them inside with 5 per cent dilute carbolic acid.

I started up with 5 Hoffman frames to the hive; and after the bees were put in on the foundation I let them stay confined 48 hours, then fed, and let out next day after feeding at sundown. We boiled the honey to feed them inside at night. They seem to be coming up, as the A B C says, with June prosperity, notwithstanding the comment that it doesn't work with some. I neglected to say that we used fly-paper at the entrances of those confined, and think it works finely to catch the stragglers anywhere.

Will you kindly tell me whether it would be best to burn the sections drawn out on those hives this year? I do not want to take any chances that I might avoid, of its return.

Saltsburg, Pa.

G. W. MARTIN.

[The use of sticky fly-paper is a new and excellent suggestion. If we should be so unfortunate as to have at some future time another case we shall try it. The five-per-cent dilution is not strong enough to do any good. Better boil the hives thoroughly. The sections you refer to had best be burned.—Ed.]

THE GIANT BAMBOO.

[The following verses were sent us by friend A. F. Brown, of San Mateo, Fla. He says he came across them about the time he read A. I. R.'s description of the bamboo. We do not know where they originated.—Ed.]

One night when the hills were drenched with dew,
And moonbeams lay about,
The comical cone of a young bamboo
Came cautiously creeping out.

It tossed its cup upon the ground,
Amazed at the sudden light;
And so pleased was it with the world it found
That it grew six feet that night.

It grew and it grew in the summer breeze;
It grew and it grew, until
It looked right over the camphor-trees
To the further side of the hill.

A Japanese phrase the wood-cutter used
"Fine tree!" is what we should say,
He chopped it all round, till it fell to the ground;
His oxen then hauled it away.

He made a fine tub from the lowermost round,
A pail from the following one;
A caddy for rice from the very next slice,
And his work was no more than begun.

The next were tall vases and medicine-cases,
With dippers and drink cups galore;
There were platters and bowls, and pickets and poles,
And matting to spread on the floor.

A parasol-frame and an intricate game,
And the ribs to a paper fan;
A sole to his shoe, and a toothpick or two,
He next made—this wonderful man.

A pencil, I think, and a bottle for ink,
And a stem for his miniat'ire pipe;
A ring for his hand, and a luncheon stand,
And a tray for the oranges ripe.

A rake then he made, and a small garden spade,
And a trellis to loop up his vine;
A flute which he blew, a tea-strainer too,
And a fiddle to squeak shrill and fine.

It would take me all day, if I were to say
All that wonderful man brought to view;
But a traveler I met says he's sitting there yet,
At work on that single bamboo.

Yes, the bee sings—I confess it—
Sweet as honey—heaven bless it—
Yet he'd be a sweeter singer,
Ef he didn't have no stinger.

RILEY.

A MORE full and complete description of A. I. R.'s visit to Battle Creek will be given in our next issue.

In our next issue, as explained in another column, the symposium on "Wintering" will be made up of articles from the following-named bee-keepers, so far as we have yet heard from them: H. R. Boardman, C. A. Hatch, J. E. Crane, B. Taylor, Friedman Greiner, S. T. Pettit. A number of others will also contribute, but I can not announce their names until I hear from them.

I REGRET that we have not room for all the Reports Encouraging and Discouraging, or even any of them, in fact, for a few numbers to come. Those that came during the month of August and the fore part of September were about equally divided between the two classes; but lately there seem many more of the encouraging sort. These report good fall flows which, in the majority of cases, means no feeding of sugar. Orders for shipping-cases have been coming at a good rate. "There has been a good run of buckwheat honey in the East; but there was not much to speak of from goldenrod.

In February, 1885, there was held an international bee-keepers' congress in New Orleans, on the exposition grounds. That was one of the largest and most enthusiastic gatherings of bee-keepers I ever attended, and I know of no meeting of the North American that was larger numerically than that, except the one held at Chicago during the World's Fair. Well, there is to be another bee-keepers' congress, this time at the Atlanta exposition, Dec. 4 and 5. I am informed that "present indications show that it is going to be a large representative gathering of bee-keepers from all parts of the Union." Dr. J. P. H. Brown, of Augusta, Ga., is the prime mover in the matter, and he, doubtless, will supply us with information later, giving us program and further particulars. This congress is in no way connected, as I understand, with the North American or any other association. It is simply an informal gathering of bee-keepers, the same as was witnessed at New Orleans.

COMPOUND NUMBERS FOR HIVES.

E. E. HASTY, in the *Review*, referring to the discussion on the subject of numbering hives,

thinks "a hive needs a *visible* number on it no more than a toad needs a tail, if a strict arrangement by groups is followed." He uses a compound number. The first figure indicates the group and the second the position in the group; thus, 16-9 would mean the ninth hive in the sixteenth group. I have no doubt that friend H. can carry out this plan for himself without the "visible number." But suppose he hired help, and he should direct his man, not very familiar with the arrangement, to 16-9. In the first place he would not know from which end to commence numbering; and, even if he did know, he would have to count up till he got to 16, and then count again. The plan of compound numbers is tiptop, as it helps to locate the hive; but when the expense is merely nominal I would have the visible number by all means.

In this connection I may remark that H. R. Boardman, of East Townsend, O., letters the rows and numbers the hives. For instance, tag B-3 on the hive means second row and third hive. Where hives are carried into a repository, and it is desirable to put them back in the same place in the spring, this arrangement or the compound number of Hasty's is certainly convenient.

FUTURE SYMPOSIUMS FOR GLEANINGS.

It is getting to be quite the fashion to introduce, now and then, symposiums—a number of articles on one subject—in class and especially in trade journals. This was once a prominent and admirable feature in the *Review*; but lately it seems to have been discontinued. In inaugurating something similar in our columns, and with no thought of copying after our excellent cotemporary, my idea has been not so much to focus the opinions of our best writers in one issue as to gather together ideas from bright practical men who write only occasionally. These ideas are to serve as food for thought for future issues, and for a better comparison of notes. Such has been somewhat the character of the hive discussion—pollenization of flowers by bees; crimson clover; fixed distances, and others that I will not stop to name. Single-issue symposiums are good so far as they go; but it is seldom that one set of writers in one number can come anywhere near solving a problem, or of giving us *all* the light that can be thrown upon the question. As time goes on, old accepted opinions become obsolete. It has seemed to me that the "Wintering Question," once an old chestnut, should be at least looked over; and the best light we have should be thrown upon it; i. e., to use a little modern parlance that expresses the idea better than any thing else, "see where we are at." "What! that stale old subject?" you ask. Yes, but I plan to have it so presented that it shall be fresh.

I have asked a number of our prominent and

successful bee-men to give briefly their present method of wintering, and then in the same article what they have learned in the last three or four years that has been helpful along this line. My idea is, to learn how nearly the successful ones follow the same or essentially the same methods. If these methods are generally the same it will be proof that they are nearly the correct ones; and then I am sure that the last few years have thrown light on problems that a few years ago were totally unsolved. The question will then be open for others to discuss for one or two numbers.

In our issue for Dec. 1st, or perhaps the one for the 15th, I am planning a symposium on Langstroth; his early career; his inventions, and their relative value; in short, his place in the history of bee-keeping which he, more than any other man in the world, raised to its present standard. A. I. R. and I both feel that the father of American bee-keeping has never been fully appreciated, even by the bee-men of this country. Now that he has but so recently passed from our midst, it is but fitting that a worthy tribute should be extended to his memory. I have already called upon some of the foremost bee-keepers of our land for articles calling attention to some of the features in Mr. L.'s career above pointed out; and, in addition, there will be other papers giving some interesting reminiscences showing the many-sidedness of that man whom, I know, we are all delighted to honor. These, of course, will be supplementary to the article by A. I. R., in last issue.

We shall be printing an extra-large number of copies of the journal for both these issues—even larger than what we are now putting out from the press—12,000 copies. Advertisers should not fail to make a note of this.

Later announcements will be given regarding the symposium above mentioned; and, as the year grows on, other special features that will be prominent for the year to come. Now, dear reader, even if times are hard, and even if the bees didn't pay extremely well, can you afford not to remain with us?

HOW TO MAKE SUGAR SYRUP WITHOUT HEAT OR PERCOLATION.

LAST fall I had much to say about percolating syrup by the cold process of feeding sugar and water, half and half, in percolator feeders. It will be remembered that I was very enthusiastic over the plan; for, indeed, it was a great saving in time and bother over the old way of mixing and stirring over the hot stove, to say nothing of the liability to scorch the whole batch and the mussing of wash-boilers, stoves, and utensils in general.

This year, when we began our feeding operations we practiced the percolating plan; but very shortly we discovered an improvement, and I reported the same on page 745, Oct. 1st

issue. At that time I expressed a hope that we might be able to get along without the percolation, and I then referred to the plan practiced by F. A. Salisbury—that of mixing sugar and water, in equal proportions, in an ordinary honey-extractor, and revolving the reel until all the sugar is taken up. From some preliminary tests that I had made I did not think favorably of the plan, and so reported last fall. But more of this anon.

As we did not have enough percolator feeders to go around, our Mr. Spafford, of the apiary, tried mixing, in an ordinary can or barrel, sugar and cold water, giving it an occasional stirring with a stick during the day. If he mixed the sugar and water, and stirred it well, say the first thing in the morning, and stirred it again at noon, and again at night, before leaving, he found the next morning, to his satisfaction, clear and limpid syrup of a consistency of 32 by the ordinary maple-syrup hygrometers. He made several barrels of sugar into syrup by this plan, and in every case the syrup was of first quality, as good as that made by artificial heat, away over to the factory. This I regarded as not only a good hit but a great saving in time, because the food could be prepared in the honey-house, right in the apiary; and then, too, this "made syrup" could be fed in the Miller feeders. These, for late feeding, are ahead of any thing else we know of.

I forgot to say that, later on, instead of making the proportions equal parts, he used three measures of sugar and two of water, and succeeded in getting clear syrup without granules, as when he used equal parts.

THE SALISBURY COLD PROCESS; HOW TO MAKE SUGAR SYRUP, A WHOLE BARRELFUL IN TEN MINUTES.

When Mr. Salisbury, of Syracuse, made us a visit a short time ago I told him of our plan of making syrup, that we were using with success. "But my plan," said he, "is shorter and better yet. It takes only ten minutes to make a big batch."

"But why couldn't I do it then? I tried it, and it didn't work very satisfactorily."

"Well, then you didn't try it right," he insisted. "You let me take one of your extractors to-morrow morning, and I think I can show you how to make the syrup—a whole canful—in ten minutes."

"All right," said I, "thinking that I could show him that he couldn't."

Next morning he and Mr. Spafford made one batch, taking sugar and water half and half, in ten minutes; and shortly after, another batch, one-third water and two-thirds sugar, in fifteen minutes; but, as he afterward told me, he turned the reel "good and hard." I was to witness the operation, but something called me away, and the boys didn't wait.

After dinner I went out to the apiary with

Mr. Salisbury, to look at the samples in glass jars that were placed outside in the bright light of the sun so that any undissolved granules could be seen. Sure enough, the half-and-half mixture was as clear as crystal.

"But the other jar looks cloudy," I said.

"The half-and-half jar," he explained, "looked the same way, but, as you see, is now clear. The cloudy appearance is due, not to undissolved particles of sugar, but to air-bubbles. You see, the cloudiness is more dense at the top, showing that the air-bubbles are rising. If they were granules they would be settling, and the clearing would be at the top first, instead of at the bottom.

Even while we stood there it was plainly evident that friend S. was right; for the thicker syrup was also clearing up rapidly, and, shortly after, it was indeed as clear as the other jar.

"That explains," I said, "why I condemned the plan as a failure. I saw that peculiar cloudiness of the syrup after the stirring, and concluded that the sugar was not all dissolved, when in fact it probably was; but tell me," I continued, "just how you made the syrup in ten minutes."

"In the first place we fill the extractor half full of water; and then as we revolve the reel we put in the sugar by the pailful until the can is filled, or nearly so. The object of putting in the sugar *after* the water, is in order to get the granules thoroughly dissolved while the extractor-basket is revolving. If the *sugar* is put in first it will make a sodden mass when the water is added, and require much more stirring."

"You prefer to make the syrup thin—half and half," I said.

"Yes, because I feed early, and then I am sure the bees can thicken it far better than we can."

"But," said I, "we often have to feed late, owing to the uniting of nuclei after the queens are sold in the fall."

"The syrup can be made thicker for late feeding, as we demonstrated this morning, only it may take a little longer."

IS SYRUP MADE BY THE COLD PROCESS MORE LIABLE TO GRANULATE?

"It has been said that the percolated syrup, Mr. Salisbury, is less liable to granulate. Do you think this cold-process feed will be as free from such trouble, or will it be as good as the syrup made over the stove?"

"I never have any trouble with granulation in the combs, and I have used this plan a number of years now. The fact is, when the syrup is made over the stove the heat in itself has a tendency to make the water take up more sugar than it can hold in solution when *cold*."

"That's so," said I; "and when the water is cold in the first place it will take up no more sugar than at any other time."

In corroboration of this I may say that none of the cold-process syrup we fed last fall showed at any time granules of sugar, while we have noticed in times past that syrup prepared by the aid of artificial heat often did show such granules. As Mr. S. says, the heat enabled the water to hold more sugar in solution than it could when cold.

I have thus gone carefully into the details of the conversation, as it explains *how* to make good syrup by the cold process, and how I was misled in thinking that the air-bubbles, by the extractor plan, were granules of sugar in my first tests, when they were only *air-bubbles*.

Of course, making syrup by means of mixing sugar and water together is not entirely new; but the possibility of doing it so expeditiously, and making it as clear and as good as that made by artificial heat, is new, I think. I am aware that there is a general impression that a mixture of cold water and sugar will be more liable to granulate in the combs; but after the reader has thoroughly considered the matter in the light of the paragraphs just given, he will acknowledge it must be even better—at least from a theoretical standpoint. So far as tried by Mr. Salisbury and ourselves, it is just as good in actual practice.

HOW TO USE THE ENTERPRISE MEAT-GRINDER; HOW TO COOK THE MEAT AFTER IT IS GROUND, ETC.

As we have many questions in regard to the meat diet, one of our women-folks was requested to answer in full, and here is what she has to say in regard to the matter:

We had trouble in grinding the meat when a member of our family was dieting a couple of years ago. It seemed impossible to get the meat through more than once, and the plate had to come off every few minutes and be cleaned out. But we have found a way out of the trouble. If you will screw the plate on very tight, take a hammer, and pound it down after you have screwed it as far as you can with your hand, you will have no further trouble. The meat will be forced through in a continuous stream, and you can put it through three times without taking the plate off once to clean it, and you can do it in less time than it took you to do it once.

In regard to broiling the chopped beef, you will probably have to learn somewhat by experience. Make the chopped beef into a loose cake—as loose as you can without having it fall apart in broiling, and lay it on a common wire broiler, and hold it over a gasoline or gas flame, turning it often till it is done. If you do not have access to a gasoline stove, very hot coals will do nearly as well. Have a hot plate near at hand to catch the juice which may run out when the meat is turned. If you have trouble in getting it done through in this way, just sear it over on both sides and turn it on a hot plate and set it over water until it is done. Be sure to cover it if you put it over hot water, so that it will not dry out. Baking it in the oven is not a good way, as it tends to dry out the juices of the meat and make it indigestible.

ON THE WHEEL.

After a busy day there are few things I enjoy more than sitting down at my secretary—yes, it is *my* secretary—it is a particular one where my agricultural books and papers are all together; and when it is too dark outside I can just sit down there with a nice lamp and take real solid comfort. Well, a few days ago I picked up the *Practical Farmer* for Oct. 5. I always read what Terry writes, whether it is on clover, wheat, or even cattle. Any subject that interests Terry always interests me, for I find some practical hints that are worth money in any kind of business whenever he undertakes to talk to the people. Well, just about the middle of his article I noticed he put in a headline—

BLOOD WILL TELL.

It interested me so much that I am going to copy a part of it right here.

Yes, blood will tell, no matter whether it is in stock or seed. Last spring, Wm. Henry Maule, the great seed-man, sent me two small tubers of a new early potato to test. They weighed less than half a pound, the two together. There was nothing in their appearance to indicate that they were better than any ordinary potatoes one could pick up in any farmer's cellar. I have a good many potatoes sent me to test in this way, and often find that they are no better than old varieties. We had a number on trial this year. To make the trial more complete, I got two tubers of about the same size from an old farmer's stock, and planted them by the side of the others. He said they were Early Rose. I can't say about this, but they are an early kind that he has grown a long time without any change of seed. All these potatoes were cut to one eye, and planted precisely as the rest of our field crop was planted. They were put right in the field, and not on selected ground, but on average. No manuring or fertilizing whatever was done on the land where they grew. Nor did they have any extra tillage. We dropped these pieces in drills made the same as all over the field, and then treated all the field alike till digging-time. I took a fork and threw out the hills planted with Mr. Maule's new early potato, and I never was so surprised in all my life at any results obtained in potato culture. In every hill there were great, large, beautiful potatoes, such as I have never seen since the first year the old Early Rose came around. There were practically no small ones, or medium sized ones—just enormous ones, such as you might perhaps look for under very favorable conditions in a wet season. Now, I am not exaggerating a bit. The first year I grew the Early Rose there were a good many tubers as fine and large as these. I have never seen any early potatoes on my farm since, as one, until I dug these. There were 45 pounds. They resemble the Rose in shape, color, and quality very much. They are quite early, and were ripe entirely before the rains came, so this great growth was made with little chance. The tops were not large. They were not as thrifty and promising as the Freemans, hence my great surprise when I dug them.

The two tubers obtained from a farmer's cellar gave me 15 lbs. of rather small potatoes. There were hardly any that you could call medium, and many small ones. The two lots were each given about three hills less than half a square rod to grow in. The yield per acre of Wm. Henry Maule's potatoes was over 240 bushels. The yield of the others was over 80. Here was a difference of 160 bushels per acre, due entirely and only to blood. In other words, the vigor and vitality of the new seedling enabled it, under precisely the same conditions, to grow three times as many bushels. Now don't think this is an advertisement of Wm. Henry Maule's potato. He has never written me a word about it. When I planted the tubers I thought in all probability I should never have any occasion to mention it. But there is a great lesson taught by this little ex-

periment. Thousands of farmers are using seed that has so run out that there is no profit in growing the crop. I would not be rash. I am pretty careful myself. But you will make a mistake if you don't change seed occasionally and get the benefit of new blood. In this line of new potatoes we are constantly testing, and quick to change when it will pay. We raised the Early Rose largely 10 years; but careful tests made us change to Early Beauty of Hebron, Snowflake, Monroe Seedling, etc., as these newer varieties came out. Do you know the night after I dug those 45 pounds of new potatoes I hardly slept at all? My potato blood was so stirred up I couldn't cool down.

Well, the above little story so stirred up my "potato blood" that I could hardly wait till the next morning. Do you know why? Because I determined to make Terry a visit on purpose to see that 45 lbs. of potatoes. Furthermore, I decided it was the potato I wanted for some experiments I am getting ready for in the way of growing early potatoes under glass. I could have ridden the whole distance on the wheel; but it takes almost too much time, and just now we are very busy here at the Home of the Honey-bees. I accordingly took the first train for Akron, 20 miles away. Then I asked if I could put my wheel on the electric cars.

"Not unless you pay for the wheel also."

"All right. But how much must I pay for the wheel?"

"Ten cents for yourself, and the same for the wheel as far as the power-house, where our run ends."

"All right, and many thanks. Why, if you will only carry our wheels along with us for the small sum of 10 cts. additional, we will patronize you often, and the wheel business and the electric-car business will go right on lovingly together."

These electric cars are warmed by the same subtle fluid that propels them. Under every seat in the car there is a simple coil of wire. The coil is open so the air can circulate all around. The wire is of such a size that the amount of current sent through it makes it hot; and this diffuses the most pleasant and agreeable heat you can imagine all through the car on a frosty October morning.

At the power-house the line from Silver Lake to Cleveland starts out. I went into the office and tried to make arrangements with them to carry my wheel with me, but they absolutely refused. They said I could have the wheel sent on a freight-car that runs along later. I explained that I should have to have the wheel as soon as I stepped off the car. But it was of no avail. Why will great corporations be so stupid? Is a wheelman going to patronize an electric road and then sit down and wait for his wheel to come up after him, waiting longer than to have ridden the whole distance with the wheel? The consequence was, I rode eight miles to get to Terry's, and then a visit of only fifteen or twenty minutes; for to reach home by night I must get back to the power-house at just such a time. But I saw that new early potato. They were down in a dark cellar, in a bushel basket, with a big tub turned over them so as to be sure nobody got those precious tubers for dinner, by mistake. I wanted one of those potatoes very badly. I would have given a dollar for just a little one; but I knew beforehand that friend Terry would neither sell nor give away even the smallest potato without Maule's consent. He said that Maule had not told him any thing about the potato at all; neither had he told him what to do with the product. He simply asked him to test them. They had not tried any of them for eating, for they are too valuable. I do not know what some of them might

weigh, but considerably over a pound, I should judge. And this great yield was without any particular show of tops. In fact, the tops were not as large as those of the Freemans right beside.

I was satisfied with my visit, and started back on my wheel with more enthusiasm than when I came. By pretty hard riding I managed to reach the power-house just as the conductor was calling out "all aboard." Next morning I wrote Maule a letter; but 24 hours after, considering the matter, I wrote another, begging for a few of those potatoes at some price. I told him I *must* have them at once. The first letter did not bring more than a promise that, when his new catalog was out, I could have some at catalog prices. My second one, however touched the spot, and the result is, I have actually purchased five barrels of this new potato. They are to be called Maule's Early Thoroughbred potato. The price for the coming season will certainly be a dollar a pound, or perhaps \$1.50. I paid so much for these five barrels I should hardly dare tell anybody about it.

So you see I got the coveted potato I wanted so bad. What shall I do with them? Well, a few will be cut up and started in the greenhouse at once. I am going to see if I can not have some *new* potatoes ready to plant by planting-time next spring. The rest of them are not for sale, but are to be given to subscribers to GLEANINGS. And this is the way we will do it: Every one of our readers who is now a subscriber to GLEANINGS, who will send us \$1.00 for GLEANINGS one year, not asking for any other premium, shall have one pound, postpaid by mail, of Maule's Early Thoroughbred potato. The potatoes themselves are *worth*, say, a dollar a pound, but they are not for sale at any price. If you do not want to take the trouble to get a subscriber to GLEANINGS, make some of your friends, who you think would be interested in it, a present of it for one year, and we will send you the pound of potatoes.

Perhaps you do not realize how much of a find this new potato is. It is very early—perhaps as early as anything we have. None of our other exceedingly early potatoes are good yielders. This is a tremendous yielder, and the tops are small, so it will be just the thing to grow for early potatoes under glass or under beds covered with cotton sheeting. Below is what Maule himself has to say in regard to quality:

In regard to the quality of Maule's New Early Thoroughbred potato, it is exceptionally fine; it is as good a baker as Brownell's Winner, which heretofore has been considered the best of all for this purpose; and for every other culinary purpose it is simply perfection. You can not recommend it too highly.

WM. HENRY MAULE.

Philadelphia, Pa., Oct. 19.

We have at this date, Oct. 19, received 1 lb. by mail, from Maule. One of these potatoes was cooked, together with some of the Freemans. While the Freeman is perhaps a little more dry and floury, the new potato was pronounced by all the family to be richer and sweeter than even the Freeman. Take it all together, I believe that, with all its other good qualities—earliness and wonderful productiveness—it is the crowning triumph of the present day in potato-growing.

With this fine *early* potato, and the Craig Seedling for a *late* one, we have a pretty nice "span." Don't you think so?

FLORIDA NOTES — CONCLUDED.

I have once before mentioned my visit to the branch experiment station at Fort Myers. This was instituted in order to test Florida products away down below the frost-line. The experiment station proper, however, is at Lake City,

Columbia Co. Here I met with a very cordial reception from Prof. Clute, formerly connected with the Michigan Agricultural College, at Lansing. They have a fine school here, and beautiful grounds; and quite a good deal has been done in the way of testing not only fruits and vegetables, but the various grains that can be profitably grown in the northern limits of the State of Florida. Prof. Clute was enthusiastic about the flat pea, or *Lathyrus silvestris*, which has made such a wonderful growth on their grounds at Lansing, Mich. I believe it was he who first introduced and tried on an extensive scale this plant. The scaline had also been making a growth of one year on the experiment grounds; but the frost had cut it down; but when I was there it had started out making rank shoots not unlike asparagus. These shoots were several inches in length. Quite a plantation of the flat pea was just up, and was growing enough to show the nitrogen-nodes. I had quite a pleasant visit with Prof. Rolfs, the State Chemist. The different professors showed great willingness to drop every thing and show me their work and their plans. This institution is so new in Florida that they have not as yet made a success of many of the experiments, as we have here further north, where experiment stations are an older idea. My stay was so brief that I did not have time to go about much in the country.

Around Lake City, as in other parts of Florida, we find many of those strange sink-holes that have interested me so much from time to time. Gear's Sink, near by, is filled with beautiful clear water, indicating that these artesian wells and lakes have at least some connection with this sinking-down of the ground. Naturally, Florida has not very much to offer in the way of waterfalls; but Falling Creek, in the vicinity, is certainly as handsome and picturesque as some of the falls further north. A beautiful clear pure water that characterizes almost every part of Florida is one of the pleasant things about it. In fact, I can not remember of having seen any muddy water anywhere; and, I might almost say, for that matter, no mud anywhere. Another sink-hole, called Falling Creek Sink, interested me. The ground has gone down, carrying with it trees, logs, brush, etc., making it look as if the bottom indeed had commenced to drop out of every thing. The turpentine industry flourishes to a greater or less extent all through this region. This has been described before.

A few miles out of Jacksonville, toward the west, one is astonished at seeing a considerable town of very hastily built cabins, now entirely deserted. What could it mean? My curiosity was finally satisfied by some of the passengers telling me that it was a camp started at the time the yellow fever was raging, people rushing for the country, and getting along as best they could until the epidemic had passed by. And now it makes one feel a little sad to see quite a good-sized town so still, silent, and desolate. Probably there was nothing in the location to induce people to stay, other than the fact that it was a safe distance from the contagion of the terrible epidemic a few years ago.

During the middle of March I started back for my northern home. There are many pleasant things about Florida; but I confess that, as I got on further north, it seemed exceedingly refreshing to see *large areas* of cultivated fields. In Florida, farming and gardening of all sorts is mostly done in the favorable places here and there. The greater part of almost every locality is still wild and uncared-for.

Some years ago an old song was quite popular, called "The Girl I Left behind Me." I be-

lieve it met with more favor with the young or middle-aged; and it might seem out of place for a man of my age to be letting his thoughts run a good deal in the direction of "the girl I left behind me." Yes, every mile I passed reminded me that I was so much nearer, not only the girl I left behind me, but the other girls and boys flocking around her, to say nothing of the grandchildren; and my heart overflowed at the thought of meeting them all again after an absence of two months. I fell to musing a good deal, and I don't think I was as talkative as usual; but in coming through Georgia I overheard some of the young farmers talking about planting for watermelons. Said I:

"Why, do you dare plant watermelons as early as this, especially when you are having such severe frosts?"

"Why, stranger, some of us have found that it pays to plant very early. If the weather should swing around favorable, and these early-planted seeds grow, we are that much ahead. But we do not place very much dependence on this very early planting, however. Most of the large melon-growers commence very early, and then put some more seeds in the same hill, say every week, for several weeks. If the first and even second planting is killed, then the third will probably come on all right. The seed costs but little; and at this season of the year, when we have not very much to do, the time costs but little, as the hills are a good way apart; and in this way we make a sure thing of reaping the advantage of an extra-early spring if we should have one."

Now, friends, is there not a big idea here?

As I go over that pleasant visit of two months, and think of the friends I found there, I feel a great longing to go over the same ground once more. There were several points that I did not explore to my full satisfaction, because of poor health. Providence permitting, I may at some future time give you some further glimpses of that land of flowers and sunshine. Let me confess to you that, when I kneel down at night, after the cares of the day are over, I can ask God's blessing on the friends away down in Florida, with a better understanding of the matter than I ever had before.

OUR HOMES.

Jesus then cometh, and taketh bread, and giveth them, and fish likewise.—JOHN 21: 13.

And they gave him a piece of a broiled fish, and of a honey-comb. And he took it, and did eat before them.—LUKE 24: 42, 43.

I have been teaching the "meat cure" pretty vehemently for some time back, dear friends; and after Ernest backed me up on it as he did, I confess I felt somewhat anxious. Suppose I am making a mistake. Suppose the good friends who have been cured, together with myself, have unconsciously got into that state of mind, like the Electropoise patients, and that I am really doing the thing I have so strongly condemned, of *imagining* a good deal. It would indeed be a serious matter. I have prayed earnestly over it. For four years of my early life I was a vegetarian. I have by no means forgotten the arguments I used then. I often think of them; and I have prayed that God would open the way to discover if some *vegetable* product might not be found that would do all lean meat does, and thus avoid, at least in part, the taking of animal life.

After a slight attack of my malarial chills last summer I said to Mrs. Root, "If there is a

doctor on earth who can get me out of these troubles I would willingly give him \$1000;" and I *prayed* over it—not for my sake alone—of course not—but for the sake of suffering humanity whom I try to teach "doctoring without medicine." God has answered that prayer, or, at least, it seems so; and it didn't cost \$1000 either. Of late I have been pleading with the great Father again. I have asked him if it were not possible that we might enjoy the fruits and grains, so luscious and plentiful, at least in moderation, while we secured health.

Little by little as I prayed, my mind began to turn toward the great sanitarium of Battle Creek, Mich.—toward the peculiar people who live there, and who not only live on vegetable diet, but who persist in having their Sunday on Saturday. May be the idea was suggested somewhat by the fact that we had received an order from them for a carload of stuff for boxes to contain their "health crackers," etc. I said again to Mrs. Root, "Dear wife, I would give another \$1000 to know how to keep well, and to teach others, if it could be done, and still allow them to have bread and butter, peaches, baked apples, etc."

As Battle Creek stands at the head in this, I felt it might really be a duty to visit there—a duty I owed to the readers of GLEANINGS, to pay them a visit, that I might not lead them into error. If I am to teach "doctoring without medicine," *surely* I ought to see both sides of every phase of the matter.

At this crisis a letter came that almost seemed to have the finger of Providence in it.

Dear Friend Root:—I have wanted to have you come here and see how our institution is run, ever since I have been here; but I felt as if I was a cracker from the Flatwoods, that I did not care to say too much about it; but in some way your work was mentioned the other day before some of our managers here, and that brought up the subject of A. I. Root. Of course, we are interested in any thing that will forward educational work, and lead to better living and happier homes and happier people. The management instructed me to say to you that, if you would come here and visit us, we would furnish the transportation, and consider you our guest while here, and I should be pleased to have you come and see a business that is conducted without a view to money-making, but whose entire profits are to be used either in the betterment of the plant or in charity. We have a family now of about 1200 people, patients, guests, and helpers, and I think it would do you good to come and see some of our meetings. IRVING KECK.

Battle Creek, Mich., Oct. 8, 1895.

I replied at once, accepting with thanks the kind invitation, of course declining to let them pay any of my expenses, for I always want the privilege of speaking through GLEANINGS without bias, unprejudiced by fear or favor. On the 22d of October, as I stepped from the train I was glad to see the friendly face that greeted me so kindly last winter at Bowling Green, Fla. Little did friend K. or myself expect, when we parted away down at Bartow, Fla., to meet so soon, and under such changed circumstances. But I must hasten. At the Battle Creek Sanitarium it is the custom, once a week, for patients and others who may wish to attend, to be instructed by Dr. Kellogg in regard to health questions. Questions are sent up by the audience, and Dr. K. answers. It was my good fortune to be present on just the very evening of one these health-lectures.

Of course, I drank in every word, and I did it with almost as much intense interest as I pursued the subject of bee culture years ago. I am going to try to report the teachings of the evening pretty fully, as I am sure they are of interest and value to all; and may God give me grace to lay aside all my own prejudices (if

I have any), that I may fairly and candidly consider the whole matter. The first question was in regard to the cocoanut as an article for food. As the answer does not particularly concern us just now, we pass it by. The next was:

"What will the world use as a substitute for leather if we stop using animals for food?"

I at once surmised that at least *most* present took it for granted that the teacher was opposed in toto to the taking of life in order to furnish food to humanity. The answer was given quite at length, and in it Dr. K. in strong terms advocated his belief. As a surgeon and physician, perhaps Dr. Kellogg has few superiors in the world, and very likely he is ahead of the whole world in devising means for preparing the products of the field for healthful and delicious articles of diet; but I soon decided in my own mind, that, like some other great men, he has an offhand and sometimes even reckless way of making statements. He closed his answer by saying we could dispense with leather very easily, and that common paper, even the slip with the question on, that he held in his hand, could be made stronger and more serviceable than leather by simply immersing it in acids, sulphuric and nitric. I think he said Germany was even now making shoes of paper, much superior to leather. Now, the last may be true; but the former I am sure is a mistake, or a great exaggeration at least.

The next question was in regard to a remedy for sour stomach.

The doctor said there were two kinds—one the result of fermentation of the food, the other a surplus of gastric juice. I was a little surprised to hear him at the outset state that the Salisbury diet of lean meat was one method of cure; for pure lean beef, as it contains neither starch nor sugar, could not take on fermentation. At one period, years ago, he himself used the treatment largely—perhaps as many as a thousand patients in all, his own wife being one among the number;* but of late years he had abandoned it. He gave several of the reasons that induced him to give up the treatment. First, a sour stomach never kills anybody. I was surprised at this declaration. If this is true, diseases which we have most of us supposed to result from sour stomach *do* kill, and I confess I hardly see how a patient is going to build up very fast with fermenting substances filling the stomach and bowels. Secondly, an exclusively lean-meat diet, long continued, renders the patient unable to eat and digest anything else. This has been far from my experience and observation. Finally he said a meat-diet makes people "ferocious." This does not accord at all with my last Home Paper. The lady who superintends the juvenile department of our Medina schools has become the very reverse of "ferocious" under the meat diet. For the first few weeks, I grant, the patient feels weak and irritable; but with good digestion that comes in time, and *good blood*, come patience, gentleness, and all the Christian graces.

He said, further, if it were not for the heavy doses of hot water prescribed to rinse off the poison, such quantities of lean meat would prove fatal to the patient. It happens, however, that I was a Salisbury patient on clean pure meat over 20 years ago, before the advantages

of hot water had been discovered. I then drank water as I pleased—drank it cold or not at all, and turned out to be a pretty "tough and lively corpse" at the end of 18 weeks. At that time I was told to eat what I pleased, but to be careful about getting back into the old rut again.

It seems a little sad that two great men, both benefactors to the human race, should disagree in this way.

In regard to the excessive use of sugar, they agree exactly. The same may be said in regard to fats and greasy food; and in the great dining-hall for the helpers I found one table where they had discarded cabbage, turnips, potatoes, etc., as being unwholesome and indigestible. You see in this they agree with Salisbury and Lewis exactly. They also agree in regard to the value of whole-wheat flour, the importance of cooking rice and other grains a long while, say several hours, for the use of those with weak digestion, etc.; but more of this anon.

The last question of the evening was in regard to the use of honey for food. Our readers will recall some of the severe strictures from Dr. Kellogg, that went the rounds of the papers some years ago in regard to the matter of honey as food. Well, the teacher frankly admitted he had changed his mind in regard to honey. Some recent experiments with diabetic patients has revealed the fact that, where a liver is so much diseased that it refuses to eliminate pure cane sugar, it will still fulfill its office on honey—that is, where *sugar* would be almost fatal to a diabetic patient, he can eat good honey almost with impunity. You may recall the fact that I have written of a similar experience of my own, in regard to the use of honey. Will our readers having impaired digestion please try dispensing with sugar, and use good honey instead? If your honey is not first-class, make it so by *sterilizing*, or, in other words, heating, not enough to injure it, but so as to kill even imperceptible fermentation, and make it wholesome.

On my first arrival I inquired about hot water.

"Oh, yes! here it is," said friend Keck, "as hot as you want it, and *distilled water* at that;" and I found most beautiful drinking-fountains, right in the way of convenient access, dispensing pure water, either hot or cold, at any time of day or any season. I can't tell you in this issue all this great institution is doing for the health of humanity; but I am going to tell you of friend Keck's special department. He superintends the factory where the health foods are made. These are almost all the work of Dr. Kellogg's untiring and active zeal in devising means to make sick people well.

Some time ago I asked Dr. Lewis about their gluten biscuit, and he said they would be an excellent thing for patients to take after they are able to take some vegetable food with their meals. Friend Keck gave me a beautiful room after I had been through the cracker-factory, and, after my usual nap, I was served in my room with about the nicest steak I ever found anywhere. As I am now allowed a slice of graham bread with my meat I decided to try a dish of gluten mush instead. Pure gluten is a vegetable food containing neither starch nor sugar; but as I am allowed a little graham bread I chose the 40-per-cent gluten meal. Now, I have long imagined there might be a food product in the world that would be rich and nourishing, easily digestible, and something I could take safely with my meat. As I looked at the gluten mush, it seemed as if it were going to "fill the long-felt want." I tast-

* Permit me here to call attention to a common and, it would seem, a wide-spread fallacy. Neither Dr. Lewis nor Dr. Salisbury has ever prescribed or recommended raw beef; and yet even Dr. Kellogg more than once uses the expression, "the Salisbury raw-beef diet," or something to that effect. It is true, he once partly corrected it. Now, if he in his treatment gave his patients raw beef, he certainly was not following Salisbury.

ed it. I turned with an exclamation of surprise:

"Why, friend K., this is the most delicious food. I verily do believe, that has ever passed my lips."

I knew, almost without trying, that it would digest perfectly, and it did. In the process of manufacture it is cooked for hours, again and again; and, therefore, when put up ready for market, the addition of a little boiling water makes a nice cooked food almost instantly. The gluten biscuit I found equally palatable, but it is more trouble to masticate them. Gluten may be called the "beefsteak" of the wheat; and when cooking it smells very much like savory meat.

I had quite a talk with Dr. Kellogg in his private office. While he did not say in so many words that gluten foods might entirely take the place of lean meat, he implied that they now succeeded in treating all diseases with a vegetable diet. Be it said to their credit, very few drugs or medicines are used at all. The whole great institution, employing almost every known art and appliance for the cure of disease, come the nearest of any thing I ever saw or heard of to a system of really—"doctoring without medicine."

WHEN DOCTORS DISAGREE. WHO SHALL DECIDE?

Dear friends, there is not space in GLEANINGS to discuss the matter of a mixed diet, or one purely vegetable; for great books have already been written on both sides of the subject. May I simply call attention to the fact expressed in the text at the head of this talk? Once or twice our Lord and Savior Jesus Christ saw fit to provide food for his followers. He fed the multitudes, as you are aware, both with loaves and fishes—very likely because that was the common every-day diet of the times. Once more, he at one time provided a little banquet on the shores of the lake for the chosen few. He had first helped them to catch the fish, then he provided for the tired and hungry laborers a little meal, and it was composed as before of bread and fish, both together. At another time, when he was trying to convince them that he was not a spirit, but really flesh and blood, he asked them for food. They brought him some fish and honey, of which he partook. One of the great objections made to a diet of animal food is that it necessitates the taking of animal life; but the Saviour actually helped, by miraculous means, that his disciples might gather in that great draft of fishes. He at least evidently did not consider it sinful to take life in order to provide them with their daily food. Shall we not drop the subject here, letting each one decide for himself where duty lies? and I should say, shall we not thank God for every little bit of progress that is being made in either vegetable or animal diet. In the prevention and cure of disease—especially while this sort of cure was brought about by "doctoring without medicine"?

OUR CROP OF CRAIG SEEDLING POTATOES FOR 1895.

The ground was occupied by potatoes last year; and had it been any other variety than the Craig we should have been afraid of the scab. Let me say here that the crop is mostly

dug and harvested, with scarcely a trace of scab in the whole lot. The potatoes were planted May 10, on something over an acre of ground. As there were different patches here and there, vacated by other crops, it is hard to get at the whole area exactly. The largest piece, however, was, as nearly as we can measure it, $\frac{1}{2}$ of an acre. In consequence of a frosty spring, or some other reason, there was not a full stand. Perhaps the seed was slightly frosted, as it was shipped pretty early in the spring. We cut the potatoes to one eye—mostly large potatoes. The ground was worked up fine, with appropriate harrows before plowing, then plowed and fined up again, making a mellow seed-bed nine or ten inches deep. The ground was in good order, and they came up quite promptly—that is, what came up. So many failed, as I have told you, that, fearing the ground would not be all occupied, I planted Burpee's bush lima beans where hills were missing. I did very foolishly, however, in that; for, before digging-time, the ground was so covered with the Craig potatoes that the beans were literally choked out, and they really amounted to about as much as so many weeds. As the ground had no manure, about the time the tops so nearly covered the ground that it would have been impossible to cultivate much further we mulched all the spaces between the rows with coarse stable manure; and this, together with the great mass of tops, held the moisture so well that, after the first heavy rain, it kept at least *damp* during the whole dry season down under the mulch. About the first of October the greater part of the vines, when stretched up to their full length, came up to my chin—some of them as high as my head. The mass of foliage was tremendous; and so were the potatoes tremendous. While picking them up we put some of them into a bushel basket, for photographing. Forty potatoes made a heaping bushel; and from the whole $\frac{1}{2}$ of an acre we gathered a good 250 bushels. This would be at the rate of 400 bushels per acre, and that, too, with so many missing hills that we should have had quite a crop of lima beans if the rank growth of potatoes had not actually crowded them to death before the beans were quite matured. We got some beans on the outside rows—that is about all. The potatoes have now been tested through two of our most trying dry seasons, and they fully sustain their reputation for standing drouth, scab, bugs, and blight, better than any other potato I know of. In fact, it has never shown a particle of blight. By mistake in planting, one row was left after the seed was all gone, and this furrow was pretty well down through the middle of the patch. A new potato that we wished to test was put in here—in fact, several new kinds were put in, right adjoining the Craigs. One after another showed blight more or less before the season was over, and this one long row was all black and dead when not a leaf of the Craig foliage on either side was affected at all. The Craig is in *shape* much like the Rural New-Yorker, and is in every way fully as desirable. We think it of a finer quality as a table potato, and a very much stronger grower, both in foliage and yield.

CRAIG POTATOES AT THE OHIO EXPERIMENT STATION, ETC.

Friend Root:—I was very much interested in your account of your visit to Fenn's, Terry's, and Chamberlain's, in the Oct. 1 GLEANINGS. I thought you would be interested in hearing how the Craig Seedling behaved at the station, and your account brought it to my mind.

I can say that we had no variety out of over

one hundred kinds but showed signs of blight by the middle of August; and by Sept. 1st all were dead or practically so. The Craig held out as long as any kind, but had to give up long before any frost. We had an acre or so of different kinds planted about the first of July, and they went before the frost came. Even a few planted the 26th of July did not wait for the frost. Now, just why the blight should be so severe with us here in Wayne Co., and twenty miles north be almost free from it during the latter part of the season, is something I can not explain. The two seasons before this potatoes did extraordinarily well during the latter part of the season.

I undertook quite an experiment in the late planting of potatoes this year; and although it has turned out just as I expected, there have been some facts learned that I think of value. One is, that potatoes that grow until the frost kills them are of more value for seed than those killed by the blight. We found that such seed potatoes throw up a few vigorous stalks, while those that were blighted would have many small slender stalks. The consequence of this is, that the potato from the late-planted seed would give a much larger per cent of large potatoes than would the others. I think I am safe in saying that your Craig Seedlings, that have grown through the summer without blight, are worth much more for seed than ours which have blighted, although we have some very fine Craigs notwithstanding the blight.

Some varieties behaved differently from others in this respect. If you can spare any of the kind that grew until frost came we should be glad to get them, so as to carry on this experiment another year.

I hope you will publish the exact yield, and the amount of ground occupied by that crop of Craig potatoes.

When I was at the Medina fair I had some specimens of the green and yellow soja beans. Several farmers were quite interested in it, and asked where they could get the seed. I told them that perhaps the A. I. Root Co. would keep it in stock; if not, they can get it of T. C. Wood & Co., seedsmen, Richmond, Va.

I believe this bean is a decidedly better forage-plant than many that have been introduced with a great deal of advertising. On the station ground this year one ton of green feed was cut from a tenth of an acre. E. C. GREEN.

Wooster, O., Oct. 7.

[Many thanks, friend G. There was no blight in our Craigs at all. They stood right up till the frost, just as you saw them. So our seed will be entirely from potatoes free from blight. Come to measure the ground with a tape-line, there was not nearly two acres all together. The largest piece, measured accurately, showed $\frac{2}{3}$ of an acre, and from this we got 250 bushels, at the rate of an even 400 bushels per acre, as I have told elsewhere. I shall be glad indeed to furnish the soja beans. If there is more than one variety, tell us exactly the kind that gave you at the rate of ten tons of feed per acre.]

My answer to your request to communicate results about the Craig potato is as follows:

I procured of you last spring $\frac{1}{2}$ peck of seed. I cut them into single eyes, and planted on the side of other potatoes. They took a single row of 175 feet. Yesterday I dug them. There was a little more than three bushels; weighed from 19 ounces down; very few small ones; free from blotches and such things. They are the best potatoes I have. I shall plant all I have next year. S. W. SALISBURY.

Independence, Mo., Sept. 30.

I tried thy potato called the Craig; and from thy pound I raised nearly one bushel. The season here was the worst known for years. The blast struck very early; some crops were ruined. The Craig grew very profusely, very large vines; resisted blight the best of any I noticed. In fact, they were green when all other varieties were dead. JACOB ALMY.

South Portsmouth, R. I.

Those Craig potatoes that we purchased of you last spring are very nice. You say the vines stay green till frost comes; but that is not the case with ours. They are all dried up now. But I guess the reason of that is we planted them when we did our early potatoes. We planted half a peck of small Craig potatoes; and when we came to dig them this fall we got four bushels and a half of nice big potatoes; but they were in rich ground. We like them on account of size and good flavor.

We have now 115 colonies of bees. I have ten of my own—all but one in your Dovetailed hive, eight frames.

We have a pretty fair crop of honey this year, but it is all from fall flowers.

Savanna, Ill., Sept. 24. CHAS. D. HANDEL.

The one pound of Craig potatoes I purchased of you yielded $\frac{1}{2}$ bushel, but quite a lot of small ones. They had a very poor chance, a pear-tree shading part of them.

Tidal, Pa., Oct. 19. SAM'L HEATH.

In the August 15th number of GLEANINGS was something for which I desire to thank you, under the heading of "Sub-irrigation vs. Tomatoto." I have been trying to introduce a system exactly the same, for the house we have lived in here for a number of years past, but without avail, as the owners are not ready to listen to any thing different from what the plumber has to offer them. They are very well satisfied to run waste water from the sink to a well situated some distance down in the garden, away past every thing growing in the garden—no opportunity for watering unless we pump cold water from the well direct.

East Downingtown, Pa. FRANK T. HOOPE.

PRICE OF GLASS, AGAIN.

When we made the announcement in last issue, of a large advance in price of window glass, we were not cognizant of the fact that the manufacturers' list price had been changed recently. Since we have the new list to which present discounts apply we find present prices not nearly so high as indicated, though quite a little higher than last spring's prices. In view of this change of base we revise again our price of glass to the following:

Small sizes cut to order will be \$2.50 per box of 50 feet. Strips in stock as follows:

	Price of		Wgt. of
	10	100	100
3x17 $\frac{1}{2}$ for 24 single-tier and 48-lb. cases.....	25	2.00	50 lbs.
3x13 $\frac{1}{2}$ for 12 and 24 lb. 3-row cases.....	20	1.80	45 "
2x9 for 12 lb. 2-row.....	8	.60	20 "

CARLOAD OF ALFALFA HONEY.

There is a carload of alfalfa honey on the way to us from Reno, Nev. It is chiefly extracted, of good quality. There is some comb; but as we have orders already waiting for several tons of choice comb honey, we are likely to close this out soon.

after the car arrives. We offer the extracted at the same price we have been selling California white-sage and Michigan willow herb, or clover and bass-wood honey. We can furnish any of these in 60-lb. cans, two in a case, at 8c per lb.; two cases or over, 7½c. Write for price on large quantities. Offers of choice comb honey solicited.

HIGHER PRICES FOR WAX.

A brisk foreign demand for wax has stiffened up the price about 2 cts. a pound in the New York market. Until further notice we offer 26 cts. cash, 28 cts. in trade, for average wax delivered here. Selling price in small lots will be 32 cts. per lb. for market wax; 35 cts. for refined. Retail price of comb foundation will be 2 cts. per lb. below the printed table in our catalog. We have for some time been selling at 5 cts. below; but present prices of wax will not warrant further sales at that rate.

THE BIGGLE POULTRY-BOOK.

We have not had time to read it through yet, but we notice this one is not a bit behind the Biggle strawberry-book and the Biggle horse-book, in its wonderful half-tone pictures, to say nothing of the colored plates that are all through it. There is a sort of vein of pleasantry running through the Biggle-book pictures that is quite attractive, and the style of narration has this same vein of comicality. We take it for granted that the book is fully up to the times, because books of this kind, sent out by the *Farm Journal*, are usually so. The price is 50 cts. It contains 16 colored plates, 42 handsome engravings, and 61 others illustrating chicken-houses, nests, drinking-vessels, etc. It makes me think of the time when I walked eight miles to a bookstore in order to purchase a book on poultry. It took me a good deal longer to get home than it did to get to the bookstore, because I sat down too often to look at the pictures and to read the wonderful things in regard to my then new hobby; and that book gave me more pleasure, month after month and year after year, than I can well describe, and it gave me also some clean hard cash—the first money I ever earned in any rural industry. I verily believe the Biggle poultry-book is worth 50 cts. just to look at the pictures, even if you do not have time to read it all. You can order it at this office if you prefer. We will send it with GLEANINGS, if you ask for no other premium, for \$1.40.

HOW TO GET WELL AND KEEP WELL.

The above is the title of a book by Mrs. Elma Stuart, of "Merrie England." Permit me to say that, for many years past, I have been purchasing almost every new book as it came out, treating on the subject of health and diet. I do not mean that I have been studying all the medical works and doctor books, but those written in plain English for common people. Well, I have been a good deal disappointed to see that, almost without exception, they advocated vegetable diet, or mainly so. This book by Mrs. Stuart presents a most refreshing and cheerful contrast to the general run. She is a disciple of Salisbury, and I might say, an ardent disciple; but even the word "ardent" does not express the zeal and happy enthusiasm and pleasantry with which she tells of her trials in seeking health. She had money—at least she did in the beginning—to employ the most expensive doctors, and to go to the celebrated health-resorts; but, like the woman in the scripture, she had "suffered many things of many physicians, and had spent all that she had, and was nothing better, but rather grew worse." After gaining strength and robust health by the Salisbury treatment she took up—not medicine (because her whole system is nearer "doctoring without medicine" than any thing else I ever heard of), but she soon commenced treating others, and she has quite a long string of grateful patients to back up her testimony; and in the introduction to the book is a letter by his grace the Duke of Argyll. We find the author's picture in the front of the book, with her own autograph under it, signed, "Yours always in hot water." Her testimony is so much like my own that one might imagine she copied some of it after me were it not for the fact that the first edition of the book was put out in 1889; and in 1891 it had got as far as its fifth edition. The full particulars of the treatment are given so plainly, and in such every-day language, that it seems to me one could hardly make a mistake. In fact, I would recommend this book to all our in-

quiring friends who want to know all about the plan of treatment. And the book is so readable that I think the average person would be likely to read it all through, even though he were entirely well, and not ailing in any respect. The opening text on the title-page is, "If the prophet had bid thee do some great thing, wouldst thou not have done it? how much better, then, when he saith to thee, Wash and be clean?" From beginning to end it is a most vehement injunction to "wash and be clean," in every sense of the word.

The price of the book, postpaid, is \$1.50, and it may be had at this office; or we will club it with GLEANINGS, and furnish the two for \$2.25; or we will mail it to anybody who is already taking GLEANINGS, who will send us \$1.25.

FREE SAMPLES OF THE PREPARED HEALTH FOODS MANUFACTURED AT BATTLE CREEK, MICH., ETC.

I am happy to tell our readers that we are to be furnished with a large box of small sample packages, to be given away to those who order goods of us by freight or express. All you have to do is to say, when you make your order, "Put in some of the free samples of the prepared health foods." Each package contains full and complete directions for cooking. After you have tried them, and would like to purchase these articles in small quantities by the pound, we are going to have it arranged so we shall keep in stock the following staple articles, which will be furnished by us at the same prices at which they are sold in Battle Creek. The following is a list of the prices of the things we propose to keep in stock:

Sanitarium graham crackers, 10 cts. per lb.; wheat crackers, 10 cts.; carbon crackers, 15 cts. These latter are for constipation, and for purifying the stomach and bowels. They are made of carbonized wheat, or wheat partially burned to charcoal. Granola, 20 cts. per lb. This is manufactured from a variety of grains, subjected to continued heat and other processes whereby the starch is partially digested, and prepared for immediate assimilation. Gluten meal, 40 per cent pure gluten, 40 cts. per lb. This is what I have described elsewhere in this issue, and found so delicious when made into a mush. Granose, 20 cts. per lb. This is one of their latest and most luscious foods. It is prepared from wheat. It may be used in soups, with milk or cream, or in numberless combinations with fruit and eggs. It is palatable, crisp, delicious, and a valuable food remedy for constipation. Caramel coffee, 15 cts. per lb. This is a sort of coffee that is simply nutritious and not stimulating. You can give it to the children, or drink it yourself. Wheat-germ grits, 2-lb. package, 10 cts. Whole-wheat wafers, 20 cts. per lb. These are crisp, delicious, toothsome wafers made of whole-wheat flour, shortened with cream. Not a particle of butter, lard, baking-powder, yeast, or soda, is used in making these wafers, or in any of the crackers or biscuits. The first and main idea in their manufacture is health; next, prices as low as may be consistent with quality.

Last, but not least, we have fragments or broken crackers in bulk of all the kinds of crackers that they make, at a uniform price of 8 cts. per lb. These crackers are just as good and just as clean and fresh as any other; but they are not considered quite as nice to put up in packages, therefore they sell them at a low price as above.

Besides all the above, we have the small samples of their health food, put up in little packages, with directions for cooking, to be given away free. If wanted by mail you will have to send 10 cts. for postage; but if you mention them when ordering other goods of us, say by freight or express, we will put in some samples free of expense.

Now, they manufacture ever so many other kinds of biscuit, crackers, etc., as well as prepared foods, and you can get a nice catalog of all by simply making application to the Sanitarium Health Food Co., Battle Creek, Mich.

One special thing to recommend these foods is, that they can be so quickly prepared. The cooking is all done by steam, or by great coke fires, at the factory; and it is done on so large a scale that the cost is comparatively nothing. When you want to prepare them for the table, simply pour on a little boiling water, stir it up, and you have a hot dish of most luscious pudding, mush, toast, or whatever else it may be. Where a woman does her own housework (as is the case in our home), we should

try to make it a great study to save mamma time and steps; and with something provided so cheap, a healthful, nourishing, and delicious food can be smoking hot for the table in from three to five minutes, which is certainly a great desideratum.

COLD-FRAME OR HOT-BED SASH.

As we are now approaching the season for using sashes for protection from the frost, we call attention again to the new-style light hot-bed sash we have been using for the past two or three years. At first it was thought that such very light sash would not stand the weather and handling; but in our own gardens our boys found them a very great convenience indeed on account of their lightness. It is true, they are a little more apt to be blown off by the wind; but when placed on a nice well-fitting bed, so as to cover the bed entire, the wind rarely moves them. When used for constructing small cheap greenhouses they should be fastened on with appropriate hooks, or be held down with screws. There is a special advantage in using these for greenhouses for raising vegetables, because the movable sashes may be kept piled up, stored away out of the way until they begin to be needed in the fall; and in the same manner they may be moved in the spring, and stored away, thus giving the plants the benefit of the sun and rain as soon as the weather will permit. For all hardy or half-hardy stuff this is a great convenience.

The sash are of the regular size, 3 ft. 4 inches by 6 ft., for four rows of glass 8 inches wide. If any prefer larger glass we will furnish sash for 3 rows of 11-inch glass at same price. These sash are halved together at the corners, instead of being mortised and tenoned in the usual way. They have the advantage that they may be shipped knocked down at a low rate of freight, and they can be put together by anybody. If done securely they are just as strong as the regular sash. They are 1½ in. thick, outside bars about 3 inches wide, and inside ones about 1½. The bars are grooved to slip the glass in place. If a light of glass is broken, move them up close and slide another in from the bottom end. If any prefer the bars rabbeted to set glass in putty, we will make them so on request. In putting the sash together the best job is done with screws; but nails may be used, and are less expensive.

Price of one sash, in the flat, for sample, without glass or screws, 65 cts.; 5 in the flat, 60 cts. each; 10 in the flat, 55 cts. each. If you want screws to put them together, add 5 cts. for each sash. The holes are all bored, so you know just where the screws are to go. Glass 8x10, just right for the above, \$2.00 per box of 90 lights; 5 boxes, \$1.90 per box; 10 boxes, \$1.80 per box; less than a box, at 2½ cts. per light.

Sash put up, no glass or paint, 15 cts. each extra; 10 cts. each extra for each coat of paint, and 80 cts. each extra for glass set in place, making the sash put up, painted 2 coats, and filled with glass, at \$1.75 each in lots of 5. The risk and freight charges are so much more shipped put up with glass that we do not recommend you to order this way, and we can not well pack less than 5 safely.

We would not advise shipping a less number than five; but if you take our advice you will have all your glass sash shipped in the flat. In this case they go as fourth-class freight; whereas, all complete they will have to go as first-class, and some roads rate them as double first-class.

JERSEY WAKEFIELD CABBAGE SEED; H. A. MARCH'S STOCK SEED.

We are on hand again with another extra-fine lot of this seed now known so well. Cheap, 20 cents; pound, \$2.50. Remember this is as cheap as, and in many cases cheaper than, the seed you buy without knowing who grew it or anything about it. It is not a bit too early to make your preparations and be ready for extra-early cabbage next season.

POTATOES FOR FALL PLANTING.

For prices and full description of all the potatoes we recommend and sell, please send for our potato catalog. We offer remarkably low prices for fall shipment, and expect to be able to ship potatoes safely, by taking proper precautions in packing, clear through this present month of November—that is, unless the cold-wave signals shall seem to render it imprudent.

SECOND SIZE SEED POTATOES.

These are all closed out, with the exception of a few Puritan and Lee's Favorite. We have, however, a large stock of second-size Freeman's, T. B. Terry stock, and a limited supply of second-size Craig Seedling. Early Ohios are sold out, both kinds—firsts and seconds.

Oct. 31.—State of Maine potatoes are just sold out. We can purchase more (same lot), but will have to make the price 30 cts. instead of 25 cts. per bushel.

REDUCED PRICES ON SIR WILLIAM POTATOES.

After so many up and downs this new potato will now stand as below, and all who have sent in orders at a higher price will be charged only as follows (in new sacks or new largest-sized apple-barrels, f. o. b. at Hudson). Firsts, single bushel, \$1.10; 2 bushels, \$2.00; single barrel, \$3.00; 10 barrels, \$25.00. Seconds, of Sir William (planting size), 1 bushel, 75 cts.; 2 bushels, \$1.40; 1 barrel, \$2.25; 10 barrels, \$20.00. Orders will be filled at the above prices by W. I. Chamberlain, Hudson, O.; or, if more convenient, by ourselves at the prices given.

Kind Words From Our Customers.

The goods ordered were promptly received in good order. Every thing is perfectly satisfactory. Your hives, both in material and workmanship, *excel* all others in this vicinity. F. P. SARGENT.

San Bernardino, Cal., Sept. 4.

We are feeling good this morning because we took first and second premium on honey, and second on potatoes, at our county fair, for which we are indebted to GLEANINGS, A B C in Bee Culture, and the A B C of Potato Culture. I love to hear from A. I. Root and Tallmadge. C. A. PETERSON.

Boswell, Ind.

THE QUALITY OF ROOT'S SHIPPING-CASES.

Mr. Root:—Your 100 twelve-section three-row cases were duly received. They were at once nailed, filled, and crated, and on the 20th shipped to S. T. Fish & Co., Chicago. On the 23d they write: "Your honey arrived late last night, and we sold it this morning at 16 cts. per lb. We hope you are pleased with the price, and we must compliment you on putting up your honey, as it is as fine a package as we have received, and finer (with the exception of one man) than any one else puts up." That is what I thought of them when I put the first case together. Great minds frequently run in one channel; but when a small bee-keeper and a big commission house agree on a business matter, it must be so. The compliment is deserved by you alone, and it is but right you should know how we appreciate the fine work you are putting out. It meant for me a quick sale and an extra cent a pound. GEO. G. SCOTT.

Wadena, Ia., Aug. 24, 1895.

[See what S. T. Fish & Co. have to say about this, page 669, Sept. 1.—Ed.]

Belgian Hares! No better in America. Breeders, \$4 a pair; young, \$2. Heavy stock, first-prize buck. Stamp. W. W. KULP, Pottstown, Pa.

114 to 122 S. 6th St., Quincy, Ill.

Circulars free. Send 6c. for Illus. Catalogue.

In responding to this advertisement mention GLEANINGS.

Advantages of Bee-Escapes.

No sweat steals down the heated cheeks and aching back of the bee-keeper as the result of standing in the hot sun puffing, blowing, smoking, and brushing bees; no time is wasted in these disagreeable operations; and no stings received in resentment of such treatment; the honey is secured free from black or even the taint of smoke; the cappings are not injured by the gnawings of bees; and robbers stand no show whatever. If there are any broken burr-combs there are cleaned up by the bees inside the hive, before the honey is removed. **Leading Bee-keepers use the Porter Escape,** and say that without a trial it is impossible to realize the amount of vexatious, annoying, disagreeable work that it saves. The cost is only 20 cts. each, or \$2.25 per doz. As in the past, this escape is manufactured by the Porters, but The A. I. Root Co. has secured control of the sale for this country. Order of your dealer or of

THE A. I. ROOT CO., Medina, Ohio.

For \$350.00. One hundred 2-story hives complete for comb honey; bees and hives in good order. Inquire of **A. LEYVRAZ, Francis, Fla.**

Our Leader Pump,

For Wells and Cisterns.

We have frequently had calls for a good well-pump, but have not heretofore tried to supply the demand. Having a very favorable opportunity we contracted to have made for us 50 pumps as shown in the adjoining cut. We are using one of them in a cistern, and can testify that it is a good pump, and a special bargain at the price we ask.

Equal to pumps generally sold for \$7 to \$10. Our price is \$4.50 each; 2 for \$8.00. Quantities at very low prices quoted on application.

This pump has an adjustable base and brace, making it very easy to increase or decrease the height of the pump.

It has an improved,

reversible fulcrum or handle-bearer. This fulcrum differs from all others in that it extends downward to the bottom of the reservoir-head, forming a double bearing or support, doing away with the numerous set-screws commonly used on other pumps and which are so unreliable. The handle may be set opposite or at right angles to the spout, or, in fact, in any position.

It has steel bolts and plunger-rod, making it very much stronger and more durable than the ordinary iron bolts and rod generally used in the construction of this class of pumps.

It has an improved siphon spout and reservoir, causing it to throw a smooth, steady stream.

The pump is made with 1½-inch tubing measuring 4 feet to bottom of cylinder. We will include at the retail price 4 feet of tubing additional. Extra tubing, 1½ inch, at 10 cents per foot. Cylinder is iron, not brass lined. A brass-lined cylinder can be furnished for 75c. extra.

It may be used in wells to the depth of 20 to 30 feet, as well as in cisterns.

A \$9.00 Pump for \$4.50. 2 for \$8.00. Superior in every respect. Well-finished and durable prices in quantities.

The A. I. Root Co.,
Medina, Ohio.

PREMIUM RULES.

Please Read these Rules Carefully, and thus avoid misunderstandings.

We believe most of our readers appreciate GLEANINGS enough to continue with us without the extra inducement of premiums. These are offered with a view of increasing our number of readers by the addition of new subscribers. The premiums are intended for those who, by personal effort, secure the subscribers. These persons are almost always those who already read GLEANINGS, and know what it is. We are glad, therefore, to pay you well for your trouble. *No premiums will be given to news-dealers or subscription agents.* 1. Both renewals and new names count toward securing premiums, but we require that AT LEAST HALF the names SHALL BE NEW SUBSCRIBERS. Note also exceptions under different premiums.

2. No name will be counted for premiums unless it is accompanied by \$1.00; and in case of renewals, all arrearages, if any, must be paid up, and \$1.00 sent for a year in advance—the advance subscription only, counting for premium.

3. You can close your list of names at any time, and call for the premiums due; or you can add to the list of names. But—

4. Send along the names as fast as gathered, so that the subscribers may begin to receive the journal at once. No subscription, under any circumstances, must be received for less than \$1.00 per annum.

Mark every name or list of names, "*For Premiums,*" if so intended, and we will credit them to the sender on our premium-record.

5. *Be sure to give the Name, Postoffice, County, and State, of each subscriber and of yourself.*

6. **All sample Copies** necessary to canvassers will be sent postpaid free.

7. When you order your premiums, be **sure** to state **HOW TO SEND**, and if by mail do not forget the postage.

8. **To Foreign Readers.** To all foreign countries, 48 cts. must accompany subscription for postage.

7th.—How to Send Money.—1. Tell how much you inclose and of what it consists. 2. Money may be sent without risk of loss in three ways:

By bank draft on any responsible city bank.

By express money order on any express company.

By postoffice money order.

If you send by any of the above methods, and your order should be lost, you can get a duplicate.

If there is no bank, express office, or money-order office near you, so that you can not use any of the above methods, you may send by registered letter, and we will be responsible; but if any of the methods first named are available, we will not be responsible for money sent in any other way. Do not send coin in letters; if you do, they are at your risk.

All NEW names sent in before Jan. 1st, 1896, will receive the journal from the time the Names are received till Jan. 1st, 1897, for \$1.00, besides the premium to the person sending us the name.

THE BIGGEST PREMIUM OUT!

Two Papers For the Price of One.

The **Farm Journal**, of Philadelphia, a monthly agricultural journal of 16 pages, sent **one Year Free** for one subscription to **Gleanings**, with \$1.00, paid in advance, either new or renewal. In the case of a renewal, all arrears, if any, must be paid in addition to 1 year in advance; or with either new name or renewal at \$1.10, and this name may also count on another premium.

There are, no doubt, very few readers of GLEANINGS who do not also take some agricultural paper. Among our very large list of agricultural exchanges there is not another one as pithy and to the point as the **Farm Journal**.

It is now in its nineteenth volume, and takes the lead among all the agricultural journals of this country and of the world. It gives no chromos, puffs no swindles, inserts no humbug advertisements, lets other folks praise it, and makes good to subscribers any loss by advertisers who prove to be swindlers. The editor was born on a farm, and reared at the plow-handles, and the contributors are practical men and women, who write with their sleeves rolled up, and who briefly and plainly tell

the best and most profitable way of doing things on the farm and in the house, as learned from actual experience. This is what has sent it ahead of all others in circulation.

The regular price of this excellent journal is 50 cts. a year, and it is well worth it; but by **special contract** with the **Farm Journal** we are enabled to make the above very liberal offers.

Christ Before Pilate. We have a few of the reproductions of that magnificent painting in colors; a very fine picture, which we will send to any one who wishes, while they last, at 35 cents each, postage 10 cents extra, or free for a new subscription, postpaid, with your own renewal.

Your Choice of any Book on this page Free

To any one sending renewal subscription before the time paid for is out, or to any one in arrears who pays up all arrears and for a year in advance. Postage for mailing book must also be included. Any three of these books sent for a new subscription, with \$1.00 and the required postage.

OUR LIST OF 10-CENT BOOKS.

PEABODY'S WEBSTER'S DICTIONARY. 25,000 words and phrases, and illustrated with 250 engravings; cloth bound. This is the one we sold for years at 15 cents. We thought we had done something wonderful when we offered so large a dictionary for 15 cents, but we are now able to sell them for a dime. Just think of it! Postage extra. 5 cents.

ONE-SYLLABLE PRIMER. 6x8; 48 pages, full of pictures; something that will always be wanted as long as there are children in our homes. Postage 3 cents.

POULTRY FOR PLEASURE AND PROFIT. 48 pages, and 20 illustrations. A complete little book of instructions. It treats of the best varieties for pleasure and profit; how to house and yard; how to manage; how to feed; diseases, incubation, etc. It is a 25-cent book; but by getting 1000 of them we can sell them for 10 cents. Postage 1 cent.

THE HORSE AND HIS DISEASES. By Dr. B. J. Kendall; 100 pages and many illustrations. Over 500,000 of these books have been sold, because they are so popular and complete, for a small hand-book. It gives the symptoms of most diseases, and treatment for the same. This is another 25 cent book that we got down to a dime by taking 1000 of them. Postage 3 cents.

SILK AND THE SILEWORM. This is a complete work of instruction on silk culture, by Nellie Lincoln Rossiter, a practical silk culturist; 32 pages. Silk culture is the favorite pursuit of many ladies in our land; and all who are interested will find this little work very instructive. The price printed on it is 25 cents, but we sell them for 10 cents. Postage 1 cent.

NEW TESTAMENT, NEW VERSION. 434 pages, printed in nonpareil type. This should be in the possession of every student of the New Testament. Even if it does not come into common use, it is helpful to know what changes in translation the New Version gives. Postage 5 cents.

JOHN PLOUGHMAN'S TALES AND PICTURES. By Charles Spurgeon; 128 pages, and a picture on almost every page. John Ploughman talks plainly, and makes a good point in every talk. It is by no means dry reading, either. Postage 3 cents.

LIFE AND ADVENTURES OF ROBINSON CRUSOE. 240 pages, paper covers. Until now 20 cents. Although they cost us more than 10 cents each, we offer them at that price. 5 cents extra by mail. There are few books so universally read as this one, and there are many editions printed. At the price, this one is a bargain.

PRACTICAL TURKEY-RAISING. By Fannie Field, the most experienced turkey-raiser in America. This is a regular 25-cent pamphlet of thirty pages, giving the best information on this subject. Our price is only 10 cents. By mail 2 cents extra.

GIVEN AWAY FREE.

To any one who sends us the name of a new subscriber for 6 months, with 50 cents, we will send any one of the above pamphlets, your selection, post-

paid. For a new yearly subscription, with \$1.00, we will send any three of the above books free, postpaid; or to any present subscriber who sends \$1.00 to renew his subscription *before* the time paid for is up, or who, being in arrears, will send all back dues, and also for a year in advance, we will send free one, your choice, of these booklets.

A Dozen Attractive Pamphlets.

They are not only attractive, but so valuable and helpful that they should be read by every one who desires to improve his life, and live happier; and who does not have such desire? Doubtless many have read "The Greatest Thing in the World; or, Love the Supreme Gift," by Drummond; and others have heard of it. It is something that will do us good to read often. "Love is the fulfilling of the law;" and the more of it we can get into our lives, the better for the world and for us.

These little books are 16mo 32 pages, with handsome light-blue parchment cover, and nice, clear print. Price 10 cents each, or 90c per dozen, any one or assorted books, postpaid or with other goods. Publisher's price is 20 cents each.

1. Love, the Supreme Gift: The Greatest Thing in the World. By Prof. Henry Drummond.
2. The Perfected Life: The Greatest Need of the World. By Prof. Henry Drummond.
3. How to Learn How. Addresses by Prof. Henry Drummond. I. Dealing with Doubt. II. Preparation for Learning.
4. Power from on High: Do we need it? What is it? Can we get it? By Rev. B. Fay Mills.
5. The Message of Jesus to Men of Wealth. A Tract for the Times. By Rev. George D. Herron. Introduction by Rev. Josiah Strong, D. D.
6. The First Thing in the World; or, The Primacy of Faith. By Rev. A. J. Gordon, D. D.
7. Hope: The Last Thing in the World. By Rev. A. T. Pierson, D. D.
8. The Fight of Faith and Cost of Character. Talks to Young Men. By Rev. Theodore L. Cuyler, D. D.
9. The Four Men. The Aspect of Man from Four Standpoints. By Rev. James Stalker, D. D.
10. How to Become a Christian. Five Simple Talks. By Rev. Lyman Abbott, D. D.
11. The Dew of Thy Youth. A Message to "Endeavorers." By Rev. J. R. Miller, D. D.
12. Temptation. An address to Young Men. By Rev. James Stalker, D. D.

Drummond's Addresses.

Besides the booklets above we have Prof. Drummond's addresses, 6 in number, with biographical sketch, making a 16mo book of 140 pages, bound in board covers, part cloth and part paper, in two shades of blue, neatly figured, making a very handsome book. Price only 30c postpaid, or 25c if sent with other goods. Or we will give one free postpaid for a new subscription to GLEANINGS, with \$1.00.

SOME CHOICE BOOKS WHICH OUGHT TO BE IN EVERY HOUSEHOLD.

Illustrated Pilgrim's Progress.

We have secured some of a very fine English edition of Pilgrim's Progress, illustrated with over a hundred very realistic pictures. The book is 16mo, printed on very fine paper, containing 384 pages, and the illustrations are the most striking, and true to the characters represented, that we have ever seen in the most expensive editions. The binding is of cloth, richly illuminated in six colors, with title in rich goldleaf on back and side. There is no paper wasted in wide margins; in fact, there is so little trimming that some of the leaves have to be cut apart. It is a book of such quality and make-up as to easily bring \$1.50 at retail a few years ago. In this day of cheap books and low prices it is necessary to close out the last of the edition away below actual value. We offer these at 50c each; by mail, 10 cents extra. We will give one free postpaid for 2 new subscriptions to GLEANINGS, with \$2.00; or for 1 new subscription and 1 renewal paid in advance with \$2.00, and 10c extra to cover postage on the book. Of course, every one knows what Pilgrim's Progress is, as, next to the Bible, it is the most widely read book in the English language.

FOSTER'S PILGRIM'S PROGRESS ILLUSTRATED This is from the Charles Foster Publishing Co., Philadelphia, where the Story of the Bible comes from. The book is 9½ inches long, 7¼ wide, and 1¼ thick. It has 425 pages and 175 illustrations. Ever so many, to whom I have shown it, pronounce it a \$2.00 or a \$2.50 book; but by buying a large number of them at a time we can sell them to you for only 75 cents. This book is so heavy, however, that it can not be sent by mail for less than 23 cents, making 98 cents by mail postpaid. The covers are most beautifully embellished in scarlet and gold, and many of the pictures are worth to me alone the price of the book. Among them I would mention Christian and Pliable in the Slough of Despond; Mr. Worldly Wiseman; Giant Despair, etc. But the sweetest and best of them all to me is Prudence talking to the boys. A single glance at the book by anybody, when you mention the insignificant price for so beautiful a volume, will make him hold up his hands in astonishment. We send a book as a premium for three subscriptions at \$1.00 each; or send us \$1.75 and we will send you GLEANINGS for a year, and the book postpaid. If you want something extra nice for a present, we can send you one with gilt edges for 25 cents more.

THE STORY OF THE BIBLE. This wonderful book is

the production of Rev. Charles Foster, of Philadelphia, lately deceased. It is the whole Bible reproduced in simple language, making a book of 700 pages, illustrated with 274 engravings. It is so plainly and pleasantly written that grown people, as well as children, will hardly want to lay it down. In the hard passages in the Bible, difficult to understand, it makes a commentary that will be thankfully received by some others besides children. Indeed, it has proven so simple, reliable, and helpful, that it has been reprinted in many foreign languages. Over 400,000 volumes have been sold since it was first issued. It is a well-made book, printed on the paper. Regular agent's price is \$1.50. Our price is \$1.00; 20 cents extra if sent by mail, or given free for 2 new names and one renewal, with \$3.00, and 20c extra to pay postage.

STEPPING HEAVENWARD. By Mrs. E. Prentiss. This is a most excellent book of 112 pages, illustrated in illuminated paper covers, at 18 cents; by mail, 22 cents. Given free for one subscription, either new or renewal, and 4 cents to pay postage.

STORY OF BIBLE ANIMALS. This is another book, same size and style as Story of the Bible—704 pages, 300 illustrations. It is a description of the habits and uses of every living creature mentioned in the Scriptures, with explanation of passages in the Old and New Testaments in which reference is made to them; by J. G. Wood, author of "Illustrated Natural History." If you are interested in natural history

you will be delighted with this work. Children should read it to arouse their interest, and make them more familiar with the Book of books, by becoming more familiar with its animals. Regular agent's price \$1.50. Our price is \$1.00. By mail, 15 cents extra, or given free for two new subscriptions and your own renewal, with \$3.00, and 15 cents.

FABLES AND ALLEGORIES: or, New Lights on Old Paths. This is a most magnificent book by Charles Foster, the author of the Story of the Bible. It measures 8 by 9½ inches, by 1½ inches thick, and weighs 4 pounds. It is printed on very heavy toned paper, with heavy gilt edges; is bound in light-blue cloth, embossed in black and gold; contains 512 pages and 312 original illustrations. The subject-matter is a series of fables and allegories, each giving a most wholesome moral lesson that very few of us, old or young, do not need. This book would be an ornament on the center-table in any home; and if read and pondered, and its lessons put into practice, many hearts would become more lovely, and many homes more pleasant and beautiful. The lessons taught are made much more pungent by the pictures accompanying, as in many cases the story is more than half told in the pictures. So large and nice-looking a book is rarely sold by agents for less than \$4.00. Our price is \$1.50. By mail 32cts. extra, or given for 6 subscriptions, with \$6.00, and 32 cts. to pay postage, if sent by mail.

BIBLE PICTURES, and What They Teach Us. This is a very handsome book by the same author, Charles Foster. It contains 315 large illustrations from the Old and New Testaments, with brief descriptions. It contains 232 pages, 8x10, with embossed cloth cover, title in gilt, printed on heavy paper. The book weighs 2½ lbs., and takes 20 cents to mail it. It will make an excellent Christmas or birthday present for a child. It is written chiefly to instruct the children, and should be in every home. Regular agent's price, \$1.50. Our price, \$1.00. By mail, 20 cents extra, or given free for two new names and your own renewal for GLEANINGS, with \$3.00, and 20 cents to pay postage, if sent by mail.

FIRST STEPS FOR LITTLE FEET. This is by the same author, and is a collection of simple Bible stories intended more especially for younger learners. Every child should have one of these to read; 328 pages, and 140 illustrations. Very nicely printed, and bound in cloth, title in gilt. Price 50 cents each; 2 for 75 cts. Given free postpaid for 2 subscriptions.

THE CHRISTIAN'S SECRET OF A HAPPY LIFE. This book should be in the hands of every one who desires to live a happy life, and who does not? It is so popular that over 50,000 have been sold since its publication a few years ago. We received from the publishers as many as 1250 in one shipment. This edition was revised and enlarged, so that the book now contains over 200 pages. Price, cloth bound, 50 cts. In paper, 25 cents. Postage extra, 8 cents for the cloth and 6 cents for paper bound. The cloth book given postpaid for 2 subscriptions, or the paper for one new subscription.

EVERY DAY RELIGION. This is a later work by the author of The Christian's Secret of a Happy Life. Many of our readers are familiar with that work, we having sold upward of two thousand of them. This later work will be appreciated fully as much. The secondary title is, The Common-Sense Teaching of the Bible. It is a most practical work which should be read by every earnest Christian. It is in cloth covers, has 250 pages, and will be sent postpaid for 90c; regular price \$1.00. With other goods by express or freight, at 85c. Given free postpaid for 2 new subscribers to GLEANINGS with your own renewal and \$3.00.

TOBACCO MANUAL. By N. A. Hunt. This is a book of 192 pages, cloth bound, containing information concerning the tobacco habit. It ought to be in the hands of every one, as an educator. Tobacco-users should read it, to show them their foolishness and filthiness. Those who do not use the noxious weed should read it to arm themselves for the anti-tobacco fight. Price 45 cents; postage, 5 cents extra. Given free postpaid for one new name and one renewal.

A B C of Bee Culture.

It is hardly necessary to speak of the merits of this work, which, judged from its extensive sale, is the most widely read book on bee culture in the English language, and, for aught we know, in any language. The last edition completes 62,000 copies from the press during the last eighteen years since it was first printed. This last edition has been greatly improved. It is enlarged to 475 octavo pages, with over 300 illustrations, many of them full page. Some of the latter embrace a view of the apiaries of some of the largest and most successful bee-men. In the back part of the work is a biographical department of sketches and half-tone portraits of the most successful American apiarists. The whole work is brimful of contagious enthusiasm, and the style simple and instructive. None of the matter pertaining to the apicultural part of the book is electrolytized, but all is kept in standing type, so that when any new thing of importance comes up it can be inserted in its proper place, and the old struck out. Its quicksales have warranted us in giving it frequent and thorough revisions. The present edition is greatly enlarged and improved, so that it is nearly twice the size of the one first issued; and no bee-keeper having one of the earliest copies can afford to be without this latest edition. The book has grown so large that it now takes 19 cents postage to mail it. We have not changed our prices, however. Price \$1.25 postpaid; \$1.10 with other goods. GLEANINGS one year, clubbed with the A B C, postpaid for \$2.00. If you send three new subscriptions with your own renewal and \$4.00, you may have the book postpaid; or if you send two new subscribers with your renewal and \$3.30 you can have the book prepaid.

OLD EDITION.—We still have a few copies of the old edition which we offer, as long as they last, at \$1.50 for the book, and GLEANINGS one year, paid in advance, or for one new subscriber, sent with your renewal and 15c for postage, we will send a book free. A few in paper covers will be sent with your renewal at \$1.35, or postpaid for one new subscriber with your renewal and \$2.00.

Bees and Honey. in cloth, by Thos. G. Newman. We have a good supply of this work, which sells regularly at \$1.00, postpaid, which we offer along with GLEANINGS one year for \$1.50, postpaid, or we will give one copy free for one new subscription with your own renewal.

Bienen Kultur. This is a condensed edition of the same work in German, and paper covers. Price 40 cents, postpaid. We will send this free, postpaid, for one new subscriber, or with a renewal for 10 cents additional.

Dzierzon Theory. This is a little pamphlet of 48 pages, valuable to every bee-keeper. Will send one free, postpaid, for one renewal and your own renewal if sent before your paid subscription expires.

Any of the following books sent free postpaid for one new subscription with your renewal and \$2.00.

The A B C of Potato Culture.

Paper, 220 pages, 4x5, illustrated. This is T. B. Terry's first and most masterly work. The book has had a large sale, and has been reprinted in foreign languages. The second edition, reset and almost entirely rewritten, is just issued.

When we are thoroughly conversant with friend Terry's system of raising potatoes, we shall be ready to handle almost any farm crop successfully. Price 40c, postpaid.

The A B C of Strawberry Culture.

Paper, 150 pages, fully illustrated. This is Terry's latest small book, and has received some very high words of praise. Who among rural people does not have a little garden-plot? If you would learn to raise in it that most luscious of all fruit, the strawberry, with the best results, you

can not be without this little book. Even if you don't grow strawberries you will be the better for reading it.

Maple Sugar and the Sugar-Bush.

By A. J. Cook. Paper, 44 pages, 7x10, illustrated. This is most valuable to all who are interested in the product of our sugar maples. No one who makes maple sugar or syrup should be without it. If you don't make maple syrup you may want to know how it is made, and how to judge of a good article when you buy it. Price 40c, postpaid.

Tomato Culture.

In three parts. By J. W. Day, D. Cummins, and A. I. Root. Paper, 150 pages, illustrated. A most valuable treatise embracing field culture, forcing under glass, and raising plants for market. Valuable to any one raising garden stuff of any kind, aside from tomatoes. Price 40c, postpaid.

A B C of Carp Culture.

In paper covers, illustrated. This is a work of 70 pages, 7x10, written by Geo. Finley and A. I. Root, and the best authority on the subject of carp culture yet in print. The rearing of carp is a pleasant and profitable amusement. This book will tell you all about it. Price 40c.

Winter Care of Horses and Cattle.

This is friend Terry's second book in regard to farm matters; but it is so intimately connected with his potato book that it reads almost like a sequel to it. If you have only a horse or a cow, I think it will pay you to invest in the book. It has 44 pages, 7x10, illustrated. Price 40c, postpaid.

Tile Drainage.

By W. I. Chamberlain. This is a valuable companion to our other rural books. It embraces the experience of forty years of one of our foremost practical agriculturists, who has laid with his own hands over 15 miles of tile. Paper, 150 pages, illustrated. Price 40c, postpaid.

Our Farming,

by T. B. Terry. This will be a most helpful book for any farmer to read. It is a large work which sells for \$2.00, postpaid. We offer it with GLEANINGS one year for \$2.50. For one new subscription, with your renewal and \$1.00 extra, or \$3.00 in all, you may have the book postpaid.

Merrybanks and His Neighbor.

By A. I. Root. This is the title of a little book of 210 pages and 68 illustrations. It narrates the alternate failure and success of a beginner who ultimately, through much tribulation, becomes a successful bee-man and a power for good in Onionville. Appropriate original cuts, many of them humorous, are interspersed here and there, representing some of the droll experiences which a beginner with bees sometimes passes through. Besides bees, it talks of other rural pursuits, such as gardening, maple-sugar making, etc. It has a good deal to say about our homes, and more particularly one home which was started upon a sandy foundation, but eventually became builded upon the Rock Christ Jesus. The book is full of instruction; price 25 cents; 3 cents extra when sent by mail. Given free for one renewal, and 5 cents to pay postage and mailing.

What to Do, and How to Be Happy

While Doing It. This is a book of 190 octavo pages same size as this, and 80 illustrations, written by A. I. Root, especially helpful to those out of employment or to those who have a hard time in making both ends meet. How to find something to do right at home instead of going to the already too-crowded cities. How to be your own boss and enjoy your work. The true secret of real enjoyment in work. This book will well repay a careful reading. Price, in paper covers, 50 cents, postpaid; 45 cents with other goods. Given free, postpaid, for a new subscription with your own renewal. In cloth covers, 25 cents extra; or given free for one extra subscription.

FROM ANOTHER POINT OF VIEW.

I see that Old Durham rushes into print to air his views on the fence question. He seems to be perfectly **cowed by elasticity**. I think that Page fence a saucy, impudent thing, always **answering back** in the most aggravating manner. Then you never know just where to find it. Now that "just as good as Page" suits me. It never "kicks" at anything, and if it's absolutely necessary to go through it, one can do it, so there!

[Signed.] OLD BRINDLE COW.

In writing advertisers please mention this paper.

The New Corneil Smoker.

BOTTOM

Cheap,
Strong,
Serviceable,
Large Size.

JUST THE THING for those who want a first-class smoker at a medium price. Size of cup, 3½ inches; curved nozzle, hinged so as to swing back; legs of malleable iron, secured by bolts. The blast is the well-known Corneil principle. Weight of smoker, only 20 ounces. Here is what one of our customers says of it:

The Corneil smoker is a Dandy with a big D. I have been using it to-day on the crossbred colony of bees I ever saw. I think I could drive a bulldog with it. S. R. ARSTEN.
Amityville, N. Y., Oct. 15.

Price \$1.10, postpaid, or 85c if sent by express or freight with other goods.

**THE A. I. ROOT COMPANY,
MEDINA, OHIO.**

Bicycles

I have done an extensive business in bicycles this summer, and have now on hand a number of second-hand bicycles, taken in trade or used as samples. Either these or new bicycles I will sell for the lowest cash prices, or will take honey or beeswax in exchange. Send for list.

J. A. GREEN, Ottawa, Ill.

Headquarters in Missouri For Root's Goods.

Can supply you with all the fixtures used in an apiary. Best goods at lowest prices. Catalog free.

JNO. NEBEL & SON, High Hill, Mo.

MUTH'S HONEY-EXTRACTOR, SQUARE GLASS HONEY-JARS.

Bee-keepers' Supplies in general, etc., etc. Send for our new catalog. "Practical Hints" will be mailed for 10c in stamps. Apply to

Wants or Exchange Department.

WANTED.—To exchange 26-in. planer, power scroll saw, all iron; tenoner, and mortiser, for portable sawmill, or other wood-working machinery. Will give a bargain for cash.

edit GEO. RALL, Frenchville, Tremp. Co., Wis.

WANTED.—To exchange foundation-mills and honey-extractors for honey or wax.

I. J. STRINGHAM, 105 Park Place, New York.

WANTED—To exchange 200 colonies of bees for anything useful on plantation.

ANTHONY OPP, Helena, Ark.

WANTED.—To exchange safety bicycles, Barnes No. 4½ lathe for metal work, Odell typewriter, for honey, beeswax, or gasoline or kerosene engine.

J. A. GREEN, Ottawa, Ill.

WANTED.—To exchange, for honey or offers, one saw-bale and mandrel, chain-gauge, two 10-inch and three 6-inch saws, and one Noxal brooder for 200 chicks.

J. T. VAN PETTEN, Linn, Kansas.

WANTED—To exchange peach-trees, any or all the best varieties at 4c each, and Abundance, Burbank, and Satsuma plum-trees at 10c each, for bees. The trees to be shipped to you by freight or express in April, and the bees to be shipped to me by express in May or June. You to pay express charges on bees. Make proposition for one hive or more, and if we agree on a trade I will book your order for the trees and send them in April. In 1889 my apiary was in the city of Madison. There foul brood came. In 1890 I moved 50 colonies to this farm. In 1895, spring come, I had nary live bee. I want to make a fresh start.

JOHN CADWALLADER,

Cedar Grove Farm, North Madison, Indiana.

BEGINNERS.

Beginners should have a copy of the Amateur Bee-keeper, a 70-page book by Prof. J. W. Rouse. Price 25 cents; if sent by mail, 28c. The little book and the Progressive Bee-keeper (a live progressive 28-page monthly journal) one year, 65c. Address any first-class dealer, or

LEAHY MFG. CO., HIGGINSVILLE, MO.

CLOSING OUT!

Select tested Italian queens at \$1.00 each; tested, 75 cts.; warranted, 50 cts. Safe arrival and satisfaction guaranteed.

Golden's Feeder.✠✠✠

We can furnish the Golden combined feeder and hive-cover direct from the factory, as follows; without feed-dish, as any dish, such as Simplicity, answers: 1. made up, 30 cts.; 1. in the flat, 25 cts.; 10. in the flat, \$2.00. Send all orders to the A. I. Root Co., Medina, O. For large orders write the undersigned for special prices.

J. A. Golden, Reinersville, O.

In writing to advertisers please mention this paper.

Winter Losses

etc., etc. Successful wintering comes from a proper combination of different conditions. For clear, concise, comprehensive conclusions upon these all-important points, consult "Advanced Bee Culture." Five of its thirty-two chapters treat as many different phases of the wintering problem. Price of the book, 50 cts. The Review one year and the book for \$1.25. New subscribers get balance of this year free. I can still furnish queens by return mail at \$1.00 each, or \$5.00 for six. One queen and the Review for \$1.50. Queen and book, \$1.25. Queen, Review, and book, \$2.00.

W. Z. HUTCHINSON, Flint, Michigan.

Don't Miss This Big Offer!

IT STILL HOLDS GOOD.

A Full Report of the Proceedings of the North American convention held at Toronto, Canada, will appear in the *weekly* American Bee Journal immediately after the meeting, Sept. 4, 5, and 6. The first installment will be in the number for Sept. 19. If not now a subscriber, you can have that Report free by sending \$1.00 now for the American Bee Journal for 1896, as we will "throw in" the balance of the year 1895, beginning with Sept. 19, to new subscribers. Think of it! over 15 months (or nearly 70 numbers) of the old American Bee Journal for only \$1.00! Sample copy of Bee Journal free.

And, besides all that, each new subscriber will receive a free copy of the 160-page book, "Bees and Honey." Better send on your dollar at once, and join the procession. Mention this paper, please.

Proof Beyond Doubt.

A customer, looking over my 400 hives in home apiary, said, "Where are your bees? Mine were flying all around thick this morning." I said, "Just stop; look down at any hive." He was amazed. They were just pouring in thick with their heavy loads. This proves two things—they can't be excelled as workers, and quiet.

I opened several hives. He had no veil; was in the apiary 1/2 of an hour; was not bothered once. Try them. Untested guaranteed queens, 75c. Send for wholesale price list.

Vol. XXIII.

NOV. 15, 1895.

No. 22.

STRAY STRAWS FROM DR. C. C. MILLER.

I'M RIGHT GLAD A. I. Root is on the sick-list.

VOGEL scouts the idea of crossing *Apis dorsata* with the common bee. [Who said they could be?—ED.]

WEYGANDT finds that virgin queens are fertilized sooner if taken to a distant apiary than if left at their own home.

THANKS to Bro. Poppleton for light given, p. 807. He encourages me to think that my scheme outlined on p. 740 may possibly work all right.

IN ENGLAND they have been having trouble in some law cases to decide whether or not beeswax is a drug. Not much of a "drug on the market," anyhow.

WILL A YOUNG QUEEN make her bridal excursion so long as unsealed brood is present? Gravenhorst says he has never known it to occur except in a single instance.

THE BEE CLOVER that I asked about Sept. 15, L. P. Cousins writes he has grown for years. "When once seeded it will seed itself like caraway; will scent your whole garden."

RAPID FEEDING. The slower this can be done the better, provided there is time. I find from experience that rapidly fed stocks are generally weak in the spring.—*Apiarist* in B. B. J.

THE GREAT VARIATION in the weight of bees given on p. 800—from 3000 to 10,200—will be better understood when it is mentioned that the 10,200 bees in a pound were brought to the starving-point.

I SAID I WAS GLAD A. I. Root was on the sick-list—not that I wish him harm, but he's hunting up some useful things that the rest of us can have the benefit of; and if he'd stayed well and strong he never would have thought of them.

L. P. COUSINS writes that he has wood-base foundation in a number of hives, and the combs are as fine as could be desired. One's sympathies are aroused for the family of the inventor, who is now hopelessly insane.

MY LITTLE PATCH of crimson clover looks quite green the first of November. Sown with oats in spring it bloomed pretty well, and I supposed would be dead long ago; but I don't expect it to stand the winter.

HASTY says in *Review* that "a hive needs a visible number on it no more than a toad needs a tail." Which makes me think, in view of the confidence I put in Bro. Hasty's judgment, that I may have underestimated a toad's need of a tail.

A STRAW on page 800 says, "I have thousands of sections filled with foundation." Certainly not a remarkable statement, but please add to it something like this: "three or more years old that I expect the bees to accept all right next year."

I DON'T KNOW about that opinion "that the beginner had better commence with the small hive." Too much danger he'll let his bees starve, unless, indeed, he uses the small, hive two stories. [I don't know—I don't know but you are right.—ED.]

I FIND some excellent hymn tunes written by E. E. Hasty—same name as the one who writes such wonderfully bright reviews in *Review*. I suppose it's the same man. [That Hasty is an all-around genius, and a lover of the really beautiful in life.—ED.]

GRAVENHORST says you could not make a worse mistake than to try to winter on combs entirely filled from top to bottom with sealed honey. [It would be bad policy; but there are, in my estimation, many worse things that could be done.—ED.]

IN REPLY to my question, "What constitutes too large a colony?" friend Hand says, p. 809, "Too many bees." That throws a flood of light upon the question. Now will he kindly tell us how many he thinks "too many"? [We will leave friend Hand to answer.—ED.]

IN GERMANY the Koehler plan has been practiced with some success in controlling fertilization. Put the queen with the selected drones in a nucleus, keeping them in the cellar all day, and let them fly after 5 o'clock. Repeat daily till successful.

CRIMSON CLOVER, says a writer in *B. B. J.*, is only now getting in America the reputation it has long had in England as a honey-plant; but he says they've also found out its honey is by no means first-rate. [I suspect it will do better in England because the climate is milder than here.—Ed.]

S. JORDAN relates in *B. B. J.*, that, after transplanting pyrethrum-plants, he attempted to handle his bees, but they came at him in such shape that he "hastened" from the field. He washed his hands and returned to the bees, and the viragoes of three minutes before were now gentle as sucking doves.

THINKING OVER friend Hatch's answer, p. 810, I'm inclined to think the $\frac{1}{2}$ -inch space between the two stories may have had something to do with his queens not going up and down. My bees went up and down all right this year, with about the same conditions, only mine had only $\frac{1}{4}$ -inch space to cross. [Yes, there is the difference.—Ed.]

LOOKS A LITTLE as though A. I. Root was to have a rival in B. Taylor as a high-pressure gardener. Bro. Taylor says in *Review* that his honey crop is a failure, but he has a bountiful crop of almost every thing on a half-acre of land. Some fair crops on my land this year, too, but I didn't raise them. Nor a crop of honey either.

FOUNDATION-FASTENERS, says C. W. Dayton in *Review*, instead of having the melted wax run to the rear end of the plate and drop off, should have it run to the front edge and drop off on the section. The extra melted wax would fasten the starter more firmly, but in some cases it might cool too slowly. The present fasteners make pretty solid work though.

B. TAYLOR reports in *Review* that he made 250 sheets of foundation without side walls—sheets thin, and rolled so as just to shape the cell-bottom—and put in wired frames; they made model combs of straightness and beauty. [Don't doubt it; but it was a waste of wax. Foundation with *good side walls* and a *thin base* is much cheaper per square foot, and is just as good.—Ed.]

I'M NOT MUCH of a novel-reader; but when I got hold of the new book, "How to Get Well and Keep Well," I acted like one, for I just let all my work go and read it right through without stopping. If you want to know all about the Salisbury treatment, by all means get the book. Whether you care for the treatment or not, you'll get some excellent ideas from the book.

MRS. EDITH MILLER, editor of the *Kansas Bee Journal*, is a clipper. At any rate she makes good work clipping paragraphs from the bee-journals and massing them under the title, "What Others say." [Yes, indeed, Mrs. Miller is a success as a clipper of good things. There are other good things in her paper besides, although it is only a youngster.—Ed.]

THE EDITOR of the *American Bee-keeper*, after attending the Toronto convention, says, "Any one can find fully as much to interest him in almost any single copy of any of the bee-papers as was heard during the entire convention." Pretty poor convention that, measured by some of the bee-papers. [The editor of the *A. B. K.* has not been at bee conventions enough, or kept bees enough to form a proper opinion, I suspect.—Ed.]

YORK AND HUTCHINSON are favoring a trial of having the North American meet at the same time and place as the G. A. R. That would make low rates sure, and we can stand almost any inconvenience if we can only have railroad rates low enough. [I am with York and Hutchinson. In order to get any kind of attendance we must have it held where low rates will be secured independent of the bee convention. This $1\frac{1}{2}$ -fare business, as Hutchinson says, amounts to nothing.—Ed.]

GERMANS are sometimes prodigal of words, but in one case at least they are more economical than we. Instead of saying a plant "yields honey," they just say the plant "honey." I wish we had such a verb. [Bee-keepers, or, rather, editors of bee-papers, might do much at simplifying our nomenclature, without offending good taste or obscuring the meaning. For instance, Langstroth recommends the words "queen" and "unqueen" as verbs; and S. T. Pettit would use "floor" instead of bottom-board, and "bar" instead of perforated metal. GLEANINGS will be glad to assist.—Ed.]

THE SUBSCRIBERS of GLEANINGS are fewer than I supposed, if each one can have a pound of potatoes out of that five barrels—see p. 819. [Look here, doctor, I did not say that every subscriber to GLEANINGS could have a pound of potatoes out of that five-barrel lot. Didn't I say in plain English, "If you do not want to take the trouble to get a subscriber to GLEANINGS, make some of your friends, who you think would be interested in it, a present of it for one year, and we will send you the pound of potatoes"? My offer was made in order that we might get GLEANINGS introduced into families or neighborhoods where it has never been before. Of course, the one who sends us a new name must be a subscriber to GLEANINGS himself. Then I added, if it was too much trouble to hunt up a new name, make somebody a present of it. Very likely I did not make it as plain as I might have done, but I think you

will understand it now. One friend sends us \$10.00 (for 10 lbs. of potatoes), with two new names, and says for the other *six*, "Send me GLEANINGS six years." Oh dear me! I was afraid all the while I should get into a muddle. Now I will tell you: if any of you want to subscribe away ahead we will put it this way: You will want to take GLEANINGS for 1896, most of you, any way—at least I hope so. So we will call that settled. But if you can not get a new subscriber anywhere around you, then just send us \$2.00—half of it for 1896 and the rest for 1897—and we will mail you the pound of potatoes, and you need not do any hunting. By the way, doctor, if I had my way about it I would tell just how many subscribers to GLEANINGS we do have, every issue. But some of the younger Roots think it is not customary, and perhaps not exactly business-like. I will tell *you*, however, in strict confidence, because you are an old friend, that we have somewhere between 9000 and 10,000 paid-up subscribers just now.—A. I. R.]

CALIFORNIA ECHOES.

By Rambler.

Dr. Miller is such a musical man that it seems "Stray Straws" is a misnomer. How would it do, doctor, to change the name to "A Harp of a Thousand Strings"?

Mr. Dosch, on page 737, describes just the way I used to feel after a disastrous wintering of bees in York State. Remedy, pull up stakes, and pull for the bee-keeper's refuge, California.

Later.—If Mr. Dosch lets his neighbor Shaw (see page 770) get so far ahead of him, with only three intervening miles, Dosch had better stop in Arizona.

On page 739 Dr. Miller brings out the idea that lifting heavy hives is a work that some people can not do. I found a case here a few days ago where a threescore-and-ten bee-keeper of feeble frame had shortened his L. hives several inches in order to bring them within his lifting powers. A jumbo hive may be the thing, but it must be a permanent institution, like a house or a barn.

Did you notice what Prof. Verlinden said on page 737, about churning honey? That's just the trick I tried several years ago. I used a quart fruit-jar, and operated the dasher by a slack pulley on a belt from an engine. I could keep the churn going all day. I think it did hasten granulation; but, professor, we want a machine to *prevent* granulation. Can you help us?

A little further along Prof. V. says of a bee-keeping specialist, "He buys much honey of strangers which he *manipulates* before he sends it to its destination." Well, well! with what *sang froid* he says it too! Tell a bee-keeper in

this country that he *manipulates* his honey, there'd be a little dust, a little blood, bruised hat, torn coat, and the best man on top.

Mr. D. A. Wheeler, of Riverside, who owns about 1000 colonies of bees, and has produced about 55 tons of honey during the past season, soon leaves for Chicago, where he will establish a house for the sale of California honey. Mr. Wheeler proposes to pay cash for all of the honey he handles for other parties. The present ruling price here is 3 to 3½ cents for extracted honey, and 8 to 9½ for comb, and but little demand at those figures.

It seems that we want *Apis dorsata*, and then we don't want her. Now I have a plan. When Uncle Sam gets ready to send me rambling after Miss Dorsey I'll sail right off into the Pacific Ocean till the bee is caught, then plant a few colonies on the Sandwich Islands, to see how they stand "furrin" parts. If they are desirable for the islands, of course they would be for California, and could be wafted to our shores. No patent on the fore-going, and the route is open to all contestants.

PICKINGS BY THE WAY.—NO. 1.

By Skylark.

INTRODUCTION.

Some people here call me the "literary giant," and others an "idiotic giant." Besides, there are still others who say I have the "big head." The two latter classes have a large majority. The term "giant" refers entirely to the large amount of undeveloped intellect stored away in my mind, and not at all to my person, which is not over ordinary size, and very *elite* and distinguished. When one aspires to high literary honors, the public wants to know who he is and whence he came. I sent my brother to the Mexican war, and he whipped the Mexicans. My father was in the war of 1812, and whipped Great Britain. My grandfather *would* have whipped the Tripolitans in 1804 if he and two other lieutenants had not voluntarily "blown themselves up." They took a fire-ship into the harbor of Tripoli, loaded with 100 barrels of powder, to blow up and burn the enemy's shipping. Being discovered and overpowered they voluntarily set fire to the powder and blew their enemies and themselves into the air. Congress passed a resolution of sympathy for the families of these "noble men," and advised all their noble descendants to follow their example.

Now, I love my country. I love the old flag, and I love Congress, and I want to obey it. Do you, Mr. Editor, know any easy way that a man could blow himself up and not get hurt? The only way I can think of is to go to war in GLEANINGS, and I shall be blowed up often enough, I suppose, and Congress will be satisfied.

Did you ever see a mule try to kick himself to death with the agility, perseverance, and self-determination that Bro. Dayton evinces on page 729? He is actually trying to do that very thing. I do not intend to reflect on his moral character. The mule is a gentle, docile, patient, and useful animal—when he is good. But with all these excellent traits he is not to be depended on as a bosom friend. I say this with deep regret, for I once had a mule that I slept with—about forty yards off. Neither do I intend to reflect on his (brother Dayton's, I mean) intellectual abilities. He may have an intellect *almost* as stupendous as my own, but—but I have my doubts.

I only wish to illustrate the eagerness with which he rushes on to self-destruction. When a professional bee-keeper asserts "that half the honey that leaves this coast is adulterated with glucose," can he blame outsiders for taking up and echoing the cry? This is the wildest assertion I have seen in any bee-paper for a long time. It is not only *not true*, but, at the present price of extracted honey here, it is absolutely ridiculous.

Glucose is not produced on this coast. It must be brought from the Missouri River. It could not be made here with profit, where corn meal is retailed at $2\frac{1}{2}$ cents per pound. I suppose glucose would cost 2 cents per pound; freight overland, $1\frac{1}{2}$ cents; drayage at both ends of the line, handling, and mixing, at least $\frac{1}{2}$ cent more. Then each 120 pounds of glucose would take a new case and cans—say 80 cents more. This would run the cost up to $4\frac{1}{4}$ cents, while pure honey could be shipped at $3\frac{1}{2}$ cents. Even if glucose could be bought for *one* cent a pound, the mixture would still cost as much as pure honey. More than two million pounds of extracted honey have been sold on this coast this year for $3\frac{1}{2}$ cents; and even now they are offering only $3\frac{1}{4}$. No large house could stand up under such transactions as friend Dayton describes. No house of that kind would last more than one year. Moreover, it would not be a financial success unless they would *steal* the glucose. I know they have not done that. I am sure of it. I am known in San Francisco to be the most successful remover of large quantities of goods, when the owner is not there, that there is on the Pacific slope. None of the large honey-shippers have made application for my services.

I do not believe that one case of honey in 20,000 that leaves this coast is adulterated. No double-gear'd idiot, standing on his head, would think of it. Really, I believe the man wants to blow himself up. Look here, Bro. Dayton, don't you do it. I am the only man in all these United States who has the authority of Congress to blow himself up for the good of his country and his fellow-men. Don't you do it. I don't want to see you shot, imprisoned,

fined, and hung! Look at the awful prospect before you. Look at the court, the crowd, the scaffold, and the grave!

The latter part of Bro. Dayton's letter is an absolute wail of agony against the retail grocer for selling sugar too low and honey too high—against the Speckles monopoly, the county supervisors, town councils, merchants, adulterators, etc. Bro. Dayton, if you survive the catastrophe I have indicated above, why not get aboard of a Kansas cyclone and run the whole "bilen" of them down?

RAMBLE 143.

By Rambler.

On the 6th of December we entered the tail end of the Sanfrancisketo Canyon, and our ponies put us many miles toward home, for we were on the down grade all day. Mountains hemmed us in; wild scenery; side canyons, rugged cliffs; winding glades, and finally a nice stream of water, a branch of the Santa Clara River.

This is a good honey-producing canyon, and we often caught a sort of panoramic view of an apiary as we whirled along. They were not in a high state of order; things were tumbled around as though a brace of bears might have been turned loose among the hives.

The locality is certainly wild enough and lonely enough to suit the most hermit-disposed bachelor.

The last apiary we passed, we learned afterward, was owned by Mr. Mercer, of Ventura. The wind could whistle through every thing on the plantation, and we noted that the honey-house was well ventilated. The view from the highway was highly satisfactory to our curiosity, and we kept right on our way, and camped that night under the broad-spreading oaks just out of the town of Newhall.

The rains descended that night; the wind blew; the thunder rolled, and we had a hard time keeping our tent from going over the trees. Our sleep was of the restless order, and we were happy to see the morning break, with prospects of fair weather. Just six months before we had crossed the San Fernando Pass, and it was then arduous climbing; but now, after the heavy rain of the night, we feared rough roads, and we were not disappointed. Our wagon swayed through wash-outs and over debris; and we had gotten well down the other side, and were congratulating ourselves that the worst was passed, when we came to a little stream of water running quietly across the

MOSES R. CHANDLER'S FRUIT-RANCH AND APIARY, SAN FERNANDO APIARY, CAL.

road. It had been a torrent during the night, and had left quite a space of soft mud or quicksand in the road. The ponies plunged into and through the mud. Our wagon reached the center, and the mud and quicksand closed around the wheels, and we were firmly locked against further progress. Progress was our watchword, and the whip was applied to the ponies for a desperate pull. Result, a broken whiffletree. Our progress was from bad to worse.

Just at this moment a traveling emigrant family, with a prairie-schooner outfit, came up to us. They kindly loaned us a shovel and ax. Wilder cut a big lever, and I shoveled and he pried. As fast as I could take out a shovelful, another shovelful of soft quicksand would take its place. We spent some time in this delightful exercise, with our feet in mud and water, without satisfactory results.

Then it commenced to rain—a real smart mountain shower; it pelted us thoroughly: the water zigzagged down our spinal columns, and everybody, even the horses, looked and felt their unlimited disgust.

But, wait! It rained enough to send a little stream of water down the road behind our wagon. It runs parallel to the right-side wheels of the wagon, and, as sure as you live, it is washing the quicksand and mud away from them. Quick now! With the shovel we divide the little stream and run half of it to the other wheels, and in a few minutes the wheels are all washed free. The shower passes; the ponies are attached to the end of the pole, and out goes our wagon with a rush. A bailing-wire mends our whiffletree, and, after an hour's vexatious delay, we are able to proceed upon our journey. The shower feature of our mishap, which we looked upon with such disgust, proved to be our best friend. Parties afterward told us that we were very fortunate to have the shower, for in like mishaps they were obliged to take their wagons apart and dig the wheels out with a pick.

Moral.—In this journey of life, many times what we consider misfortunes are our best friends. So let us learn to be cheerful, not repining under any circumstances, however dark and forbidding they may appear.

Sweet are the uses of adversity,
Which, like the toad, ugly and venomous,
Wears yet a precious jewel in his head.

That night, after a long and forced drive, we halted at the residence of Moses K. Chandler, at Dundee, 13 miles from Los Angeles. We rejoiced that we were now over all of the mountain ranges, passes, and canyons, and under the roof of a hospitable bee-keeper. We had been in wet clothing all day, and we made good use of the kitchen stove, for getting rid of surplus moisture,

Mr. Chandler has a pleasant home, as shown in the accompanying half-tone. It is close into the foot-hills that border the San Fernando Valley. Fruits of many varieties, both great and small, are successfully grown, and 130 colonies of bees help to swell the revenues of the ranch. This is one of those ideal locations I love to find—a location where the bee-keeper and his family have a permanent residence near the apiary. Mr. Chandler gets excellent yields from his apiary; and, living so near the great and prosperous city of Los Angeles, and, furthermore, being somewhat of a salesman, he finds a ready and remunerative market for his ranch products—green fruits, dried fruits, nut-, honey, and an occasional load of vegetables.

The reader will observe through the photo that the ranch has a prosperous appearance; but at this writing, some months after the

CHANDLER'S HELPER.

photo was taken, Mr. C. has prospered so much that he is building a fine modern residence upon the site of the little white cabin. Mr. C. has an efficient helpmeet in the house, who keeps things well in hand for whatever business may come along. A young lady is stopping in the family, who has taken up the manufacture of tin cans for honey. She first made the cans for Mr. C.'s honey crop, and succeeded so well in wielding the soldering-iron that scores of cans were turned out for the neighboring bee-keepers, and the miss does not aspire to be what is called a "new woman" either.

Another very faithful helper on the ranch is Chinaman Hop Lee. He has been with Mr. Chandler for several years. A few years ago, when there was much excitement in this State in relation to the employment of Chinese, a notice was served upon Mr. Chandler, commanding him to discharge the Chinaman. Now,

Mr. C. was born among the cloud-capped granite hills of old New Hampshire, and he did not propose to turn off one foreigner at the command of other foreigners, and had the independence to say so. Things looked a little squally for a while, and Hop trembled in his brogans; but Mr. C. stood firmly by his word, and the Chinaman Hop still eats rice with chop-sticks in the little cabin shown in the photo, between the apiary and the residence.

In an interview with Hop in relation to bee-stings he said, "Him blee heep stling; heep stling Mr. Chandler; heep stling horseshes; me no like him; me slay in tluhn honey-extractor; get heep honey; pleek thro wire windlo; slee Mr. Chandler get stlung; me ha-ha; him slap his hands; him no swear like some Melican men. Mr. Chandler heep glood man; me no swear too. Me feel heep comfble in honey-house."

We camped over Sunday with Mr. Chandler, and found them to be good Salvation Army people. The daughter, holding the position of lieutenant, is earnestly holding out the rescuing hand in the various places to which she is assigned in Southern California.

Early Monday forenoon we turned into the San Gabriel Valley, and saw in the distance the snow-capped peaks of the San Bernardino range of mountains. Our ponies here caught some enthusiasm. They evidently knew the landmarks, and put in a good day's travel on the home stretch, and in the early evening of the 11th of December we arrived at the residence of our friend and near neighbor, Mr. Clark, and considered our journey at an end.

For six months our home had been, in every sense of the word, migratory. New scenes and experiences had been our pleasure from day to day; and even after six months of it we were loth to return to the quiet every-day duties of every-day life.

When we repaired to our respective bachelor's cabins we were for a time oppressed with a sense of dullness. During the many rainy days that followed we felt decidedly more comfortable under a shingle roof than we did under the dripping tent roof. Then the raindrops brought consoling thoughts of big honey-yields for the coming season.

No man is born into the world whose work
Is not born with him; there is always work.
And tools to work withal, for those who will;
And blessed are the horny hands of toil.

Our work is to produce honey. Our tools are the busy bees and the hives. In preparing them for the prospective good season, dullness soon left our cabins, and the imagined pleasures of producing tons of honey took possession of us.

Though our work did not produce the horny hands, it was blessed with good results, the account of which will appear later.

THE NORTH AMERICAN AND THE UNION.

SHALL WE HAVE LARGE MEMBERSHIP AND SMALL FEE, OR SMALL MEMBERSHIP AND LARGE FEE? WHY WE SHOULD HAVE THE FORMER.

By Dr. C. C. Miller.

I'm looking for good to result from the action at Toronto with regard to the North American and the Bee-keepers' Union. Rev. W. F. Clarke is right in saying the North American has always been local—at least nearly right—and it always will be mainly a local affair just so long as it is so managed that only those who attend have any inducement to become members. So far the effort has been to secure attendance, not membership. That must be entirely changed if it is ever to be any thing more than a local affair. When comparing the membership of our societies with that of societies across the sea, it has been the custom to say that the great distances in our country preclude the possibility of having a large membership. That's all bosh. A man may be a member without attending; and if he doesn't attend, it's just as easy for him to become a member a thousand miles away as a hundred.

But I confess I don't understand Mr. Clarke when he says the North American has always been a "primary class of bee-keepers." I wish he would explain what he means. Is it the character of the men who have been in attendance, or is it the character of the discussions and deliberations that makes him classify it as he does? If the latter, what change would he recommend to make it "a high court or parliament of bee-keeping"?

MEMBERSHIP FEES.

At Toronto, Mr. Clarke said of the North American, "When we get down so that we have to pay only 25 cts. a year I don't want to belong to it." Why? I think both Mr. Clarke and myself have got down so we don't have to pay even 25 cents a year. Is that any reason we do not want to belong to it?

Mr. Newman thinks nothing will kill a society sooner than an insignificant membership fee. A small fee doesn't seem to have killed the many societies in foreign lands. What do we want of a fee larger than sufficient to pay expenses? He says, "The Bee-keepers' Union is respected, not because it has a membership of 300 or 400, but because it has a good bank account." Part of that is true. It is respected for its bank account, and that respect is neither increased nor diminished by the fact that the amount in bank came in large or small sums. But the intimation that numbers count for nothing is hardly correct. An organization of 1000 receives, as a rule, more consideration than one of 100. Now, suppose the membership is increased from 300 or 400 to 600 or 800, and the membership fee cut in two, leaving the bank account the same, will not the larger membership

with the same bank account have just a little more respect?

BUCKWHEAT HONEY VS. SUGAR, FOR WINTER.

A correspondent having extracted buckwheat honey from unfinished sections, and needing to feed for winter, wants to know whether it is better to feed the buckwheat honey or sugar. If I had the buckwheat honey in brood-combs all ready for use I'd use that for winter food rather than take the trouble of extracting and then feeding back. But if I had extracted buckwheat honey, with sugar as it now is in price, I'd sell the honey and feed sugar—all the more if the honey was extracted from unfinished sections, for in that case it would most likely be unfinished honey, and not the very best for winter stores.

A QUESTION OF MOVING.

The same correspondent is in a little doubt whether it is better or not to move his bees to a new location. Where he is in Pennsylvania, the lindens have been mostly cut off, and pasturage is getting scarce, except that some fifty acres of crimson clover have been sown within reach this summer. A location with which he is familiar in Virginia abounds in linden-trees that were loaded with bloom the past season.

Leaving out all questions except what is best for the bees, I think I'd take my chances on the Virginia territory. Linden rarely fails, and at its best is an immense yielder. Crimson clover is as yet an unknown quantity. Even if it be found that it will succeed perfectly in Pennsylvania, and if, too, it be found that it yields well, it will still be an uncertain quantity, for it must be sown annually; and whatever may be the amount sown this year, you've no guarantee that an acre will be sown next year, while your lindens are there as a fixture, and at the worst will be only gradually cleared away. Then, too, if the same amount of the crimson clover is sown every year, a large part of it may be plowed under as green manure; and of what use would that part of it be to the bees? The most reliable part will be that used for raising seed, and that is not likely to be large. I don't want to throw cold water upon the expectations as to crimson clover. I hope much from it; but when it comes to comparing chances between that and linden, with our present knowledge crimson clover is nowhere.

ROBBERS.

I had a little scrimmage with robbers this fall. It was at the time we were taking away from the bees in the home apiary all lower stories, some of the lower stories having considerable honey. A few frames, which we carelessly supposed to be entirely empty, but with a little honey in them, were left standing by a tree. When I first noticed the bees at work on them I thought it best to leave them, as there was only a little honey in them; and taking them away before the bees had emptied them and realized they were empty would only set the robbers at

work on the nearest hives. Whether these combs were directly to blame I don't know; but at any rate the next day I found lively times at No. 82 near by. I went and got some hay—not a few spears, but a whole armful—threw some loosely at the entrance, and then kept adding till the entrance and the entire hive was covered. Then I got buckets of water and thoroughly wet down the hay, and left the bees to their fate. I left the hay for a week; but there was no appearance of robbers shortly after the hay was put there. When I looked into the hive a week or so later I found a good colony there; but the robbers had emptied the three outside combs before they had been stopped. If they had not been meddled with I think the colony would have been ruined. No. 19, in the opposite row, was having a little trouble with robbers at the same time, but I didn't think it would amount to much. I didn't notice it till a week or two later, when I found it empty of honey, with the queen and a dozen bees. If I had given it a good feed of hay it might have been saved.

SWEET CLOVER HEAVED BY FROST.

On page 643 A. I. Root says of sweet clover, "It is never heaved out by the frost. So far as I am informed, the frost has never yet been able to budge a root of it after it had made one season's growth." I think you forget, friend Root, or else you overlooked a report that I made in GLEANINGS a few years ago. It will be easier for me to repeat it than to hunt it up and refer you to it; and, moreover, it may be worth more now than when first written, for I think more sweet clover is being now sown.

I had a piece of ground carefully prepared in the spring, the soil being made very mellow. It was sowed with oats, then with sweet clover. The sweet clover came up thick. The spring following I went with a good deal of interest to see what the sweet clover was like, and was very much surprised to find no living plants. I think there was not a single one. Plenty of dead plants were there, lifted bodily up by the roots. A point perhaps worth noticing was, that the plants were all small, not more than half the size that plants usually make in hard ground in the first year of their growth. So I conclude that adversity is good for sweet clover, and that the seed does best in hard ground.

Marengo, Ill.

[I think you have answered it yourself, friend M. The seeding was too heavy. A single plant of sweet clover on any kind of soil, no matter how poor, if there are not too many other sweet-clover plants all around it, will make such a growth, providing it has the whole season, that it is almost next to impossible for it to be heaved out by the frost. All along the ground beside the railroad which has recently been cut through my garden there are plants about as thick as they ought to stand; and I have never yet seen one thrown out by the frost; while alsike, red clover, and other plants, are frequently heaved up clear on top.—A. I. R.]

Our Symposium on Wintering.

The Subject Reviewed by a Few of the Prominent Bee-keepers who Have been Successful in Wintering for Many Years back.

ESSENTIAL CONDITIONS; THE MODERN OUT-DOOR AND INDOOR PLANS FULLY DESCRIBED; PACKING; UPWARD AND BOTTOM VENTILATION; SEALED COVERS; SUB-EARTH VENTILATORS; MODEL BEE-CELLARS, AND HOW TO CONSTRUCT THEM.

[A few years ago the subject of wintering was an old and hackneyed one until it was chopped off. There were a good many conflicting theories, and many were losing heavily. But in later years these theories have come more and more into harmony, and success is crowning the efforts of nearly all. It seemed to me it might be well for us to devote one whole number to a review of the subject, to consider the essential features, and those points upon which there seems to be now general harmony of opinion. I therefore asked a number, as before stated—those who write only occasionally, but who nevertheless are very successful—to give us briefly their methods, wherein they attain success, and then to tell us briefly what things they had learned in the last few years.* Among other things, I told them not to be afraid to go over old ground; that we desired to see how many prominent bee-keepers were following essentially the same methods. If these methods should be largely the same, it would be proof that they were nearly correct. While one might suppose that one article might be largely a duplicate of another, each writer treats the subject in quite a different way, as the headings will show.—ED.]

OUTDOOR WINTERING IN VERMONT.

THE IMPORTANCE OF A BROOD-NEST SUITED TO THE SIZE OF THE COLONY.

By J. E. Crane.

About the middle of September, or as soon after as I can get to it, I look over my bees and carefully weigh with my eyes the amount of honey that each hive contains, and set down the amount of sugar syrup that each needs to carry it until warm weather or spring flowers, beside the number of each hive. At this time I also see that each colony has a laying queen. If any are queenless they are broken up. If I find any drone-laying queens, the colony is united with others. I also note carefully the size of each colony, and *reduce the brood-chamber to correspond with the size of the colony.* I then feed sugar syrup, containing some honey, as quickly as possible, in quantity such that each shall have of honey and syrup from 12 to 30 lbs. This is to include the stores of honey in the hive before feeding. I expect to have my feeding all done by Oct. 15th.

I winter my bees on their summer stands, and the next thing to be done is to pack for winter; and I prefer to pack at once as soon as feeding is finished. I was 11 days this year

feeding about 8500 lbs. of syrup, most of my bees being from 3 to 11 miles from home, with only one horse to draw it.

For packing I use sawdust, chaff, leaves, and planer-shavings. All are good, but the wind blows the leaves at times very uncomfortably, and chaff is very apt to attract mice; and the sawdust has a way of getting through any little crevice or hole, so I dislike it, and prefer planer-shavings to any thing else.

As I leave the packing around the sides of the brood-chamber during the summer I have little to do but spread a cloth over the top of frames, and fill one side of the brood-chamber, if empty, with shavings, perhaps a few around the upper edge of the brood-chamber, and lay over the whole a cushion filled with packing, and tuck down snug and warm.

For cloths to lay over the frames I use cotton cloth, old pieces of carpeting, old woolen cloths, straw matting, and any thing that will let the moisture pass through. Burlap is good. Matting made of cocoanut fiber is perhaps the best, or at least will last longest. I have used enamelled cloth, and very strong colonies seem to winter well under it; but I do not find the combs as dry and clean as when some cloth of open texture is used.

About half or two-thirds of the way from the bottom to the top of the brood-chamber in front I have a tube $\frac{3}{4}$ or $\frac{1}{2}$ inch in diameter to connect the inside of the chamber with the outer world. In other words, I have an upper entrance so that, should the lower entrance get clogged with dead bees, the upper one can be used by the bees and so prevent their worrying themselves to death.

Treated in this way, bees winter here in Western Vermont year after year safely, and, I believe, economically. My bees, so far as I know, are now all snug, and warmly packed this Oct. 24th, and will require very little farther attention until April. Should the weather be warm, the bees can fly and enjoy it. If cold, they can remain snug and warm in their nests.

Were I asked what I have learned in recent years in wintering that is of importance I should say, *the value of having the size of every brood-chamber correspond with the size of the colony that is to occupy it.* Quinby, in "Bee-keeping Explained," says that a small colony will consume nearly as much honey as a good-sized one; and when both are wintered in the same size of hive he is undoubtedly correct; but my experience has been that, when the brood-chamber is reduced to fit the colony, the consumption of honey during winter does not seem proportionately greater for the small colony than the large one. Nor yet do I find the loss greater of small colonies properly put up for winter than large ones.

My theory is, that, if a good-sized colony should have eight frames to winter on, and 30

*I did not call on the regular contributors, because we were familiar with their methods.—ED.

lbs. of honey, a colony half its size will winter well on four combs and 15 lbs. of honey. Of course, after warm weather, and brood is maturing rapidly, the small colony will need more honey than the large one in proportion to its size, for it will mature brood almost as fast, oftentimes.

Now, if it is such an advantage for a small colony to have its hive reduced, would it not be a saving in honey to place a strong colony on, say, six combs? I answer no. They would be likely to consume even more honey than if left properly packed upon eight combs. The strong colony is liable to be overwarm and restless, and to rear a large amount of brood in winter, thus wasting its stores and vitality both. So I use the division-board freely, and have brood-chambers of all sizes from four to nine or ten Langstroth combs, and I have wintered very small colonies upon three combs with entire success.

Last winter, in my home yard and one three miles west, consisting of over 200 colonies, I lost, previous to May 15, but four, and one of these was broken up by thieves. Another was overlooked, and the frames but partly covered by a loose board, leaving less than one per cent loss from wintering. In another yard the loss was, I think, less than two per cent.

In another yard of over 125 colonies I thought I would experiment, and left several colonies upon eleven combs, and lost nearly all of them, while the loss among the rest was very trifling—perhaps one or two. In still another yard I experimented upon a larger scale. Most of the colonies in this yard were under size, and I left the most of them upon seven or eight combs, when they should have been placed upon from four to seven, and I lost not far from 25 per cent of them.

I made these experiments because I thought I had been running to the other extreme, and to learn if possible the golden mean.

Middlebury, Vt.

INDOOR AND OUTDOOR WINTERING IN YORK STATE.

ADVANTAGES OF SHALLOW FRAMES FOR INDOOR WINTERING; RAISING THE HIVE UP FROM THE BOTTOM-BOARD BY A SHALLOW RIM.

Friedemann Greiner.

In wintering my bees I practice both methods; viz., wintering on summer stands in permanently packed hives (chaff hives), and cellar wintering in light single-walled hives. I am generally successful with both of these methods. My way is as follows:

When I remove the surplus-cases after the honey season is over I ascertain whether there is a sufficient quantity of honey in each hive. I do not consider it necessary nor advisable to

weigh or lift each frame in each hive, as Mr. Doolittle recommends. I simply spread the brood-nest in the center, to see how far down there is any honey. I can then judge whether a colony has honey enough or not. I almost always find some colonies extremely heavy, a few too light. I make a note of this, and seize the first opportunity to make an exchange between the light and heavy colonies. I also satisfy myself at the time of removing the last surplus-cases as to the presence of a queen. Capped brood at this time I take as a sufficient indication, and I can almost always see whether or not there is brood when I spread apart the central frames, as already explained in the case of ascertaining the amount of honey.

My hives which I use for outdoor wintering are packed with from 2 to 3 inches of chaff, moss, or sawdust. I own up that I am one of the old fogies, using a honey-board. This I remove when preparing for winter; put on a quilt instead, with a 5 to 6 inch cushion over the same; a Hill device I do not use. After my hives are "fixed" up, say by Nov. 1, I scarcely look at them until the following spring. I give full entrance ($\frac{3}{8}$ x 8 inches), and like the idea of setting up a short piece of board, leaning against the hive, protecting and shading the entrance.

The cellar which my bees in single-walled hives are wintered in is under my dwelling-house. This cellar is also used for storing potatoes, vegetables, and provision in general, but is partitioned off and made perfectly dark. The sash of the only window is covered with tarred paper, and hinged to the casing so I may open it or shut it by means of a string without entering the bee-room itself. The window-casing is covered with screen, inside and out, and the space between (10 inches) filled with fine hay. A thermometer is kept in the bee-room, and arranged so I may read off the temperature by opening a slide from the other part of the cellar.

After the middle of November, on a cool, dry day, my bees are taken in and stacked up four high on a foundation of scantling. I leave on the bottom-boards and honey-boards; but I like the idea of placing a two-inch rim, size of hive, between bottom and body, except in case where a very shallow frame in a single story is used.

Ordinary cellars do not maintain an even temperature; at least, my cellar does not; so I keep close watch, especially during changeable weather. By opening or shutting the window I can regulate the temperature pretty well—enough so that I have been able to winter my bees in this cellar for ten years with very little loss. About April 10, or when the bees wintered out of doors begin to bring pollen, I take all colonies from the cellar, and do this during the night. In placing them on their stands I pay

no attention to their former location the fall previous.

Now as to what I have learned during the last few years in regard to the matter of wintering:

Upward ventilation through five or six inches of chaff has proved much better than a sealed cover for outdoor wintering.

A very shallow frame (half-story frame) in a single story has given me best results in the cellar, which I explain as follows: In so shallow a brood-nest the cluster of bees touches top and bottom. Any bees, when about to die, can not accumulate, but leave the hive and die on the cellar-bottom, which should be covered from time to time anew with dry sawdust. Purer air is thus secured to the colonies, and combs remain sweet. I have never as yet found a moldy comb in these shallow hives.

For ten years I have been a good deal like the man trying to teach his cow or his horse to live without eating, but failing, just as he thought the feat about accomplished. That is, I have been trying to winter my bees without sufficient protection, but I nearly always failed. I can look back upon the second decade of my bee-keeping career with greater satisfaction; for my loss has seldom amounted to over five per cent in one year during this time.

After writing my article so far I find I have omitted to say any thing about the character of the winter food. Of course, I should want to winter my bees upon wholesome food. But how can we tell beforehand any thing about it? There is the rub! Honey-dew might be extracted, and syrup fed instead; but who can know beforehand that honey-dew would prove fatal in its effect as a winter food? The only time we ever had much honey-dew in our hives, our bees, left out on summer stands and those taken out in February, or as soon as they became uneasy, wintered par excellence. To anticipate the true character of the stored food, I imagine, is a difficult matter. As Dr. Miller often says, I don't know any thing about it; therefore I leave this factor entirely out of my calculation. If I were situated in a different location I might do differently.

Naples, N. Y., Oct. 15.

WINTER CASES.

DOUBLE BROOD-CHAMBER PREFERRED; IMPORTANCE OF SPACE SECURED BY A RIM UNDER THE BROOD-FRAMES FOR OUTDOOR WINTERING; THE TENEMENT PLAN OF PACKING.

By J. A. Green.

I am asked to let the readers of GLEANINGS know how I winter my bees, and what I have learned during the past three or four years that is of practical benefit along that line.

My method of wintering has been given in these pages before, but it will do no harm to repeat it. As early as possible after the honey-harvest is over (which in this locality often continues good up to the 20th of September), I see that each colony has a sufficient number of bees, and honey enough to last until honey may be gathered again. As to the first point, I do not consider an extra-large colony more likely to winter safely than one that is a little below the average in numbers, but otherwise in good condition. I consider it very important that they should have honey enough so that I may feel perfectly sure that no more will be needed until it can be gathered from the flowers.

After my bees are prepared for winter I do not expect to do any thing more to them, as long as they are apparently in a normal condition, until the approach of the next honey season makes it necessary to prepare them for it. As this means that they are to be left undisturbed for nearly or quite six months, an abundance of food is necessary. A colony will get through the winter on 20 lbs. of honey, often less; but it is liable to need help to get it into good condition for the harvest. So if a colony has less than 30 lbs. I mark it as likely to need attention in the spring.

I use the double-brood-chamber hive, made almost the same as the Heddon hive, and consider that the bees winter in it rather better, on an average, than in the single-story hive.

Each hive is raised from the bottom-board by putting under it a frame or rim that leaves a space of about two inches between the bottom of the frames and the floor of the hive. This I consider very important. That the bees appreciate it is shown by the fact that they almost invariably cluster in this space below the frames. A colony in a solid cluster this way, with plenty of honey within reach, is in an ideal condition for wintering.

The rim which raises the hive is so made that the usual entrance next to the bottom-board is closed, and an entrance left at the top of the rim. This entrance is $\frac{3}{8}$ x 12 inches, giving an abundance of ventilation. The sides extend four or five inches beyond the front of the hive, and are covered there, making a "bridge" which supports the outside packing and forms a vestibule to the entrance, protecting it to a considerable extent from the wind.

Dead bees which fall from the cluster drop entirely free from the frames, and there is no chance of the entrance becoming clogged with dead bees or ice. I make these rims of lath or other thin lumber. The only drawback to their use, aside from the slight expense and trouble, is that they must be removed before the bees get too strong in the spring, or they will fill up the space with comb. This some-

times makes it necessary to unpack the bees sooner than I should otherwise like.

I believe thoroughly that outside packing pays. My favorite method is to pack four colonies together. During the summer the hives are in groups of four, two facing east and two west. They are far enough apart to allow of working all around them easily; but on the approach of winter they are moved close together. A large box (or, rather, a rim) without top or bottom is then placed around them, the ends resting on the "bridges" over the entrance so that the bees may fly undisturbed, the sides resting on the ground. The sides and ends are separate panels, which are lightly tacked together at the corners, just before they are set into place. The four hives are now about two inches from each other, with a space of three or four inches all around the outside, and six or eight inches over the top.

I generally use planer-shavings for packing. Leaves of the softer varieties are good; but I would not use chaff or straw, as the grain they are apt to contain is an attraction for mice. The whole is covered with a good roof—one that will not leak or blow off.

The hives I use are covered with a flat board cover, and this is left just as it was during the summer.

Several years ago I wrote several articles in favor of sealed covers for wintering—a method which was then gaining favor rapidly. For some reason, which I could never understand, the tide turned. Led by the editor of *GLEANINGS*, many of the new converts recanted, turned right-about-face, and declared that they wanted no more sealed covers. As I remained silent, and made no further argument or reply to those who criticised the methods I had advocated, some of my friends thought that I too had concluded that I had been mistaken. Not so. I am as firmly convinced as ever that sealed covers, with proper protection, is the proper method of wintering. Argument seemed useless; but when so many went back to porous covering and absorbents, I tried the experiment over, using quilts on a number of hives in order to be sure I was not mistaken. The result satisfied me that, the nearer I could come to a perfectly tight cover to the hive, the better. In practice it is difficult to always have perfectly sealed covers, as I often have to remove covers so late that the bees have no chance to seal them down again as perfectly as I should like; but I use every effort to have the top of the hive as tight as possible.

Single hives are packed in the same way, using a box that is at least three inches larger each way, and six inches higher than the hive.

For a roof, a sheet of corrugated iron is laid over the top and weighted down.

I am convinced that many who have tried outer cases for packing have not been as suc-

cessful as they might have been, because the cases they used did not have room for enough packing, especially on top.

Last winter, for experiment and comparison I left several colonies unprotected, and protected others thoroughly on top, but left sides of hives unprotected. The former all died. The latter were alive in the spring, but so weak that they soon dwindled away. The mortality among those packed was not over ten per cent.

Ottawa, Ill., Oct. 30.

WINTERING IN WISCONSIN.

THREE IMPORTANT CONDITIONS.

By C. A. Hatch.

Three things are of first importance to winter bees well: 1. Good stores; 2. Good bees; 3. Proper temperature. Given these three essential conditions, bees will winter with many conditions that otherwise are unfavorable. Like a man of good constitution, great vitality, and good health, the amount of abuse he will stand and be none the worse is surprising. Just so with bees. Give them the three things named above, or even the first two, stores and bees of the right kind, and they will live under many adverse circumstances. But take away either of these two, and no amount of coddling and fussing will make their wintering a success.

The sooner we get to recognize what are the essentials, the better it will be for us; for a great amount of effort has been directed to things that are of only secondary importance. Ventilation is of importance, but not first; so is moisture: but both, as affecting temperature, become all-important.

GOOD STORES.

Honey from flowers of any kind, if well ripened and sealed over, is all right, although there seems to be a difference in these, more on the account of the liability of being something which is *not* honey being stored with it than from the honey itself. Any thing that would cause the honey to ferment, as juice from any kind of fruit, sugar-cane, or any thing of the kind, seems to be detrimental. Honey-dew in our State, no matter what others say, is very poor winter food. The very best stores yet found is wild-bergamot honey.

That the winter food should be sealed is not essential, if it be thick; but sealing helps it about absorbing moisture and taking in ferment germs.

CHANGING STORES.

If our bees get improper food into the hive it becomes a serious matter to change this for the proper kind, for experience has taught that there is a right and a wrong way to do even this. Changing the frames of poor for frames of good honey is all right if thoroughly done early enough in the season so that the bees can

arrange themselves for winter; but to wait until almost time to put them away for winter, and then take out a few outside frames and put in the others does but small good, for the bees have arranged a winter supply around the brood-nest, and it is a chance if your good honey is touched at all, for the bees will be dead long before they get to it. Then why not put it in the middle? By this you have divided the bees and changed all their winter arrangements. A neighbor of mine last fall, when our bees all got much honey-dew, took all the honey he could get from 80 colonies, and had to leave 40 with the honey unchanged. In the spring, those undisturbed came out as well as the others, although the best of basswood was substituted for the honey-dew. From this we draw the inference that the only practical way is to remove the honey next to the brood-nest, put in empty frames, and then feed with some kind of a feeder. This gives them a chance to arrange the food in what *they* call the right place. Then arrangement of stores is important. Yes, but not essential. If proper temperature be given, the bees will go to the honey if it is in the hive, whether it is above or at the side or end of the cluster. I have experimented along this line with frames from 5 in. deep up to 19 in.; and, other conditions being right, it made no difference. Sugar stores are all right for winter if fed early, and good sugar is used.

GOOD BEES.

The next essential does not refer to any race or mixture of races, or any strain, but simply means bees of the proper age, not too old nor too young. If they are old enough to have a good fly before cold weather sets in, they are old enough and none too young. On the other hand, if they are hatched too late to get this flight I would call them too young for the best results; and if breeding stops early in September, most of the bees will be too old to come out alive May 1st, which they must do to have their places filled by new recruits. In case nature does not furnish enough bloom to keep breeding going until Oct. 1st, feeding would be essential; and this should be done with the best of honey or granulated sugar; for all not used in breeding goes to supply winter feed, and it would be like compelling your cows to eat moldy hay to put poor food before your bees.

TEMPERATURE.

This in our climate is best controlled in an underground repository which should be well under ground, and controllable at a temperature of 40 to 45 degrees. The cellar should have ventilation, controllable, but no draft; best obtained by a pipe connecting with a chimney or stove above, in which a fire is kept most of the time. Details of arrangements in cellar may be considered, such as

VENTILATION OF HIVES, ETC.

Top or bottom ventilation of hives has been a vexed question with me, and I am not so sure on this point now, but have come to this conclusion: if much bottom ventilation is given, but little at top is needed; and if much at top, but little at the bottom. I am inclined to large opening at the bottom and none at the top, for the reason that it seems to preserve the natural heat of the cluster, and at the same time allow all dead bees to fall away from the combs, and thereby avoid foul air and contamination by mold and decay. I have practiced leaving the bottom-boards off entirely, and setting the hives so as to have a space of about 8 in. wide the whole length of the hive clear, and leave the quilt and cover on; also the honey-board if the hive had one on in the summer.

TIME TO PUT INTO THE CELLAR.

The 20th of November my bees are put into their winter quarters, as a rule, and remain there undisturbed until April 1st to 10th.

Ithaca, Wis., Oct. 10.

INDOOR WINTERING IN YORK STATE.

VENTILATION AN ESSENTIAL; HIVE AND CELLAR VENTILATION; A VARIATION IN TEMPERATURE BENEFICIAL; HIBERNATION.

By P. H. Elwood.

It is now too late to make preparations for winter, and I write this assuming that such preparations have already been made. Strong colonies, with plenty of good honey or its equivalent in sugar syrup, are the bases of all successful wintering. I know weaker colonies sometimes pull through finely; but as a rule they do not. The same with colonies rather short in stores. Not only do they need enough to carry them through the winter, but enough to last through the spring. More honey is consumed through the spring than through the winter. The stores should also be so located that the bees will not be compelled to change their brood-nest during cold weather.

In this locality bees are nearly all wintered in cellars. Bees often winter as well out of doors, and occasionally, in an open winter, even better; but now and then we have a winter so severe with steady cold so long continued that a large proportion of the colonies out of doors perish.

For indoor wintering the conditions of most importance are temperature and ventilation. As it is so difficult to control temperature in repositories above ground, such have been quite generally abandoned. The temperature named by different writers varies from 38° to 50°; but for the average cellar, 42° to 45° is probably about right. In a very dry cellar the temperature of 38° to 42° may do very well; while in a very damp cellar the temperature

might be raised to 45° or 50°, and yet be no warmer.

The ventilation of the hives also makes a difference as to the temperature of the cellar; for with upward ventilation to the hive, a higher temperature may be maintained in the cellar.

The purity of the air also makes a difference, for the bees will remain quiet longer in a high temperature if the air is pure. Whatever the other conditions, all agree that a freezing temperature is too low. Far better to let bees remain on their summer stands unprotected than subject them to this. In the damp atmosphere of a cellar this low degree is apt to cause a dangerous condensation of moisture upon the combs of honey.

Ventilation is necessary, both to control the temperature and to maintain the purity of the air. The heat of the earth is the main dependence for controlling the temperature of cellars; but with a cellar fully stocked with bees, recourse must be had to ventilation. At no time, no matter how cold, can we close all ventilation to our cellar without causing a dangerous rise in temperature. Again, when we have a very warm spell of weather we find it necessary to throw open all ventilators at night, including doors, and partially close them in the morning. Sometimes the temperature does not fall much in the cellar; but we find the bees quieter in the morning in the pure air. Sub-earth ventilation, if well put in, is useful at such times; but with a cellar only partially stocked with bees it can be dispensed with.

Ventilation for maintaining the purity of the atmosphere has been a disputed point; but during the last few years it has been so generally accepted by intelligent bee-keepers that but few remain to dispute it. The necessity for such ventilation was abundantly proven many years ago; but so many had wintered successfully without any provision for change of air that it was thought some mistake had been made by the claimants. It is now generally admitted that the mistake was made by those who did not admit the claim, in overlooking the factor of natural ventilation, which, in many repositories, is abundant for the number of bees kept in them. By natural ventilation is meant the change of air taking place through the crevices and materials, such as wood, mortar, brick, and stone, of which the building may be constructed. For fuller account of natural and artificial ventilation, see *American Bee Journal*, p. 233, 1878.

During the last few years we have not gained so many new points, but have more fully established the old ones. That bees enter a state of quietude that may rightly be called hibernation is fully accepted by us. Like hibernation in many other animals, this sleep is not continuous, but at intervals the bees awake to partake of food. Prof. McLain states this interval to

be about a week with the honey-bee; but we need further observations to confirm or establish this period. We also need to look up the conditions most favorable for this awakening. My own observations lead me to believe that, when the temperature remains uniformly low for a long time, the awaking process is either delayed too long or is not complete enough, so that many bees either suffer from hunger or perish from starvation with plenty around them. That is, a variation in temperature within certain limits is better than absolute uniformity. Mr. Quinby was of the opinion that a fire in a bee-cellar every few days would be beneficial. We put our bees in the cellar with plenty of lower ventilation (about 20 inches), but the upper part of the hives is as close as carpentry and metal corners can make them. A moderate amount of upward ventilation may be better in damp cellars, or in cellars where it is difficult to keep the temperature down. Our cellar is overstocked, and we have to remove a part of our bees too early (in March). Upward ventilation might benefit us, but our hives are so constructed that we can not conveniently make the change, so we shall, instead, somewhat reduce the number of colonies put in the cellar. Spring dwindling is a part of poor wintering—the last stage. The vitality of the bee is exhausted, and it falls a prey to every wind that blows.

For fuller account of hibernation, see article on "Hibernation," republished in GLEANINGS a couple of years ago.

Starkville, N. Y., Oct. 24.

THE UP-GROUND REPOSITORY PLAN.

LOW TEMPERATURE TO START ON AND HIGHER TEMPERATURE FOR BREEDING; ARTIFICIAL HEAT AND ITS ADVANTAGE.

By H. R. Boardman.

A review of the best methods of wintering at this time, when bee-keepers are beginning to think of the long helpless sleep of their bees during the cold months of winter which are near at hand, will, no doubt, prove profitable to many who are hesitating as to what they ought to do. I will briefly review my own methods, which have been given before, and which have proved entirely successful and satisfactory.

I winter in a bee-house planned and prepared for the purpose. I have no confidence in outdoor wintering by any method that I know. I have for quite a good many years experimented in that direction by leaving some of my colonies out on the summer stands. The results are quite encouraging some seasons; then comes a cold winter, and the bees die, or winter poorly. These experiments have proven expensive to me, and I shall hereafter be satisfied to winter all of my bees inside.

Whatever preparation is to be made by way of feeding or handling should be made before the approach of cold weather. This is not as important with indoor wintering, where the bees are to be in a mild temperature, as in outdoor wintering.

The queen is the most important factor in the future success of the colony. Young queens will lay, and keep up brood-rearing later, and begin earlier in the spring, than old ones, thus furnishing young bees for winter, and also building up earlier in the spring, with less liability of queenless colonies; but colonies with such queens will consume more stores. Late queens have these characteristics to recommend them.

I set my bees into the bee-house as near the 15th of November as circumstances will permit. At about this time I watch for a cool day when the temperature is below 32°, and falling, as the bees then handle much better than when the temperature is rising. This may seem a small matter; but it is quite important, and is well worth attending to.

I have a system of locating that enables me to put each colony back upon the stand from which it was taken, when they are set out again, with very little trouble.

It is a system entirely my own, and one I have used in all my work with bees almost ever since I began my experience in bee-keeping. It does away with tags or numbers or marks on the hive except when the hive is removed from the stand. My hives are arranged in rows. The rows are lettered in alphabetical order. The stands, and not the hives, are numbered in the rows. When I am all ready to set the bees into the bee-house, with a piece of white chalk I mark each hive to correspond with the stand upon which it rests; thus:

A 1	A 2	A 3	A 4	A 5
B 1	B 2	B 3	B 4	B 5
C 1	C 2	C 3	C 4	C 5

and so on through the yard. I think the advantages of my system of locating will be comprehended without further comment.

My system of securing abundant lower ventilation has been described and illustrated so many times that I will only call attention to it briefly. It is very simple. I first place a row of covers 5 or 6 inches apart; then pick the hives up in the yard, from the bottom-board, and bring or wheel into the bee-house, on a hive-cart, and set them over the open space on the covers. This will bring the hives about the same distance apart that the covers are. Set another tier of hives on top of these in the same way, leaving the open space below directly under the hive, and so on as high as desired. After putting my bees in in

this manner, if at any time during the winter I should want to refer to any particular colony, or should want to set one or more out on the summer stands, which often happens with me, I should know just where they belonged.

After the bees are all in the bee-house I leave the doors and windows open, giving abundant ventilation and the full light of day until the weather becomes quite cold. By this means the temperature is kept well down, say below 40°. I prefer that the temperature should not be much above this until there are pretty evident signs of brood-rearing toward spring, which will be shown by increased activity of the bees.

After brood-rearing has commenced it is very important that the temperature be kept pretty well up, say 50° to 55°. A low temperature at this time, if long continued, is almost certain to produce unfavorable results. It is at this time that artificial heat plays an important part in regulating the temperature of the bee-house, which is a factor in wintering bees that I could not think of dispensing with; in fact, it grows in favor with me each year, and I would not think of constructing a bee-house without arrangements for this purpose. I never use artificial heat directly in the bee-room, but in a room adjoining. This makes the warming so gradual in the bee-rooms that the changes of temperature are almost imperceptible to the bees, and causes no disturbance.

I want the bee-repository as free from moisture as possible during the entire winter—so perfect in this respect that the stores in the hives will be kept perfectly, without mold or fermentation. This I consider important. Stores demoralized by a moist condition will surely result in an unfavorable condition of the colony in spring, which will continue to affect the bees long after they are set out.

While upon this subject I wish to call attention to the fact that bee-keepers who last winter advocated moisture as a favorable condition in the bee-house have been slow to come forward with a report of their bees after being set out, to substantiate their arguments.

After the bees have been perfectly wintered it is of great importance that they be set out on their summer stands on a warm day when they can at once take a thorough flight. Very serious damage will result from setting out when the weather is cool enough to chill the bees that fly out for the first time.

In regard to winter stores, I consider sugar much safer for that purpose than honey.

UNITING.

There is no time when colonies may be united with so little trouble as when set out of the bee-house in spring. It is unnecessary to give any attention to the queens. I unite at this time by placing one hive on top of another,

using the best combs on top, as the colony will eventually occupy the upper story. I have had both queens continue laying in such united colonies until swarming-time.

East Townsend, O., Oct. 22.

A MODEL BEE-CELLAR.

SMALL HIVES PREFERRED FOR THE CLUSTER.

By B. Taylor.

To winter bees successfully two things are positively indispensable, especially in the northern sections of our country. I regard the condition of the bees themselves as being of first importance. Next, good winter quarters. The wintering-cellar at the Forestville apiary was made by digging into a clay hill with a 30° slope, in bank-barn fashion. The walls are of solid stone 22 inches thick for 3 feet in height. The next 4 feet the wall is only 14 inches thick, leaving a jog on the inside of 8 inches. A sill 2x6 was laid on this jog, and a frame of 2x4 scantling set up even with the inside of the bottom wall, the plate being on a level with the top of the stone wall. This 4-foot-high frame was sealed on the inside with matched flooring. This leaves a space of 8 inches between the inner wooden and outer stone wall. This space was packed with dry clean pine leaves. This prevents frost from entering the cellar through the top of the wall. The floor over the cellar consists of three separate floors of matched flooring with a space of two inches between them. These two-inch spaces are filled with dry sawdust. The first and second floors were covered with tarred sheeting-paper before the sawdust was packed in. This keeps frost out from above. A common frame, four feet high, was made on top of the wall, and a first-class roof of shingles covers all. The cellar is divided into two rooms lengthwise by a board partition so one half the bees could be kept in quiet darkness while the other half was put in or out. An ante-room of 4 feet in front, with one heavy outside and an inside door through the partition into each room keeps out frost from this direction. In the center of the partition that makes the ante-room there is a brick vault from bottom to top of cellar, 4 feet square, with a door in one side. In this vault is a proper stove where a slow fire can be kept to warm up and purify the air when needed. The stove is operated from the ante-room, and does not disturb the bees. The cellar is floored with two inches of cement. There are proper means of ventilation, and the air is pure enough for a living-room. The earth is banked at sides and back end to top of wall; the entrance is level with the bee-yard outside. When the bees themselves are in right condition they winter in this cellar with great certainty. The outside foundation wall to our dwelling is

made by digging a trench 2½ feet deep, and building a wall in it to two feet above the ground. Inside of this wall, and four feet from it, is the cellar wall proper. Dirt is filled in between these two walls to the bottom of the sills. The chimney of the house starts in the center of the cellar, with a flue for ventilating. There is a cement floor three inches thick, with a complete system of underdrainage. There is a brick drain laid in a circle around the house outside, and as low as the bottom of the cellar. The drains have a proper outlet. This extra drainage was necessary because there was a stratum of clay that held water, and the cellar filled five feet deep in rainy seasons. Now it is so dry that the hoops loosen on barrels in winter, and is so warm we use an outside entrance at all seasons. I have frequently wintered from ten to sixty colonies here, and with greater success than in any other repository I ever used.

I have given these detailed descriptions to guide others; for good quarters are vital in *successful* bee-keeping. The best success I have had in preparing colonies for winter was by covering the hives with either cotton quilts similar to bed-quilts, or covers of thick soft felt paper, such as is used under carpets. The covers were held tight to the top of the hive by a frame of inch-square wood screwed down tight. There was a Hill device, or something the same, under the covers. The bees came to the top and wintered directly under and in contact with covers. Where paper was used, a square of light cotton sheeting was put under the paper to keep the bees from gnawing through. The hives were left on the bottom-boards, with an entrance ⅜ high the entire width of the hive, front and rear. They were piled up four or five high, as need demanded. They were put into the cellar about November 1st, and left undisturbed until about April 1st, when they were put on summer stands.

One of the things I have found out in recent years is, that we must have plenty of young bees to begin winter confinement with. From Dec. 1st to April 1st is five months. Bees, as a rule, entirely stop breeding here by Oct. 1st, and do not raise much brood before May 1st. This is *seven months*. I do not believe workers live much longer than this under the most favorable conditions. Bees hatched in August will be nine months old to reach May 1st. I have had the most positive proof in the last two years that they can not be made to live so long by any known skill or perfection of food or quarters. Some claim that bees live very long when idle. I do not believe that men or animals that follow nature's demands as to work shorten their lives thereby. I have observed that loafers do not live longer than the industrious who lead a just and temperate life. I expect to live an active life while I can walk,

and I do not expect to lessen the number of my days thereby.

I have found that bees keep drier, and winter better, when they cluster at the *top of the brood-nest and over their stores*. I have long believed they winter best in a small hive *crowded full of bees*, rather than in a large one in which there is much room *outside the cluster*. Such cold vacant space condenses moisture, and causes mold and bad air. I believe any live thing that was made to live in the pure open air, like bees, are injured by *damp, cold, bad air*.

I have become convinced that bees winter better with just enough always accessible honey in their hives to feed them safely until warm weather. I can keep combs of surplus stores *purer and better in a warm dry store-room* than in the vacant space in a large hive occupied by a colony of live bees.

Mr. Editor, I have, in the above thoughts on wintering, dealt more on general principles than minor details, because I believe minor matters are better understood than general principles. I have noticed that bees winter best in years of good honey crops, and when the hives are heavy with natural stores. I always had the worst luck when the colonies had to be doctored in any way. I have found all kinds of honey, and even honey-dew, when collected in a natural way by the bees, good winter food. One fall the hives were all heavy with honey-dew, and they came out in first-rate shape. I now get nearly all the white honey in sections or extracting-supers, and believe it pays better to use the dark honey for wintering and raising brood than to fuss with feeding sugar.

Who can tell why some colonies live and others die, all having the same kind of stores and quarters, and the same care?

Forestville, Minn., Oct. 16.

ANOTHER MODEL BEE-CELLAR, AND HOW CONSTRUCTED.

SUB-EARTH VENTILATORS, AND WHY THEY MAKE CELLARS DAMP; TEMPERATURE.

By S. T. Pettit.

I make it a point to have my bees in good shape, and well supplied with good stores. When I must feed I bring $8\frac{1}{2}$ wine qts. of water to a boil, then stir in 40 lbs. of sugar; and when that boils I lift it off the fire and pour in 8 lbs. of honey, and stir well. The $\frac{1}{2}$ qt. is for evaporation. I am of opinion that a good deal of loss occurs from too much water in the food. Many colonies fail to do more than just store it. My cellar is constructed in heavy clay, and a shop is built over it. The shop is very warm, and has a 5-inch floor. The cellar is so deep that the shop floor is about even with the surface of the ground. Now, as the earth is always

giving off heat, this depth is of much benefit to the bees. With a cellar so constructed, more air can be admitted, and the temperature keep right, than in one whose walls are considerably above ground, even though they be several feet thick. A brick or stone wall, however well made, can not supply heat; but the earth does, and it will pay to utilize it.

My cellar-walls, though under ground, are as nearly air-tight as can be made of stone and mortar. The wind blows pretty freely through the ground, hence the necessity.

The windows are on the break-joint principle, to admit air and exclude light. They are adjustable to suit the weather. Large curtains of open cloth are hung between the windows and the hives to distribute the in-flowing air.

About the 20th of November the bees are placed in, about 18 inches from the ground. The back end of each hive stands 3 inches higher than the front. I pry up the back ends and slip in $\frac{3}{8}$ inch bits of lath. I leave the cloth, covered with propolis, flat on top of the frames. I like it sealed down air-tight. A chaff cushion is placed on top of each hive. To keep the hives at the proper pitch, a piece of lath is laid across the lower end of each hive on top of the cushion, before placing the next hive on. The walks, to prevent crushing bees, are made of boards, across which are nailed strips $\frac{3}{8} \times 1$ inch. These strips are nailed one inch apart, with edges up. The floor is natural earth, worked down hard and smooth.

A stove is in the shop above, in which I keep a gentle fire most of the winter. With the stovepipe is connected a 6-in. pipe, which extends to within 8 in. of the cellar-floor. A damper is in this pipe. Now, in sharp weather the upward rush is pretty brisk; but with the combined heat of the bees and earth the temperature keeps at about 40 in steady cold weather.

I wish to point out that, although the air may be saturated with moisture at 40°, when it enters the hives and is warmed to the temperature of the bees it becomes thirsty, and takes up the moisture thrown off by the bees, and thus they are kept dry and healthy. This is one reason why the temperature in a damp cellar should be kept down to about 40°; and, more than that, this difference of temperature of the cellar air and the hive air, if the bees are fixed up right, produces automatic ventilation through the hives, and the bees are not obliged to fan to drive out foul air; and that being the case, and their conditions and surroundings being just right for their happiness and supreme comfort, they will become so quiet that not a flutter nor hum can be heard from most of the hives.

I have learned during the past few years, 1. That bees that hum all winter run down in spring more or less, while those that are win-

tered right boom right along, and generally gather a surplus of spring honey, and are ready for any flow that may come. I do some visiting among bee-keepers. 2. That sub-earth ventilators as usually constructed make the cellar very wet, and that they are of but little if any use made of tile. 3. That damp cellars may be made dry by admitting no air that comes in, in any way, through the ground, either through the walls or under them, and admitting air only from above ground. 4. That it is a mistake to leave the bees in the cellar late in spring if they are at all uneasy. If a fine day comes the first week in April, out go my bees. 5. That a good warm cushion on top is all the packing necessary in spring. 6. That bees do just as well with entrances to the north as any other direction, provided there are good wind-breaks to the west and north. 7. That hive air will be purer and dryer, and the bees warmer and more comfortable, with liberal entrances than with too small entrances. Also, there will be less robbing and less fighting among querulous Italians of the same hive; entrances from 3 to 6 inches in early spring, and $\frac{3}{4}$ high. Querulous Italians must have more to keep them at peace among themselves. 8. That bees winter better and do better in spring in small hives than large ones. 9. That bees winter better on 9-in. than on 12-in. frames. 10. That cards more than ten inches deep should have a hole or two made a little above the center of all the combs.

Belmont, Ont., Can., Oct. 19.

[It is very encouraging to note, as one reads over this series of very interesting articles, that the "wintering problem" is not such a serious one as it formerly was; indeed, it may almost be said to be solved if we may judge from the unbroken records of success of not alone the few who have given us their views, but of the hundreds of bee-keepers all over our north lands where winter's rigors hold full sway.

Not all of the writers above follow exactly the same methods; but it is significant that they agree on all important essentials.

These, primarily, seem to be—good bees of right age; good food, and suitable protection. As to food, granulated-sugar syrup fed early enough to be well ripened seems to hold the first place; after that, good light honey. For protection all are agreed that outdoor colonies should be packed in double-walled hives, and that those indoors should be in a frost-proof room, generally under ground, darkened, and capable of good ventilation. It seems to be easier to control temperature in the cellars than in the upground structures.

As to ventilators for repositories: The sub-earth do not receive much indorsement. Mr. Pettit holds that the fresh air admitted through underground tubes acquires an undue amount of dampness, and is, therefore, detrimental. The ventilation that is preferred seems to be from doors and windows that may be opened at intervals at night.

It is significant, too, that the ventilation of the hive should be from the bottom, either by leaving the bottom-board off entirely and piling the hives over the spaces of those below, or of raising the hive up on a rim to give air-spaces

under the frames. So far, then, indoor colonies should have tight covers.

When it comes to the outdoor bees, there is a divided opinion as to the desirability of a sealed cover.

All put their colonies into the cellar about the middle of this month, or about the time this journal reaches its readers.

As to outdoor packing, planer-shavings seem to receive a prominent recognition; and perhaps I might say in this connection that we now prefer them to chaff. They keep dryer, and are more easily obtained.

Hibernation! what a bone of contention that used to be among the bee-brethren! After it had been harped upon and harped upon again, until it was hoped the word would never see the light again on the pages of a bee-journal, it was dropped, but not without some of the brethren feeling that they had been deprived of a right to the "last say." But as Mr. Elwood has introduced it in this number he has shorn it of all its old "non-swallowable" features (excuse the coinage), and left it where there is no chance for argument. Either we have advanced in our knowledge and practice of wintering, or else he has explained it so that we understand the term better when applied to bees. At all events, we can agree with him, I think.

There, now, it just occurs to me that I had asked Dr. Miller to review these articles in our next issue—to digest them, as it were, and give us the solid meat. So I did; but, oh my! I haven't begun to review them or sum up the good things. Even if I have, I may have seen through a glass darkly. Well, doctor, we will suspend judgment until we see through your eyes, after which the subject will be open for further discussion if thought necessary.—ED.]

FEEDING BACK; AN INTERESTING SERIES OF EXPERIMENTS.

Question.—I saw a little while ago, in one of my papers, something about "feeding back." Can you tell us in GLEANINGS what is meant by this, and is there any profit in it to the person who practices it?

Answer.—Undoubtedly, every one of the older readers of GLEANINGS knows what is meant by "feeding back;" but in order that the younger readers and our questioner may know just what this term means I will say that feeding back is the feeding of extracted honey, taken during the honey harvest, back to the same colony from which it was taken, or any others if so preferred, after the harvest is past, for the purpose of having said honey stored in sections, the colony at this time having been fixed for section honey. The object of such a procedure is to get an article of less price converted into one which brings a greater price. By using the extractor during the honey-flow, from one-third to one-half more honey is obtained than would have been secured had the colony been worked for section honey; but said honey does

not bring more than about half the price comb honey in the sections does. From the above it will be seen that, if a way could be devised whereby the greater quantity of extracted honey could be gotten into the same amount of comb honey, a great gain could be made to the apiarist. This idea has caused much excitement in the past, and quite a few of to-day are still trying it. I know of no better way to illustrate what I wish to say than to give some of my experiments conducted during the past.

Some eighteen or twenty years ago the first comb foundation of any amount was sent out; and as the bees accepted it readily I thought here was a chance to make a profitable business by extracting my honey during the flow of white honey, and feeding the same back to the bees later on. By the use of foundation, much could be saved the bees by way of comb-building. Accordingly, after the harvest of white honey was over, I prepared three colonies that were strong in numbers in this wise: After contracting the brood-nest so that only combs full of brood remained, the first was given 28 two-pound sections (as that was the size I then used), filled with foundation, together with four sections filled with comb, as bait sections. The second was given 21 sections, from one-half to two-thirds full, for the bees to finish up, the 21 weighing, when put on the hive, 35 pounds. The third was given 21 sections with only starters in them, the same being a triangular piece of comb, whose length was two inches on each side. Each colony was fed all they would carry, and a record kept of each. The first feed, each took 15 lbs.; and, soon after, those having the sections two-thirds full began lengthening the cells and storing this fed honey; and when they were completed ready for market, I had fed 42 pounds of extracted honey. Upon weighing the sections again, I found they weighed 47½ lbs.; so I had fed 42 lbs. to make a gain of 12½ lbs. in the sections.

Thinking that, perhaps, they would do better on a second lot, I immediately put on 21 more, weighing 34 lbs., and fed 39 lbs. to get them finished. These were not filled so full, and weighed only 46 lbs. when finished. So I fed 39 lbs. this time to make a gain of 12 lbs. in the sections, the second trial. No. 1, with the foundation, were fed till I had given them 134 lbs., when I took the sections off, having 22 finished, which weighed 49½ lbs., and 8 unfinished, weighing 13 lbs., so I had 62½ lbs. gross weight in return for 134 lbs. fed.

I find by my diary, from which the above is taken, that the experiments with No. 3 were never completed. After I had fed them 50 lbs., or thereabouts, they went to building comb quite nicely; but it soon seemed to become an old story, and after a while they simply lived out of the feed-dish, and did nothing else.

Later on the papers gave out that, to succeed

in this feeding-back process, the honey must be thinned to about the consistency of the nectar coming from the fields, so I tried this, and have tried, many times since, experiments similar to the above, varying them as new ideas were suggested in the papers, or came to me from my own brain, but always with about the same results as given above. In all these feeding operations I have ascertained this fact, that bees fed in excess of what they consume in feeding the brood become idle, as far as field work is concerned, simply living out of the feeder, not bringing in an ounce from the fields, while those not fed will generally get a living, and in some instances make a small gain in their stores. If fed when honey is plentiful in the fields, they will store no faster out of the feeder than others not fed will from the fields; while those storing from the fields work in the sections with double the energy which those do which are being fed.

The experiments given above prove either that I have not "caught on to the matter" or that the doctrine of "feeding back" is a fallacy; and, so far as my experiments go, answers the questioner in the negative.

Another thing is proven by these experiments, which is, that the stories going the rounds of the papers every little while about comb honey being made by feeding glucose or other sweets are merely newspaper canards; for no one, at present prices, can make it profitable to raise comb honey other than by the good old way of having the bees bring in the honey from the fields; and no one is foolish enough to go to the trouble and expense of feeding sweets to produce comb honey unless there is some dollar-and-cent profit in it. People who start such stories, to the injury of a legitimate business, would do well to know something of the nature and habits of the bees, before putting sensational stories before the too credulous public as facts.

[These experiments, especially from the hand of Doolittle, are interesting and valuable. If our friend D. has ever given them before in print in just this way I was not aware of it. It is worthy of note in this connection, that a good many other careful experimenters have come to about the same conclusion; viz., that feeding back doesn't pay. I know there are some who think it can be made profitable, but I have often wondered if they took account of all the costs.

If feeding back thinned honey is not a paying operation, would the feeding of *sugar* syrup be any more so? If that is true, then sugar-syrup comb honey would not be produced to any great extent before it would put the producer of it in a bad plight financially. In other words, the product would die its own natural death. If there is any sugar honey on the market anywhere in this country, I am not aware of its existence. If it is to be assumed that it would be sold under its real name, then it certainly is not advertised or quoted; and why? Perhaps because it can not compete with natural honey from flowers.—Ed.]

SWEET CLOVER: WHERE IT GROWS; NOT A NOXIOUS WEED.

Dr. Miller:—Will you please give in GLEANINGS the season of sweet-clover bloom? I think of putting in a field if bloom suits, as my Belgian hares could use the hay to a T. Would I have a stand if I sowed the seed in March on top of bare ground, like buckwheat stubble? I understand it grows easily. W. W. K.

Pottstown, Pa., Oct. 14.

Dr. Miller replies:

I don't know just when sweet clover commences to bloom, but it's some time after the beginning of white clover—perhaps a month later. This year it was at its best about the middle of July, but that was unusually early. It continued to bloom till the weather was too cold for bees to fly. The first frosts that kill all the tenderer plants seem to have no effect on sweet clover, and the bees can be seen working on it after the weather becomes freezing cold, providing a warm day comes.

I've no doubt it would come all right if sown in March. It grows very easily where you don't want it to grow, and will do well in very hard ground; but I've known it to fail of a catch in very carefully prepared ground. It doesn't seem to do as well usually on soft ground, but perhaps that's because it is sown too shallow. I've seen some fine growths on soft ground where the seed was plowed in. A little patch of that kind on my own ground would make good mowing in the latter half of October. I've just been out and found one stalk that measured 29 inches. But then I've found another patch nearly as good on very hard ground. If sowed shallow on soft ground it may heave in winter. Stamped in on the roadside it will stand the severest winter. If you sow on buckwheat stubble in March, merely letting the seed lie on the surface without covering at all, I don't believe much of it will come. Scratch it in or else plow it in.

C. C. MILLER.

[Sweet clover, it is true, will grow where you don't want it to; but at the same time it is not a noxious weed in the ordinary sense of the term. Again, it won't grow where you want it, especially on the better soils. It seeks dry waste places in the hard clay along the roadsides and railroads—places where nothing else would or could possibly grow. If, however, instead of seeking such places it sought out the best of our farms, and if, too, it were hard to eradicate, we might call it a noxious weed.]

With us it begins blooming just about as basswood ceases, and continues until a couple of weeks before frost. Along the latter part of July and first part of August it often yields just enough honey to be perceptible in the hives, and enough to keep robbers kind o' half

way decent during our queen-rearing operations.

The plant is destined to take a much more prominent place among our honey-plants—the more so as it is occupying otherwise waste lands, and comes after the regular honey-flows. Farmers are slowly beginning to learn that stock will eat it, and this will serve to break down their old prejudice against it.—ED.]

OLD FOUNDATION IN OR OUT OF THE BOX READILY ACCEPTED BY THE BEES.

Ed. Gleanings:—In Oct. 15th issue you ask for experience from readers in the line of using foundation the second year with exposure to air, as suggested by the zigzagging of the bees of Bro. Israel, which he calls cross-eyed bees. They must have been emulating the course of the children of Israel in entering the promised land.

I remember of using, several years ago, quite a quantity of thin section foundation the second year. Part of it had been kept in the bulk as I received it, and part had remained in the sections over winter. If I forget not, I had some of it as narrow starters on brood-frames over winter. Part of it was "tissue" foundation, from W. W. Bliss, of Duarte, Los Angeles Co., and was well named, from its pliability, both the first and second seasons, even at low temperatures, where other foundation would break. Part of it was very brittle and glassy, so that I had to be careful in using it.

My bees at that time were Cyprians, pure, and hybrids; and, while cross-hearted in the extreme, they evidently must have been straight-eyed, for they pulled out the foundation all right and built things true in every section, regardless of the condition of the foundation.

CLOSED-END FRAME PREFERRED, AND WHY.

I can not but say a word regarding your frame-spacers—see same number of GLEANINGS. I like the closed end frame for a self-spacing frame. My preference is for Alley's Bay State hive, not patented, or some modification of it, as I am not sure that the hives I have made and used are modeled accurately after it. I believe it to be the best hive in use. The Aspinwall ought to be a very good one. I have found closed-end frames, lifted out and replaced from above, to be remarkably easy to handle. They kill fewer bees; they are handy to put into place; they have been a real delight to me. There is no need of trouble with propolis. If one only gets the knack (or, as F. Thompson says, the "kink" of handling them, they are easily operated, and there is no awkward situation in their use that I have not found to be worse duplicated in the ordinary narrow hanging frame. A. NORTON.

Monterey, Cal., Oct. 28.

[Your experience confirms that of Dr. Miller and others. It looks now as if all old foundation were perfectly good, whether kept in boxes or in sections exposed to the air. Friend Isra-

el's bees must have been cross-eyed for other reasons.

As to the closed-end frames, there are many things in their favor; and as between them and Hoffman frames I don't think I should have much choice. We adopted the Hoffman because they were better adapted to the hives generally in use. The Hetherington Quinby is one of the best closed-end-frame hives in use—perhaps the best. I know it is used extensively, and is easily handled.—Ed.]

OLD FOUNDATION IN SECTIONS ALL RIGHT.

In a footnote to an article by J. P. Israel, on pages 771 and 772, you ask for experience in regard to old foundation. I have taken about 400 pounds of nice amber comb honey from 20 stands of bees (of mixed breed) this fall, and it was all stored on foundation that had been in the sections and stored supers for three years, and there was not a poor comb in the lot except two or three, which were fastened to the divider. I use Heddon supers.

Lacota, Mich.

E. A. MALLORY.

[These are just the kind of reports we want. Let's have lots of them, giving actual facts. It is proper to remark right here that friend Mallory's experience agrees substantially with what Dr. Miller recently said in a Straw.—Ed.]

CROSS BEES; HOW BURNING OLD HIVES AND BROOD-FRAMES STIRS THEM UP.

In reading your A B C book I have not noticed any precautions against burning wood with bee-gum or wax on. A few days ago I noticed that our bees were unusually cross, and I couldn't account for it. They would fly at anybody anywhere near. I couldn't even stay around to watch them. Upon inquiry I found that my brother had started the fire that morning with kindling-wood that had more or less wax and bee-gum on it. Father says that, in the East, when he used to hunt bee-trees, by rubbing wax between two hot stones he could draw bees from all around the country. Among some friends who came to see us were some children, who, after being here a few days, thought they would like to have a bonfire. I told them all right, only to be careful not to put any thing on that had wax or bee-gum on it into the fire. Presently I noticed that the bees were after them in good earnest, and I had to go to the house myself to keep from getting stung. One of the children got quite badly disfigured after they had been chased into the barn several times. On asking them what they started their fire with I found that they had used the shavings off from old brood-frames, which I had lately cleaned. Burning any thing of this kind seems to bring robber-bees around more effectually than any thing else I know of. The scent of burning beeswax does not seem to limit itself to any locality. If we have any thing of this kind to burn we wait till night comes on. Doubtless, burning old hives to destroy foul brood, or using them for kindling-wood, as recommended in the A B C, can be done with

perfect safety if the apiary is not near the spot. Fountain, Col.

J. W. CROUCH.

[Yes, it is true that the burning of parts of hives smeared with propolis and wax will make bees cross, especially if they have been in the habit of robbing. Nothing, I believe, is said concerning this except under "Bee-Hunting," where it is directed to make a smudge, to call the bees in the woods, by burning old comb. I will call more particular attention to this under "Robbing," in the next edition.—Ed.]

AN APPEAL TO THE BEE-KEEPERS OF WISCONSIN.

Some of you have seen the report of N. E. France, in GLEANINGS for June 1, regarding the efforts that were made by the Southwestern Wisconsin and the Wisconsin State Bee-keepers' Associations to get the passage of a foul-brood law, providing a foul-brood inspector for Wisconsin. Mr. France expended \$25 in railroad fare and expenses while working to get the bill passed. The bill as you know was lost; but we as bee-keepers feel that we must not give up until we have accomplished our purpose of getting a law for our State similar to the Canadian law. We must have money with which to pay the expenses of Mr. France, and for a fund to provide for future expenses in pushing this matter through the legislature. We therefore appeal to every bee-keeper and supply-dealer in our State, or interested therein, to send contributions for this purpose to N. E. France, treasurer of the Wisconsin State Bee-keepers' Association, Platteville, Wis., on or before Jan. 1, 1896; and if there are any who are absolutely unable to give us financial support we ask you to write a letter to Mr. France, showing your interest and desire to have this law passed, which is of such importance to protect our chosen pursuit.

F. WILCOX,

Pres. Wis. State Bee-keepers' Ass'n.

H. LATHROP,

Sec. Wis. State Bee-keepers' Ass'n.

N. E. FRANCE,

Pres. S. W. Wis. Bee-keepers' Ass'n.

M. M. RICE,

Sec. S. W. Wis. Bee-keepers' Ass'n.

A GOOD REPORT AND A KIND WORD.

Mr. Root:—Our bee season is over; and as it has been a successful one I thought a few lines would not be out of place, so I write you. My bees, spring count, numbered 34; extracted 13,200 lbs. of honey, and increased my apiary to 90. Of course, to some of you old and experienced bee-keepers this may be under the average, in some localities at least. I am only beginning in the business; have handled the frisky little things 15 years, but it does my heart good whenever I hear them humming. I am very much interested in GLEANINGS, also in the hive discussion; also your lean-beef diet. But I think most of your talks on Christ. If he be for us, who can be against us?

San Pasqual, Cal., Nov. 1. J. A. BOYER.

A CORRECTION.

It seems from my article in Nov. 1st GLEANINGS I made an error. It should read, "50 per cent dilute" instead of 5 per cent. This is a warm day. Bees are carrying pollen as in spring.

G. W. MARTIN.

Saltsburgh, Pa., Nov. 5.

OIL OF TAR AS A PREVENTIVE OF BEE-STINGS;
HOW APPLIED.

Oil of tar and some light oil like cotton-seed oil, or sweet oil, mixed half and half, is the best, or, at any rate, the most effective, preparation to keep mosquitoes and other insects from annoying man or beast.

Hawk's Park, Fla.

W. S. HART.

[R. A. Grimshaw, of England, some years ago, put out what was known as apifuge. This was a preparation very similar to the oil of tar you refer to—at least, similar in its effects. I used it some; but as our Italians from imported stocks were so very gentle it was of little use. It was evident, though, that the bees disliked it.—Ed.]

ARTIFICIALLY RIPENED HONEY; A FINE
SAMPLE.

I send by mail a sample of honey which I desire you to test, and also get the opinion of your best experts as to what it is before you give them any information about it.

This honey was taken by me, with an extractor, from old combs in April, 1893, before a cell was capped, and so thin and watery that it was difficult to get the bees from the combs without spilling the honey. It was piped from the extractor into a galvanized-iron tank covered with common muslin, and left standing in the sun a few days, and then drawn off into five-gallon tin cans. The can from which the sample was taken has stood in an upper room, through which the pipe from a cookstove below passes. It was very white when taken, and remained so until a few months ago. I think it got moved too near the stovepipe for summer, and that has darkened it. It has never been candied. Please express opinion of sample. Why wait before extracting for it to get so thick that wired combs will break? I seldom break a comb, and never wire.

I have never had honey to sour, and always get the highest quotations. I have been in the business, in a small way, for over 40 years for myself. One year I had exclusive control of a mountain apiary belonging to another party, from which I secured 40 tons of extracted honey.

DELOS WOOD.

Santa Barbara, Cal., Oct. 24.

[Your sample came duly to hand. The honey is certainly very fine in body, color, and flavor. I never tasted any honey ripened by the bees that was better. I have before tasted artificially ripened honey that I considered the equal of any ripened by the bees. Where one is expert, has the proper appliances, a warm dry room, and a suitable climate, such honey can be made, and is just as good, and, what is of great importance, at a great saving of labor,

both of the bees in capping and of their owner in uncapping. Usually it is better for beginners to let the artificial ripening alone. Our senior editor's first experience was disastrous.—Ed.]

ANOTHER BLACK EYE FOR THE "GOLDENS."

Send me by return mail two untested Italian queens. Give us the good old-fashioned sort. I have had all I want of the goldens.

Corunna, Ind.

S. FARRINGTON.

S. S. K., Wis.—Wintering in upground repositories, as double frost-proof buildings, is the same as wintering in cellars. See "Wintering," on page 33 of our catalog; also A B C of Bee Culture.

B. H. G., Kan.—Sorghum molasses can be used for feeding bees, and perhaps will answer all right in your locality; but sugar syrup is far better. If the molasses is very thick, perhaps it had better be thinned with a little hot water before feeding. As you have the molasses on hand we would use it in preference to buying sugar for syrup.

W. H. P., Col.—Replying to your question as to whether sweet clover yields every year, I would say that no honey-plant gives nectar every season. All of them seem to have their off-years. Yet sweet clover, so far as I can remember, yields some honey every year; in fact, it seems to be more regularly visited by the bees every season than any other plant with which I am acquainted. Yes, stock eat it; but they have to learn to like it; and when they once acquire the taste for it they will sometimes browse it down in preference to any thing else. It is a biennial. It springs up the first year, but does not yield honey until the second season, and then is visited by the bees from that time until frost, when it is killed. See fuller particulars in regard to this in the A B C of Bee Culture, under the heading of "Clover."

D. S. G., Col.—The disease called foul brood attacks the larvæ in all stages of growth, and even the young pupæ in the cells of capped brood.

As to the difference between foul brood and chilled brood, the former has a yellowish-brown color and a glue-pot odor. The latter may have that color, but is more often grayish or black. The real distinctive difference is, that the grub dead from foul brood is ropy, while that from chilled brood is not. What I mean by "ropy" is that, when a toothpick is inserted into the

dead mass of an affected cell, the matured matter will adhere to the pick while it is being drawn out slowly, like spittle. The dead matter from chilled brood shows no such thing. The disease that we mention, that resembles foul brood, shows all the characteristics of foul brood with the exception that it is only slightly ropy, and it does not spread from one colony to another, but simply goes off by itself.

J. R. O., Iowa—The teaching of your scientific leader, to the effect that bees lose their instinct for storing honey, and gather only so much as will carry them through rains in certain warm portions of the country, is erroneous. There is a very slight shade of truth in it, but hardly enough to give it a passing notice. The fact is, bees gather two or three times as much honey per colony in hot climates as they do up north where the honey-flow is short and the winter season protracted. Where the honey-flow is continuous the bees will work right on continuously, and wear themselves out only to be replaced by new and younger blood that goes on doing the same thing. I said there was a slight shade of truth in the teachings of your leader. One or two have thought that bees grow a little lazy in the South; but real facts disprove it. Climatic influences, if they have any effect at all, require a much longer time to develop lazy bees. Your leader may be a scientific man; but the knowledge of a practical bee-keeper—yes, thousands of them—on this point, should have vastly more weight than any science he can bring to bear.

A. M., Ohio.—The Salisbury (or Lewis) beef-diet treatment, in brief, is this: First and foremost in importance is the washing-out of the stomach. This is done by drinking a pint of hot water an hour and a half before dinner and supper, half an hour before going to bed, and an hour before breakfast. No liquid food should be taken at any other time unless, perhaps, it is half a cup of tea after eating, and no cold liquid should be taken at any time. The patient usually starts by eating four or five ounces of beef—broiled; not fried or roasted. Mutton is allowed occasionally instead of the beef. To start on, it is better to grind the beef with an Enterprise meat-grinder. After the meat is ground (i.e., run two or three times through the machine), it should be made into a little meat patty, but not compressed, and should be held in the broiler over live coals, a gas or gasoline flame, until it is thoroughly cooked through; but be very careful not to overdo it, as it will make it indigestible. A small piece of toast, about as big as a postal card, dried clear through, is allowed. As soon the stomach can take care of it, a larger amount of meat is allowed; but care must be taken that you do not overeat at any time. If you can eat eight ounces, or even ten, and feel no inconvenience after it, all right.

For a while you will feel worse, and lose flesh; but if you persistently hold to the diet, in spite of what "good and reputable physicians" say to the contrary, you will come out all right, and your former enthusiasm and love for your work will come back.

The writer experienced just exactly the sensations you speak of; and he knows what he is talking about when he says you will feel better on the above regimen—beef and hot water.

Now in answer to your questions: It is far better to have your meals regularly; but take them irregularly if you can not take them otherwise; but it is absolutely essential that the hot water be taken at the intervals stated (viz., one and a half hours *before meals*), or it will do more harm than good. The "best round steak from the shoulder bone" was a misprint. It was corrected, but probably did not get into the number you had. The round steak should come from the flank. Yes, it is all right to wake up in the night and take a pint of hot water. At any time in the night when you can not sleep it will be found to be beneficial. During the day, drink the amount stated at the proper intervals, whether you *feel like it* or not. As to constipation, the meat diet seems to aggravate it at first, and it is often necessary to take a light physic occasionally, or, better still, wash the bowels out with an injection of warm water. We would strongly urge you to go to Dr. J. M. Lewis, Permanent Block, 176 Euclid Ave., Cleveland, if you wish to get the full benefit of the treatment.

R. H., Col.—If you are troubled with inaction of the bowels while on the beef diet we would advise you to take a mild physic, and a stronger one later on if necessary. The writer has used Park's tea to advantage; but another member of the family much prefers Garfield's, both of which you probably have in your drugstore. The success of the beef diet depends upon keeping the bowels open; but you must be careful or you will have what is known as "scouring," and the bowels may run off too freely, and it will be hard to bring them under control. This is characteristic of the meat diet for the first few weeks; but it does no harm; indeed, you will feel better after it. If you can not get either of the teas above mentioned, get about a pound of senna leaves and put a tablespoonful of them in a cup of hot water, and, when nearly cold, drink about half of it. If that does not produce action, take a little stronger dose next time. Don't get discouraged, but keep on with the diet, and, above all things, keep the bowels clear.

If you would like to have any of your friends see a specimen copy of Gleanings, make known the request on a postal, with the address or addresses, and we will, with pleasure, send them.

CALIFORNIA AS A BEE-KEEPING STATE.

THE QUESTION CAREFULLY CONSIDERED IN A
NUTSHELL BY ONE OF CALIFORNIA'S
EXTENSIVE AND PRACTICAL
BEE-KEEPERS.

[Although much has been written setting forth the real status of California bee-keeping, I know of nothing that boils the whole matter down any more carefully, conservatively, and fairly, than the paper read by J. F. McIntyre, of Fillmore, before the farmers' institute that was held in that State recently. From this paper I make a few extracts that I am sure our prospective tourists, or those who entertain an idea of some time making California their home, would do well to read carefully—not because it gives a discouraging view, but because it gives the situation fairly considered on both sides—not by one who has merely visited or been in the State for a short time, but one who has been there for years. Mr. McIntyre says:—Ed.]

I believe that the majority of bee-keepers, in Southern California at least, have their locations fully stocked with bees, and do not care either to buy or sell, or to induce others to bring more bees into their locations, which would overstock them and surely bring disaster to one or both parties occupying such field.

* * * * *

When all the conditions are favorable, California can produce the largest crop of the finest honey in the world, not excepting the famous thyme honey of Hymettus, the clover and basswood honey of the East, or the alfalfa honey of Arizona and Colorado; but during the last twenty years we have had these favorable conditions on an average only once in three years; or, to be more explicit, we have had seven good years, nine in which the bees made from ten to sixty pounds to the hive, and four years in which the bees had to be fed large quantities of honey to keep them from starving to death.

When only the large yields, ranging from 150 to 600 pounds per colony, are reported to the tenderfoot, he naturally grows enthusiastic, and concludes to endure bee-stings for a few seasons, and use the bee business as a stepping-stone to the banking business; but, oh how different in the morning, when he finds that we have such things as dry years, hot winds that destroy the prospects of a honey crop in three days, when he thought success was certain, to say nothing of the three bee-diseases—foul brood, dead brood, and bee-paralysis! and when he does secure the long-looked-for crop, and attempts to dispose of it, he finds the honey merchant and railroad company waiting for it with low prices and high freight rates. This applies to the sagebrush bee-keeping in the mountains of Southern California.

There is another section of the State, however, which is rapidly coming to the front as a bee country, and is not affected by dry years or hot winds. I refer to the alfalfa districts of Kern, Tulare, and Kings Counties. A neighbor who sold his bees to me, and moved to that section to engage in the bee business there, is well pleased with the change, and reports a profit of \$12 per colony for this season. Alfalfa honey is amber-colored, and not so fine-flavored as sage honey; but the advantage of making a crop every year more than compensates for the difference in price, which is always higher when the sage-honey crop is a failure.

In the northern half of the State few bees are kept, and a small amount of inferior honey produced; consequently, this section is not worth considering by the man or woman who wishes to make a specialty of bee-keeping.

Compared with eastern bee-keeping, California has some advantages and some disadvantages. Our warm winters enable us to winter our bees without having to carry them into the cellar in the fall and out again in the spring; a larger number of colonies may be kept in one apiary, which saves an immense amount of travel from one apiary to another; the average yield per colony, taking a number of years together, is a little higher—the yield of the Sespe

apiary, which is about an average location, being 7 pounds per colony per annum for twenty years.

Some of the disadvantages are: Lower price of honey, owing to distance from market, and high freight rates; dry years, which often kill more bees by starvation than die of cold in the East; most apiaries are located in the mountains, away from society, schools, and churches, and are lonesome places to live, especially for women, and consequently many bee-men are bachelors.

The disadvantages, however, may be somewhat modified. Bees can and should be fed in dry years in time to keep them from starving to death. The price of honey may be helped out somewhat if the bee-keeper keeps well on his feet financially, and is not obliged to sell as soon as his crop is harvested.

THE BEE-KEEPERS' CONGRESS AT ATLANTA; HOW TO GET THERE, ETC.

On December 4th and 5th 1895, there will be a general meeting of all the bee-keepers of the United States and Canada at the Cotton States Exposition Grounds, Atlanta, Ga. It is to be hoped that all bee-keepers will make a strong effort to be there from Western New York, Canada, Ohio, and Michigan. Arrange to leave home so you can reach Cincinnati Monday evening and take the Louisville & Nashville Railroad from Cincinnati at 7:30 P. M., reaching Nashville Tuesday morning. From Chicago you can leave at 5 P. M. via the Eastern Illinois, and reach Nashville Tuesday morning; via the other routes, you leave in the morning. From the Northwestern States, arrange to leave home so as to reach Chicago Monday, and Nashville Tuesday morning. From the West, arrange to reach St. Louis and take the Monday-evening train of the Louisville & Nashville Railroad, and reach Nashville Tuesday morning. From Nashville the train will run solid, and be a daylight ride to Atlanta, Ga., passing through all the famous battle-fields from Nashville through Murfreesboro (Stone River battle-field), and for miles in full view of and around the base of Lookout Mountain to Chattanooga, and from there through Ringgold, Dalton, Resaca, Kingston, Kennesaw, Big Shanty, and Marietta, to Atlanta.

Do not forget the route—Louisville & Nashville Railroad; Nashville, Chattanooga & St. Louis Railroad, and the Western & Atlantic Railroad, all coupon tickets. Agents can sell you tickets via the above route. Call on your home ticket-agent for exposition rates, and join the bee-keepers for Atlanta, and secure your tickets read Louisville & Nashville Railroad to Nashville. For information not obtainable of your home ticket-agent, address Geo. B. Horner, D. P. A., St. Louis, Mo.; J. K. Ridgely, N. W. P. A., Chicago, Ill.; Herman Holmes, T. P. A., Medina, Ohio; Jackson Smith, D. P. A., Cincinnati, Ohio; C. P. Atmore, G. P. A., Louisville, Ky. Send your names to A. I. Root, Medina, O. If you are going, so they will be here November 30. This is also the "Daisy Route" to Florida.

[Doubtless many of our readers have been much interested in the description of the great peach-orchards established by Hale Brothers, near Fort Valley, Houston Co., Ga. If they should make the trip to Atlanta it would be only a little further to visit this great plant, where such wonderful success has been recently achieved in growing the finest peaches ever produced in the State of Georgia. Several numbers of the *Rural New Yorker* during the month of October gave full particulars, with illustrations of this undertaking. Should it be my privilege to meet with the bee-keepers on the days mentioned above, I for one want to

make the trip to Fort Valley. Probably Ernest or myself will be on hand—possibly both. The only trouble will be in keeping us supplied with plenty of beefsteak.

IN his usual department in this issue, Doolittle gives some very interesting experiments on feeding back.

As previously announced, this edition numbers 15,000 copies. We shall be printing this number for the rest of the year.

IN order to make room in this issue, and still not crowd out the other matter, we add sixteen extra pages, to take in the symposium on wintering.

I TAKE pleasure in introducing to you "Sky-lark," or, rather, he introduces himself. See his "Pickings by the Way," just after Straws, in this issue. If in his soarings he "picks" some of us pretty hard—well, just score the editor, and he will try to get even with the lofty bird.

WE regret that the announcement of the next meeting of the California State Bee-keepers' Association did not appear in our columns in due time. In some way the copy was put with Ramble No. 143 (both written by the same person, on the same kind of paper), and we did not come across it till the last Ramble was put in type—too late to do any good. We write this to exonerate the secretary more than ourselves. The meeting takes place on the 18th and 19th of this month.

THAT EUCALYPTUS HONEY FROM AUSTRALIA
THAT WAS ON EXHIBITION AT THE
WORLD'S FAIR.

THE following, just received from Dr. Miller, will explain itself:

Dear Editor:—Can any one tell us what became of the fine exhibit of eucalyptus honeys at the World's Fair? One hundred and twenty-six two-pound glass jars of the various kinds were sent by the Hunter River Association from Australia, and the proper commissioner was requested to hand over the entire exhibit to Dr. Riley, to be placed in the museum for permanent exhibition at Washington. Dr. Riley also promised to send an exhibit of U. S. honey to be placed in the Technical Museum of the Australians. Unless very lately done, this promise has never been fulfilled; and in the changing of officers it may have been forgotten. Please tell us what can be done to help keep our credit good with our Australian brethren.

C. C. MILLER.

Marengo, Ill., Nov. 11.

I may explain that the above was called forth by a letter to the doctor, received from the sec-

retary of the Hunter River Association, Mr. R. Patten, asking him in regard to that honey. He had already written the Department of Agriculture at Washington, and also to Mr. Frank Benton, without reply; and now he appeals to the doctor to help him out. We will send a marked copy of this to the Department of Agriculture, Washington, and we hope the proper person will be able to give us the information desired.

BEE-JOURNAL EDITORS AND THE BEEF DIET.

THE editor of the *Canadian Bee Journal*, I regret to say, has been very much "under the weather"—so much so that the two last issues of his journal have been delayed some. But he has (or had up to Oct. 9) gained strength enough to be back at the editorial helm a few hours a day. A year ago, you will remember, I was placed almost in a similar position; but, I am happy to say, thanks to the beef-diet treatment which I am still taking, I am just about out of the woods. I feel better than for years; indeed, I am putting on good solid flesh—anywhere from *one to four pounds a week*—the latter being made during the last 7 days. Besides all this, I feel as if I had a mountain of strength and a big stock of reserve force. I propose to keep right on with the diet until I get a constitution that will not be affected by "weather" or any thing else.

I have been trying to get Bro. Holtermann on the same treatment, and he has partially consented to come and go with me to see Dr. Lewis, of 176 Euclid Ave., Cleveland, O. He is too valuable a man to be laid up thus by the "weather."

By the way, the editor of the *Review* says all the bee-editors have been ailing to a greater or less extent, and it looks as if he were right.

If this thing keeps up I shall be preaching beef diet to all of them. I succeeded in getting A. I. R. on to it, much to his benefit, as you know; and, after my earnest solicitation, F. A. Salisbury, that bee-keeper and supply-man of Syracuse, N. Y., went on to it, and at this writing he has been on the diet some five weeks. Oh, yes! Dr. Miller and family are taking it too.

VISITORS AT THE HOME OF THE HONEY-BEES;
THE ALFALFA FIELDS OF THE WEST, ETC.

WE have just had the pleasure of a visit from two prominent bee-keepers—one from the extreme eastern coast, and the other from the far, far away West. Mr. Francis Danzenbaker, of Washington, D. C., called in the interests of the new hive which he has just gotten out. It has a single-story brood-nest, something after the style of his last year's hive, with some little added improvement. The surplus-apartment remains practically the same. But he will have something to say concerning this in Trade Notes later on.

Mr. W. K. Ball, of Reno, Nev., came up with a carload of honey—that beautiful alfalfa that is pronounced by every one who tastes it the finest-flavored honey in the world. It is beautifully rich and thick—so thick, indeed, that it is fairly waxy. In answer to my question as to what kind of season he had had, he said it had been rather poor with him for the last two years.

“Rather poor?” said I; “and what was your average?”

“About 150 lbs., extracted.”

Neighbor Chase, who stood by, turned to me with a smile, and said that, if he could average 50 lbs., to say nothing of the 100, in good years, he would be satisfied. You see, Mr. Ball depends upon alfalfa that is watered by irrigation. The problem of wet and dry seasons is one that they do not have to contend with. The amount of moisture is regulated artificially by man, and you might almost say the flow of nectar from alfalfa, lasting for three months, is regulated in the same way.

A few years ago Mr. Ball thought the locality could not be overstocked; but in later years a good bee range there is pretty well stocked with bees already. But there are portions of Colorado (Brush, Morgan Co., for instance), so Mr. Ball tells me, that sell for from twenty to forty dollars an acre, with water, that would do just as well. Here they get three cuttings of alfalfa per season. It is as fine a grain country as he ever saw.

Mr. Ball owns some 300 colonies, and is using exclusively the eight-frame Dovetailed hive containing Hoffman frames. While here I asked him if these frames gave entire satisfaction. He replied that they did. In answer to the question whether he was ever troubled with burr-combs, he said not, provided he kept ahead of the bees. I showed him at the office some self-spacing frames with metal projections; but he shook his head, and said he preferred to have the wood instead.

When I told him there was a sort of demand for a self-spacing frame with metal projections, and something that can be separated a little more easily than the Hoffman, he said he *wanted* his frames to be stuck together so that he could handle his colonies by the hive. He admitted that queen-breeders might prefer a frame that would require no prying.

The super that he uses is the regular Dove-tailed containing section-holders. The wide wooden separators and the keying up are features that he valued. As Mr. Ball produces tons and tons of honey every season, sending it east by the carload, his testimony along these points was valuable.

The bees he uses are ordinary leather-colored Italians, and hybrids. He has been trying five-banded bees and Carniolans. The former were too cross, too much inclined to rob, and gather-

ed only about half as much honey as the other bees. The Carniolans were gentle, but swarmed altogether too much.

A VISIT FROM BERT COOK, SON OF PROF. A. J. COOK.

A COUPLE of weeks ago a young man dressed in the garb of a bicyclist was brought up to the office by one of our men, and introduced to the writer as Mr. Cook, of Owosso, Mich. He knew my father quite well, he said, and had taken especial interest in my wheeling-tours among bee-keepers, as reported in these columns. I was busy at the time, but asked him to take a seat, and prepared myself to extend to him the ordinary courtesies of a brother-wheelman. It is true he was introduced to me as “Mr. Cook, from Owosso, Mich.,” but as there are a good many Cooks I thought nothing of it; and in the course of our conversation he made a number of inquiries in regard to A. I. Root, gardening, and especially in regard to potato-growing. I had to confess I knew little or nothing about it, and that he would have to see A. I. R., who, I said, was over home taking supper. He politely excused himself and said he would like to call and see him later if agreeable.

There was a gentlemanly and scholarly bearing about him that impressed me favorably, and I said to myself, “Who can he be?” as he left. So a few minutes afterward I called over to the house and told father there was a potato-man over there who seemed to be well up in the art of potato-growing, and that he knew Terry and himself pretty well, and that his name was Mr. Cook, of Otsego, Mich. “Otsego,” said father, “I don’t remember of any Cook there.” I had got Owosso and Otsego mixed up, and so he did not recognize the identity of the name or locality. An hour or so afterward, he came over to my house, a comical smile playing on his face, remarking, “You are a bright one, you are. That young man you were telling me about was Prof. Cook’s son.”

“Prof. Cook’s son!” said I, surprised.

“Yes, indeed. Come over and see him. We have all been enjoying his company.”

“Well,” I said, “he could hardly have thought I was extending him ordinary courtesy to let him go off to a hotel for his supper in that way, and he a son of Prof. Cook. I will go over and apologize.”

It seems he had told me his father was A. J. Cook; but I presume I did not hear him say so; but I was made to feel that no apology was necessary, for he had had a “real good Dutch supper” at the Germania House.

Mr. Cook, Jr., although a college graduate, and a man of more than ordinary attainments, I should say, thinks farming is none too humble a calling for him. He is at present running a farm belonging to his father, near Owosso, Mich., somewhat after Terry, and he is making a great success of it. He is a warm admirer of

Mr. Terry himself, and after leaving here he was expecting to make him a short call.

He had wheeled it, prior to coming here, all the way from Lansing, Mich., to Columbus, O.; and how much farther south I do not know. But he had already covered several hundred miles during raw, wet, rainy weather. Indeed, one of his runs was made during a heavy rain; and, as he expressed it, he was just as wet as if he had been dipped into a cistern. He caught cold, having no dry clothes to put on after the end of the run, but was recovering from it at the time of his visit at Medina.

He was in a hurry, and could stay with us only over night and a little while during the next forenoon. Before he started off again I could not resist the temptation to catch him with the camera, and the result you see above.

BERT COOK.

As the morning was a little raw, A. I. R. had his overcoat on, with the collar turned up around his neck. Mrs. A. I. R. did not intend to be caught in the picture; but she had come out on the porch to say good-by to Bert, and of course just in time to "get shot." She expressed a wish after the picture was taken that her own figure should be erased. The position of A. I. R. as he stands there is one that is very characteristic and natural when he is outdoors giving directions to his men. His own wheel, you see, leans against the house, in its usual position; for where the wheel is you may be sure A. I. R. is not far off, because he will not nowadays walk even from the house to the factory, a distance of less than 500 feet, as it is so much cheaper and easier to ride. Yes, in going 'cross-lots over the gardens he just simply hops on to the wheel and makes it transport him to every part of the plantation, and he "gets there" too.

N. B.—I obtained Bert's consent to use this picture for print. At first he objected; but

when I told him that the general reading public had a claim on him through his father, he at last consented.

THE LANGSTROTH SYMPOSIUM.

FOR our symposium on Langstroth, notice of which has been before given, we have already received communications, one from Edward Bertrand, editor of *Revue Internationale*, of Nyon, Switzerland; one from C. J. H. Gravenhorst, editor of *Illustrierte Bienenzeitung*, Wilsnack, Germany; and one from W. F. Clarke, former editor of the *American Bee Journal*; Prof. Cook, of Pomona College, Cal., all testifying, without regard to country, their high appreciation of Mr. Langstroth, and his services to bee-keepers over the whole world. These and more will appear in the last number of the year.

Since writing the foregoing, I find a very extended and well-written sketch of Mr. Langstroth and his work in the *British Bee Journal* for Oct. 31. Among other things the editor, Mr. Cowan, says: "All readers of Langstroth on the Honey-bee have been charmed by its loftiness of style and the purity of its diction."

"PROFITABLE BEE-KEEPING" is the title of a series of lessons for beginners now running in *Southland Queen*, published by the Jennie Atchley Co., Beeville, Texas. So far as I have examined them they seem to be practical, correct in teaching, and especially adapted to bee-keeping of the South. Indeed, the *Queen* is growing better as it grows older.

By the way, Mrs. Jennie Atchley seems to think I am trying to "sit down on the five-banders, and can't," because I admit that a neighbor finds them to be good workers, and that we have had a couple of good colonies ourselves. As I have said before, I have only given both sides—the good as well as the adverse reports. If the former considerably overbalance the latter, I am sure it is not my fault. If it had been the other way I should have been sounding their praises as loud as any one.

SINCE writing the item in another column regarding sick bee-editors, I am happy to state that Mr. Holtermann is here, and is looking quite well. He says he has gained 11 lbs. As he has a good deal of institute work, necessitating much travel, it will be impossible for him to take diet in the winter; but he is going to take, not tea, but *beef* with me to-day, cooked *a la* Salisbury.

WE regret to announce the death of Mr. John Huckle, "Secretary of the British Bee-keepers' Association, and for many years connected with the business department of the *British Bee Journal*, who passed away at his home at Kings Langley, Herts, on the afternoon of Friday, Oct. 25."

OUR HOMES.

Brethren, the grace of our Lord Jesus Christ be with your spirit.—GAL. 6:18.

Last Sunday evening it was my privilege to listen to a sermon by the Rev. A. T. Reed. It was under the preaching of Bro. Reed, through God's providence, that I was first brought to the light of the gospel of Christ Jesus; and I presume the very tones of his voice will evermore appeal to me in a way that no other voice can or will. Dear friends, where is the good pastor who brought you from the darkness of unbelief out into the light? Do not forget him. If he is so far away that you can not go and hear him preach, send him some little reminder of your gratitude and kind memories, say once a year at least. It will do you good, and it will do him good. But I must not digress.

Bro. Reed is now an evangelist. He may come into your neighborhood. If so, do not neglect to hear him and give him an encouraging word. I told him at the close of his talk that I was going to take his sermon for one of my Home Papers. It would not be exactly his sermon, after all, because it will be after A. I. Root, although the original thoughts for the most part belong to A. T. Reed.

The subject was grace; but in contrasting it with law, a good part of the sermon might be said to concern *law* as well as *grace*. A young lady once asked him to define grace. He thought a moment, and then replied that the Bible itself gave about the best definition of grace he had ever seen. It is in the 15th chapter of Luke. The younger son became impatient of parental restraint, and begged for his portion, and went away, as you all know, and spent it in riotous living. When his money was all gone, he came home again, as you all know. We do not know how he looked; but probably his face showed the marks of his dissipation and excesses. Very likely, with blood-shot and bloated face, and ragged clothing, he decided to go back to his father. Perhaps he recognizes how kind his father had been, even giving him the money that he did not deserve (and which was not justly his own), to go off and do as he had done. He had come to himself sufficiently to decide that he is no more worthy to be called a son. He is simply going to petition, as one of the hired servants. You know the outcome. The broken-hearted old father saw him when he was yet a great way off, and he did not even wait for him to come up. He ran to him, and broke the boy down completely by falling on his neck and kissing him. The poor wretched son manages to say, in broken sentences, "I am no more worthy to be called thy son." The father does not heed this at all, however. He calls to the attendants who have followed after him, and bids them bring the very best things to be had in the house; they take off his tattered and dirty clothing; give him the *best* robe, put a ring on his hand, and shoes on his feet; then they go and get the fatted calf; "for this my son was dead, and is alive again; he was lost, and is found." Not a word is said about his past delinquencies which he had vainly tried to confess; not a word is said in regard to the probability of his going off again on just such a another "spree." It is all forgotten and *forgotten* in the joy of having back again the one whom he had long mourned for as dead, or worse than dead. This, my friends, is a picture of grace. It is a very good picture indeed of the saving grace of the Lord Jesus Christ and his gospel.

Thousands are ready to say, "This is my religion; this is what I believe in. Gentleness and kindness will save the world." Hold on a little. Let us turn back to the 15th chapter of Numbers. Here we have a little story that is often quoted by those who would ridicule or make sport of the Holy Bible. They say that a man was put to death simply for gathering a few sticks on the sabbath. In fact, we read, in the 36th verse, "All the congregation brought him without the camp, and stoned him with stones, and he died; as the Lord commanded Moses."

You will notice that it ends up by saying, "As the Lord commanded Moses." I confess this passage has always been a hard one for me to understand. At the time of my conversion I was obliged to put it aside, with a good many others of a like character, hoping and trusting that, at some future time, the Lord would see fit to give me light on the subject. Bro. Reed told us this was an example of *law*. A school-teacher finds it necessary to forbid certain things. Some rebellious pupil will often be found who will go straightway and break the rule almost as soon as it is made; then the rest of the school look on and say, "What is the master going to do now?" It is a critical time. What *shall* the teacher do?

As Mr. Reed was telling the story my mind ran quickly back to the first school I ever taught. When I commenced I believed in grace, and succeeded in gaining the respect and good will of at least the most of my pupils, and they were making excellent progress. Toward the close of the term, however, whispering and talking became so prevalent in that country school that I knew something would have to be done. I talked with my pupils good-naturedly, and plead with them earnestly, and finally, as a last resort, gave notice that, after a certain time, I expected all *communications* during the hours of study would be stopped. A young man of nearly my own age, and my superior in weight and muscle, whispered to his next neighbor almost as soon as I had laid down the rule. I took him to task. He admitted he had broken the rule, and finally told me *then* and *there* that I was "not man enough" to teach that school, anyhow. The most unpleasant part of it was that he had told the truth. I was obliged to *agree* with him—at least to this extent: *Before* that, I had not heretofore shown enough *manliness* together with grace and mercy. Boys and girls sometimes grow from childhood to maturity in a very short space of time. In the few minutes I stood before my defiant pupil I made some amazing *steps* in growth from boyhood to manhood. Of course, a good many of the pupils were on my side; but the whole school was mentally *taking my dimensions*. That young man, I presume, will remember that day to the last day of his life, and I *certainly* shall. I kept on with the school, and by request taught a month longer than the usual winter term. Not only was the whispering stopped from that day forward, but I was a different man, and a *better* man (in many respects) from that time on. I was *fore-ed*, as it were, into a crisis in my life. I hardly need tell you, dear friends, that our whole nation is going through just such experiences almost every day and every hour. If our laws can be held up and enforced by grace and mercy, all right; but if not, then hard, unyielding law, with its iron bands and prison bars, must do the work.

Complaint is often made that parents, teachers, and even officers of the law, punish one offender, while they let another go, when both have committed the same offense. This is

true, and it is right. Suppose a teacher finds it necessary to make a rule, as I have before illustrated. Some defiant boy breaks the rule as soon as it is made. He looks the teacher square in the face, perhaps with a defiant smile. Such a boy is called up, and severely punished. Somebody reports that "Johnnie" also did exactly the same thing. The teacher knows both boys, and their habits and dispositions. Johnnie comes forward, with his poor little face puckered up in agony at the thought of the punishment. He finally bursts out crying, and confesses his fault, at the same time that he also confesses another fault. He was not *listening*, and did not hear what the teacher had said. The teacher replies, perhaps, something like this:

"Johnnie, from what I have known of you I could not for a moment believe it possible that you willfully and *defiantly* disobeyed me. We can all see by your looks and manner that you are sufficiently punished already. You may go to your seat; but for my sake, as well as your own, be careful to *listen* in the future, when your teacher is talking."

In the family circle the father often represents law, while the mother represents grace and mercy. Very likely God intended it should be thus. Both are right and proper. Some boys once accosted another boy, who had had a good bringing-up. Perhaps the conversation was something like this:

"Jimmie, we are going to have some fun to-night. Come and go with us."

"But," says Jimmie, "I have to be at home at 9 o'clock every night, you know."

"Oh! fudge, Jimmie. Who is going to stand about nine o'clock after a boy gets to be as old as you are? You just come along with us this once. Why, we are going to 'paint the town red' to-night. Sooner or later you are going to be a man and judge about these things yourself. Just tell the 'governor,' as I told mine, 'scolding don't hurt none; whipping don't last long! kill me if you dare. I am ready; come ahead.'"

Jimmie should not have stood and listened to such talk, but, like many another boy, I fear he did. I need not tell you all that was said. Most of you know something about it already. The consequence was, he went with the rest of the boys. He did not get back at ten o'clock nor eleven; and then when he did go, the question was, how to meet *law*. He climbed up on top of the woodshed, and then pulled off his boots. You know how it is yourself, most of you. After a long time he got the window up, almost without noise, and felt a little relieved to hear Law snoring loudly. His father was sound asleep. He got into bed without making a bit of noise, or pretty nearly that. But just as he was closing his eyes to go to sleep he was startled by hearing footsteps on the stairway.

"Why, that can not be father," said he to himself; "no, for I still hear him snoring. Oh! it must be mother." And then he decided to pretend he was asleep. She came up to his bedside so carefully that he hardly realized her presence until he felt her gentle kiss on his face; and then, in spite of her, two or three hot teardrops trickled down across his forehead. Not a word was spoken. She went back as she came up. A few nights after, the boys invited him again; but Jimmie shook his head.

"Oh! you caught it from the governor, did you?"

And then they commenced their taunts and jeers. Jimmie evidently did not see fit to tell them his reasons for refusing. Not long after, however, his father died. Then they came after him again.

"Well, Jimmie, the governor is dead and gone now, and you are a man to act for yourself and do as you please. Come out with us, and let's have some more fun."

Jimmie straightened himself up a little. He too had been growing within a few days.

"Boys, do you think I have been at home every night at nine o'clock, during all these months that are past because I *fear*ed my father? You are mistaken. I stayed at home and behaved myself out of respect to my good mother; and now that father is dead and gone, and she is left alone in the world, if it needs the last bit of breath there is in my body, and the last bit of strength I possess to defend her, and avoid hurting her feelings, either directly or indirectly, that breath and that strength shall be freely given, even if it is only a feeble payment of the great debt of gratitude I owe to her for what she has done for me."

That kiss and those teardrops on that memorable night were more potent with Jimmie than any punishment the father had power to inflict. Alas! boys are not all Jimmies.

I have mentioned to you how often in my travels I am called upon to ask a blessing at the table. A great many times the friends say, "Mr. Root, will you say grace?" I believe the word "grace" is more used in the South than it is here at the North. But what a beautiful thought! grace before meals! Let us take an example if you please. A laboring-man comes home to dinner. The poor overworked wife is springing about here and there; in fact, she is sometimes a good deal slyer than a girl of 16, even though she is past 40. The husband says, "Dear me! have we got to wait for dinner now, when I have not a minute to spare?" Then he adds, "Why can't you do something to keep that baby from yelling like that?" Just at this time Johnnie comes home from school, and happens to get in his father's way, and he gives him a cuff. Then Mary does something that a child ought not to do, and she is sent off crying, in a similar way. By this time the wife has hastily got the meat on the table. The father sits down, cuts off a huge chunk, and crams it into his mouth. Dear friends, you can fill out the picture yourselves. If you have not witnessed just such scenes, may be some portions of the story may come home to you.

But we will suppose this man and his wife have been attending the revival meetings. The husband has been converted. He comes home to dinner as before, his work crowding, but he can not sit down as he used to do, for now they say "grace" before meals; yes, and *grace* all through the meal and after the meal. He is tired and hungry, and feels petulant; but he does not give way to it. The baby is crying. In a minute the strong arms of the father have lifted it up. Then the father's strong earnest "grace" and good will have driven away the tears, and the baby is laughing with delight. The wife comes in with the meat as before, and what a change has come over her poor tired self!

"Dear wife, did you ever see a brighter or handsomer baby?"

There are still marks of the teardrops down the baby's cheeks, but he is crowing with delight. Johnnie come in and says he is next to the head at school. "Well done, Johnnie," says the father, and he gives him an approving pat on the head. Then Mary has something pleasant to tell. The children help to bring the chairs to the table, then the father carries the baby with one arm while he helps bring in the things from the kitchen with the other; and finally all are ready to sit around the happy board. Now, I do not know exactly what

sort of a blessing John asks before they commence their meal; but you may be sure there is grace in it, no matter what the words may be. If his saying grace is after my own fashion, his words would probably be something like this:

"O Lord, we thank thee for this pleasant and happy home. We thank thee for these our dear children. We thank thee for health and strength, and for good appetites, and for this our daily food. May it strengthen us that we may be helpful, one to another, and that we may be self-sacrificing; that we may have grace to use our strength so that selfish feelings shall be put down, together with all that is evil; and may we uphold all that is good and noble and pure, for the sake of the dear Master, our Lord and Savior Christ Jesus. Amen."

Some of you may say that all this takes a good deal of time. My friends, it really takes less time than I have been telling it, for all soon learn to help. If the parents set an example before the children, of bearing each other's burdens, when all go to work cheerfully to help things along, instead of hindering, then time is being *saved*. Besides, this very cheerfulness and bright hopefulness helps digestion to such an extent that all will be better fitted for the duties of the afternoon, and more work is accomplished—oh dear me! *before* supper-time—than if each pushed ahead for self and nothing else, and hardly took time to eat a meal and eat it properly. Of late I have been, by the doctor's orders, taking a full half-hour, or sometimes three-quarters, for each meal, principally because every thing is so thoroughly chewed before it is swallowed, instead of washing down the food with drink at meal-times. Well, I am greatly a gainer, and the time thus taken to say grace before our meals, and to get all the family together "decently and in order," is certainly *saved*, oftentimes, *many times over*, before the day's duties are done.

A great many people, you know, call the Old Testament "law," and the New Testament "grace;" and some go so far as to keep the one and reject the other. I have given you one illustration of law from the Old Testament. Just read about Ananias and Sapphira in the 5th chapter of Acts, and you will have a striking illustration of the need of *law* as well as *grace*, in the New Testament. It was just in the beginning of the Christian church; at the very outset, hypocrisy, deception, and falsehood had crept in. The very life of the new church depended on prompt and vigorous measures; and this terrible illustration was given us that it might stand through time and eternity as a warning to all who would undertake to make religion a cloak.

It is true that the New Testament is mostly taken up with the coming of the Savior to this world. "For God so loved the world that he gave his only begotten Son;" and it is also true that the message of that only begotten Son was peace on earth, good will to men. As we have it in the first chapter of John, "The only begotten of the Father, full of grace and truth." The Savior's mission was one of grace. While he did not annul the law or do away with it, his work was *particularly* a work of grace. But he fulfilled the law by his mission of mercy and grace. Almost the only time when he used any means that even approached severity was when he took occasion to drive the money-changers out of the temple. The Old Testament is law in one sense; but if we had to deal with law, and law only, we should all be lost, every one of us, for we are all sinners; and it is here that this mission of grace comes in; or as that beautiful hymn expresses it—

Jesus paid it all—all to him I owe;
and as I approach this part of my subject a great number of those old familiar hymns well up in a way that seems as if the writers must *surely* have been inspired when they wrote them. For instance:

Just as I am, without one plea,
But that thy blood was shed for me.

You see the sinner does not depend upon his good deeds nor upon his clean and faultless life. He acknowledges in the outset that there is no hope in *that* direction. Our only hope is through the blood that was shed, and the grace so freely given for us. And then, again, comes in that old hymn that I used to hear my father sing just as far back as I can remember. He was converted, if I remember rightly, at a revival meeting, and perhaps it was my good fortune to hear some of those hymns of praise welling forth as a spontaneous outburst of a new-born soul:

Oh, to grace how great a debtor
Daily I'm constrained to be!

How many, many times it has occurred to me that my father must have passed through much the same trials I have met—much the same that I am meeting day by day! How wonderfully expressive that word "debtor" comes in! Again:

Let thy goodness, like a fetter,
Bind my wand'ring heart to thee.

We naturally associate the word "fetter" with something disagreeable; but when we think of being fettered by the *goodness* and *grace* of Christ Jesus, then well may we burst forth, "O glorious fetters!"* Once more:

Prone to wander—Lord, I love it;
Prone to leave the God I follow.

I do not know how it is with the rest of you, friends, but these two lines tell the history of my life better than any thing else ever told it. With sadness and sorrow, with humiliation and shame, I acknowledge that I am *still* prone to wander; and what shall be done, not only for me, but for all others like me? Here we have it:

Here's my heart; oh, take and seal it—
Seal it for thy courts above!

That is all we can do; and, oh glorious thought! it is all we *have* to do—all we *need* to do. If our hearts are in the Savior's care—if they have been placed in his keeping—if his loving *seal* has made them safe, the work is done, through life and through eternity.

Let me now close with that wonderful verse from the first chapter of John—a verse that, it seems to me, I have never appreciated and understood before as I do now at the close of this talk:

And the Word was made flesh, and dwelt among us
(and we beheld his glory, the glory as of the only begotten of the Father), full of grace and truth.

There is a class of people, as you know, who claim that they do not want grace or mercy. All they ask for is *justice*. By the way, it just occurs to me that the friends I meet in the county jail are the ones who oftenest make this claim. I do not know that I have ever heard anybody, however, plainly declare he had never broken any of God's laws—even the best men among us. The most faultless Christian, our leading evangelists, whose lives are *comparatively* clean and unspotted, would not

* You will remember that Jimmie's companions supposed he was fettered by the law of his father. There were fetters, it is true, that kept Jimmie; but they were fetters of grace—his mother's prayers and anxious solicitude. Yes, the tears that were shed when she supposed him to be asleep were the fetters that held his "wandering heart."

dare to claim this. If, then, there is no salvation by clinging to hard, unyielding law, it must come through the grace of Christ Jesus.

For there is no other name under heaven given among men, whereby we must be saved.—ACTS 4:12.

BATTLE CREEK, MICH.

I have heard of people being *half* baked; but I do not know that I ever heard any mention of their being *twice* baked. Huber says the zwieback (*tsueebok*) that our family are all so fond of simply means twice baked—from *zwei*, two, and *backen*, to bake. You see, Huber is studying German. Well, this delicious bread, which is getting to be so popular of late, is called zwieback because the bread is baked in the usual way, and then sliced up and baked again; and this last baking should be a slow process, occupying several hours; and to get the best and most wholesome product, not only should every bit of moisture be expelled from the bread slices, but the starch should be mostly converted into dextrine; then the patient, if he is suffering from impaired digestion, should eat it without drinking any liquid whatever. I complained to Dr. Lewis that it took me so long to finish my meal. Said I:

"Doctor, why can't I moisten it with a little hot water? it takes so everlastingly long to eat even a little piece if I chew it as you direct, until it is a soft and creamy food; that is, when the juices of the mouth have to furnish a lubricant."

He replied something as follows:

"That is just exactly what I want you to do. Take plenty of time to eat your meat and zwieback both, to masticate them to completion and mix them with the secretion which nature produces on purpose. We want the digestion to be carried as far as possible while the food is in the mouth, and thus relieve the worn-out or impaired stomach and bowels."

By the way, it has been suggested that the reason why Carlsbad, Germany, has such a reputation as a health-resort is that the people there subsist mostly on their famous zwieback.

The Battle Creek folks manufacture three kinds—that made from white bread, rye bread, and from whole-wheat flour. Dr. Lewis gives the preference very strongly to the whole-wheat flour. By the way, we have a flour-mill just five miles from here, where they have recently put in an apparatus for making whole-wheat flour. After testing a great many kinds of health foods, I am forced to decide that bread (or, rather, zwieback) made from whole-wheat flour, comes the nearest to beefsteak of any thing I can get. If you are suffering from indigestion, get some of this whole-wheat flour, and have some good bread made, without any sugar or baking-powder. Slice it up, and dry the slices, as I have told you. If you want a sample of the very best, get some of the Battle Creek product. You can get a small sample by mail. May be you will decide, as we have done, to buy it rather than to take the trouble to make it yourself. They buy a special brand of wheat, the best that can be got. It is most carefully cleaned, and then ground with the very best apparatus for making the whole-wheat flour. The bread is then made by machinery of the very best improved kind. All

the kneading and hard work is done by a steam-engine. It is then baked in a coke-furnace that does it just to a dot. Then the loaves are sliced up by appropriate machinery, and baked again by being placed on large trays of netting. These trays revolve slowly so as to be several hours in getting once around; and during these several hours, each tray is exposed to just the right temperature to dry it to the best advantage. The result, instead of the ordinary dry crust, as some might call the zwieback, is a crisp and delicious dry bread that crushes in your mouth like the most delicate crackers or wafers; and one of the nicest things about the zwieback is that it will keep indefinitely if you will only keep it *dry*. If the weather is damp, and you can not keep it in a dry place, give it another baking, say once in several days. In this way it may be kept indefinitely. I understand they ship it clear down to Florida.*

You may be at first inclined to call their food products expensive; but please remember that every particle of moisture is expelled, so you do not pay any thing for *water* as you do in buying canned goods, loaves of bread, fruit, or almost any thing else. Again, the cooking is all done on a large scale by appropriate machinery. If you want to get along in your housekeeping, without a hired girl, or a limited amount of help, using food already cooked, it is a very great saving, especially when it results in saving your wife from laborious housework. Again, it is most wholesome. The same may be said of their delicious grain product called granose. In making this, the very best and nicest choice wheat is steamed and parched, the parching being done with steam as well as the cooking, if I have got it right; and this cooking process is carried on several hours, so as to make every portion of the grain as easy to digest as thorough cooking can make it. Then it is passed through rollers that spread the wheat grains out thin like Saratoga chips on a small scale. Last, it is thoroughly dried, so it will keep like the zwieback, indefinitely. This is a delicious food to eat raw, without any cooking whatever. I have just had a *taste* of it when moistened with milk, and it seemed to me the very embodiment of something both delicious and nutritious. I think Huber agrees with me, by the way in which he manages a bowl of granose and milk. But I am for the present forbidden the use of milk.

There were so many machines and so many

[There are quite a few people who have found that they can not eat oysters; at least, oysters and crackers as usually served do not agree with them. Let all such substitute zwieback for the ordinary oyster-cracker of commerce and note the result. If you think our ordinary crackers are made of good healthy materials, let some of them get old, and see what they smell like; then give zwieback the same treatment. At the usual retail prices I know zwieback costs a little more than the crackers. In our market oyster-crackers retail at 8 cts., while the Battle Creek zwieback is 10. But I think you will agree with me that a pound of the latter contains a good deal more food than a pound of crackers, besides being ever so much more wholesome. Again, if the housewife has plenty of time, and not much to do, she can manufacture the zwieback so it will not cost nearly as much per pound as the crackers. Please remember the best kind of wheat flour costs less than 2 cts. per lb.; and the cost of every thing required to make the bread or the zwieback, if you choose, aside from labor, should not be more than 2 cts. Of course, you can buy crackers when there is not time to make bread. But it is a good deal cheaper, and ever so much healthier, to let good home-made bread take the place of crackers in the family; and I think you will agree with me that zwieback, made of whole-wheat flour, is more toothsome, besides being *ever so much* more healthful.]

processes going on in the way of cooking, baking, and drying, that I found myself quite unable to take it all in during my brief stay; and I am just now feeling as if I wanted to go back to Battle Creek and look the thing all over again. But I must not spend all my time in talking about that cooking-factory, even if it is an exceedingly interesting matter to me. At this stage of health I am gaining flesh at the rate of two or three pounds a week, with an appetite all the while for a good deal more than I allow myself to eat. Yes, I have learned, among other things, that overeating *must* be guarded against, even on the diet of pure beef, especially when the patient is allowed also a little zwieback or granose, or something equivalent. The Battle Creek folks have a great printing-establishment. By the way, what do you think of a great building containing 280 printers—yes, *printers*—who neither drink, swear, nor use tobacco? Now, I presume there are quite a few type-setters who read GLEANINGS; but they need not feel hurt at what I have said, for I know something of the habits of the average printer, especially in our great cities. Well, these Battle Creek printers not only abstain from all these things I have mentioned, but, if I am correct, they use neither tea nor coffee, and for the most part are probably vegetarians, and eat only *two* meals a day. What effect did it have on them? Well, I used my eyes in that great dining-room so thoroughly that I did not know but some of the men and women would feel hurt; but even with the vegetarian habits, and with only two meals a day, they were about as healthy, happy, and nice-looking a lot of people as I ever saw in my life. They seemed to have a "right smart" of an appetite for their dinner, between two and three in the afternoon; but I did not think any the less of them for that. It just did me good to see them help themselves to plateful after plateful of the provisions. And I began to wonder to see them all have such vigorous appetites until I remembered they had had nothing since about eight o'clock in the morning, and expected nothing to eat again until the same time the *next* morning. They took plenty of time to eat their food, and there was lots of chatting and good-natured merriment going on. Take it all round, you may find as much fault with the Advent people as you can; but after it is all said and done, you will have to admit that they not only have a model establishment, but that they are a model *people*.

□ It seems almost out of place for a man of my age, especially after some of my teachings, to say any thing about the good-looking women at the sanitarium; but when I tell you to put particular emphasis on the *good* I think it will be all right. Yes, I think I never saw any handsomer women anywhere in my life. And this calls to mind the fact that not one out of the several hundred employed there wears a *corset*. If I have not told you before my opinion in regard to corsets, you can probably guess what it is. And then, again, if I have made no mistake there was not a woman in that crowd who wore ear-rings or even a *finger-ring*. In fact, I am not sure that they wear jewelry at all. Dear me! if all the jewelry in the United States of America were converted into money, or, better still, if we had had the money before it was ever *invested* in jewelry, there would be no need of the present destitute state of affairs in our mission work in foreign lands, to say nothing of the need of efficient *teachers* in our own America.

There are something like 600 people employed in and about the sanitarium, and there are chapel services twice every day—once in the

morning and once in the afternoon; and the help, I believe, as a rule, are expected to attend at least one of these services every day. A great number of them take part, either in reading the Bible, repeating texts, giving brief experiences, or brief sentence-prayers. It takes a good deal of time. Yes, so it does; but the helpers are *paid* for their time while attending the services, just the same as while at their work, and the management have found it to pay.

Friend Keck gave me some valuable points right here, and yet they are not so *very* wonderful after all. When I suggested that, among such a crowd, there would certainly be some who would be tricky or dishonest, he said they had found by years of past experience that *prevention* is better than cure. Whenever any one of their number begins to show a disposition to evade or avoid chapel services, the probability is that he is straying away from the fold, and the right committee is notified to look after him. When this system is carried out, there is almost no such thing as a defaulter or forger. The man is stopped long *before* he gets into the depths of *crime*.

"But these people must be terribly strict," you say. Yes, they are. Before one unites with them, and consents to change his usual Sunday to Saturday, he must have pretty *strong convictions*. It made me think of Gideon's band we had in our Sunday-school lesson recently, as you may remember. Under God's direction, Gideon sorted out the very cream of his great army. The Battle Creek people seem to have sorted out—well, let us say some very faithful, earnest, devoted men and women who are banded to carry on their work.

Although the institution possesses immense wealth, its *members* can not get rich very fast. They all work on small salaries. For instance, the nurses, of which there are several hundred, get only five or six dollars a week; but if they go out through the city of Battle Creek and elsewhere to take care of patients, they get from ten to twenty dollars a week. The profit goes to build up the sanitarium. But this sanitarium has never paid any dividends, and never *expects* to pay any. Money, labor, and every thing else, is for the glory of God—at least, this is the way I got it from friend Keck; and if I am wrong, somebody who reads GLEANINGS can doubtless set me right in regard to it.

To be Continued.

DOCTORING WITHOUT MEDICINE.

HOW TO MAKE THE MOST DELICIOUS AND
TOOTH-SOME PIES, AND PIES THAT
HELP DIGESTION INSTEAD OF
IMPAIRING IT.

Through all the long weeks and months of my pure-beef-diet experience, perhaps I have longed for apple-pie more than for any other one thing. Sometimes I could actually have gone away and cried because I could not have any, especially when Mrs. Root brought forth some of her own making, with their brown, crisp, flaky crust and appetizing flavor. The doctor, however, was inexorable. He said it was a depraved appetite that was calling for the very thing that had got me into my past troubles. I knew he was right, because I found by many trials that a piece of pie after dinner was what upset me entirely, especially if I partook of the rich and greasy pies so often found when one is away from home. Well, now, for my discovery. At the present time I am eating about 1½ ounces of sirloin steak at each meal,

with greater appetite and zest than I ever ate anything before in my life. I verily do believe. Of late I am allowed with this meat diet say about one ounce of zwieback, such as I have described; and, by the way, one ounce, if it is made right, is a pretty good slice of bread. I am also allowed a piece of butter about as large as will lie on a teaspoon without heaping it up very much; and for the past few weeks the doctor has permitted me to make some explorations in the line of testing different kinds of vegetable food. For instance, when I insisted that I could digest corn-meal mush when thoroughly cooked a long while, he told me to try it—eat a small sauce-dishful for breakfast only—not any other vegetable food during the day. The one experiment satisfied me that the doctor was right. Corn meal is by no means the grain to choose, if you want one easy of digestion. Bread made from whole-wheat flour is ever so much better, but the zwieback is still better. Rice, when cooked a long while, is perhaps as easy of digestion as any thing else unless it is the zwieback. Some of the patients eat green peas, without trouble—that is, when the peas first begin to ripen, and none are old and hard. The green peas did not do for me at all. They were even worse than the corn meal. I need not tell you of other experiments made; but my final conclusion was that the doctor knew his business, and had a better knowledge of my particular case than I had myself.*

I have always had a great fondness for baked apples; but the doctor felt pretty sure I had not got to the point yet where I could manage them, and one or two tests showed me he was right. A few days ago, however, it occurred to me that a little baked apple, or plain applesauce without sugar, would go well with my granose, and not do harm. Mrs. Root made some plain sauce for me out of rambo apples, cooking

*Perhaps I had better acknowledge right here that I have had an attack of my chills since I have been on the meat diet. After I had been experimenting on corn meal, green peas, and baked apples, it happened I was called to a church conference in a remote part of our county. It was in a small town where there was neither hotel nor meat-market. I did not discover this until just at meal-time, after a prolonged afternoon session. I thought I would ask one of the waiters to get me some meat of some kind; but there was a greater crowd to dinner than they expected, and everybody was hurried and worried; so for once I ate a promiscuous dinner of chicken-pie, soft fresh biscuits, cookies, etc. There did not seem to be any help for it unless I intruded my "peculiar notions" (as people might call them), and so I submitted. The next morning I had sore throat; then I was called away from home again, ate two more "regular meals," and got my digestive apparatus completely out of tune, took one of my old severe colds, had to be bundled up with fur cap and overcoat, and finally became so hoarse a part of one afternoon that I could not speak a word, and for the first time in my life I had to write on a piece of paper what I wanted to say. Nobody could read my hasty writing (not even Mrs. Root herself), and I tell you I was in real trouble. Sick, sore, weary, cold and chilly, I could not speak a word. I finally decided to go back to the doctor and confess my shortcomings. He said it was just what I might have expected, and that it was entirely the result of my backsliding and getting away from my regular meals and habits. But he finally told me to "be of good cheer;" for if I would get right back to clean ground meat, and nothing else, for four or five days, all would be straight. At the diet-house Mrs. Ferguson gave me new courage by saying she had seen the doctor get his patients out of similar troubles again and again. "Why," said she, "he just 'cleans the cold right out of them' by his doses of hot water, and strict meat diet, and they are all right again in two three days." It took me about a week to get back into the straight path from which I had strayed away, and it left me perhaps a little sadder, and I trust a little wiser, for my experience.

them several hours. About as much of this sauce as one ordinarily gets in a piece of apple-pie was given to me in a saucer. Instead of putting my spoonful of butter on the meat I spread it over the warm apple-sauce. Then I sifted on about half an ounce of granose. An ounce of granose makes a great heaping saucerful, as you will notice if you try it. Well, this made my delicious pie. The butter furnishes the shortening, and the granose the crust. Surely there was never made by housewife or anybody else a more crisp, flaky, toothsome, and delicious pie-crust than the granose formed. With my spoon I mashed it down into the melted butter and sauce. I have now eaten a similar dish perhaps half a dozen times, and it agrees with me to perfection. The other half-ounce of my granose is sprinkled in the gravy, with my sirloin steak; and if the combined culinary art can get up a more delicious meal—that is, from my point of view—I have never yet found it—meat, fruit, and grain combined. If your apples are made into sauce, without sugar, they preserve the distinctive flavor of each variety; and the fact that I can now eat the different apples that are talked about, in the way I have described, and enjoy them as I never enjoyed them before, fills me with gratitude and thanksgiving.

Yesterday afternoon, when I awoke from my nap, almost before consciousness was fully restored, the thought came into my mind—"Praise God, from whom all blessings flow;" and I greatly enjoyed singing it out loud; and not only the words but the sentiment welled up from the bottom of my heart.

Some of Dr. Miller's friends felt troubled because I got down to 110 lbs.; so they will feel glad to know that to-day, Nov. 9, I have got up to 117½ lbs., and I feel happy, strong, and well, every hour of the 24, and especially the half-hour or fifteen minutes before dinner-time.*

The gluten mush I spoke of in the last issue is tiptop; but it is a very powerful and concentrated food, and does not seem to answer for every meal quite as well as the zwieback. All these things, however, are nice for a change.

FORTY POTATOES OF THE CRAIG SEEDLING.

Above we give you the picture mentioned in our last issue. The Craig potato is remarkably fine-shaped, a flattened oval, with eyes very nearly level, so that it is easy to pare; no knobs

* To-day, Nov. 13, I have got up to 121½ lbs.

nor projections; almost always of large size. Outside it is a little on the reddish line; but when cooked it is almost white—a little yellowish white, perhaps. While the quality is not equal to the Freeman, it is fully as good as any of the large strong-growing potatoes. I have never myself seen any of them where the vines died before they were killed by frost; consequently none of ours, very likely, gave us as fine a quality of potatoes as where they ripened up of their own accord. Possibly our plan of heavy mulching with coarse manure has much to do with keeping them growing as they do; but I shall, at least so long as I have such good success, hold fast to the mulching plan. Just think of it! the most of the work is done before your potatoes are planted. Before they are quite out of the ground we go over them with the smoothing harrow, and we use this harrow again after they are up just a little. If the weather is favorable, then we use the Breed's weeder; and by the time they have been cultivated, say two or three times with the Planet or Iron Age cultivators having a good many fine teeth, the tops begin to cover the ground so they are ready for the mulch. We have them planted such a distance apart that the horses and wagon straddle the rows. One man pitches off the coarse manure while another pitches it under the foliage or between the hills. If you have a pretty good soaking rain after you get this mulch in place, your potatoes are pretty sure to be safe so far as drouth is concerned. If rank weeds push through the mulching, pull them out by hand. Our experience is, however, that, with the Craig potato, the vines soon cover the ground so thoroughly but little care or tending is required after you put on the mulching.

Several who have reported speak of the missing hills; and I am forced to conclude this may be a fault with the potato. Next spring, however, we are going to try to have every eye started before it is planted; that is, we will plant no pieces until the eyes have started sufficiently to make it pretty certain, and then we shall have a full stand. Here is a report from away down in Missouri:

FORTY-SIX POUNDS OF POTATOES FROM ONE POUND PLANTED.

The two pounds of Craig potatoes I bought of you last spring were cut to one eye pieces; planted when I planted early potatoes; vines very rank, but dead before frost. Yield, 92 lbs. of fine large potatoes, the best I raised this year. My Freemans did not come up to my expectations.

JOHN GEARHART.

Princeton, Mo., Nov. 6.

Yes, friends, we know the Freeman ordinarily does not give the great yield that many other potatoes do; but for the present, in our family, the Freeman leads them all in quality. We had some baked for breakfast this morning. Several other kinds were put in so as to compare them with the Freeman. If you want a baked potato to be nice, you must be on hand when they are just ready to come out of the oven. The Freemans would break open with the contents, so dry and floury they would almost shake out of the peeling.

AT THE RATE OF 120 POUNDS FROM 1 POUND PLANTED.

Last spring I received by mail from you one-fourth pound of Craig potatoes. They were cut to single eyes, making 14 which were planted one in a hill, in moderately strong garden soil. The tops died down two or three weeks before frost, and I dug 30 pounds of them. I don't know much about how potatoes

ought to yield, but it strikes me that raising potatoes at the rate of 120 pounds to 1 planted is doing pretty well. They were nearly all of good size, but only one of them weighed a pound. Orlin, Mo., Oct. 28.

D. B. THOMAS.

Well, well, friend T., your report, it seems to me, beats every thing heretofore; at the rate of 120 lbs., from one pound planted, it is away ahead of even Maule's Thoroughbred. But yours had a whole season to grow in, or nearly the whole, as it is a late potato; and probably you took a little more pains than the ordinary field culture given the Thoroughbreds by friend Terry.

I bought one pound of Craigs of you last spring. I cut them one eye on a piece, and put two pieces in a hill, making 18 hills all told. Only about half of them started. I think they had been frosted, as they were black, more or less on the inside. Have you had any complaint on that score? I dug them a few days ago—just 40 lbs. of old whoppers. I tell you—no small ones at all, only in one hill, where there was a dozen or more from the size of a pea to that of a hickorynut. The bugs ate them some, and they blighted, but not as bad as other varieties all around them. Maggie Murphy is very similar in color and shape, but earlier, and blighted the worst of any, and is not quite as large. There was no sign of any scab on the Craigs.

E. MANNING.

Jacksonville, N. Y., Oct. 21.

The Sir William potato, advertised in this issue, is a very nice table potato, in addition to its many other good qualities. I had a bite of a large nice one this morning, so that I know whereof I speak.

In giving the price of granola, in our last issue, it was, by mistake, put at 20 cts., when it should have been 10 cts. in bulk or 12 cts. in 1-lb. cartons, and whole-wheat wafers should be 12 cts. per lb., instead of 20 cts.

EARLY OHIO POTATOES.—ANOTHER LOT.

For several weeks we have been sold out of Early Ohios, but have just now secured a fine lot of about 200 bushels. We can now furnish them, both firsts and seconds, as heretofore advertised; namely, \$1.50 per barrel of 11 pecks for firsts; 75 cts. per barrel for seconds, so long as the seconds hold out.

MAULE'S NEW EARLY THOROUGHbred POTATO UNDER GLASS.

On page 819 I told you we had received a pound of the above by mail. The pound consisted of three medium-sized potatoes. A half of one of them was cooked as a sample. The rest were cut to one eye, and planted 7 inches apart in our best lettuce-greenhouse across the way. Exhaust steam was turned under the bed so as to give bottom heat; and to-day, just 20 days after they were put in the ground, we are delighted to find they are sprouting nicely. Two of them have already burst through the ground. The 2½ potatoes made just 28 eyes. Now, then, we are going to see what can be done in the way of raising potatoes under glass, started the latter part of October. We propose to move them further apart as fast as they get crowded.

I am very sorry that quite a few have understood that we give a pound of these potatoes for renewing your subscription instead of sending us a new subscription. My object in making this big offer was to get GLEANINGS into families or localities where it has not been before; and our five barrels of potatoes that cost us so much money would be gone in no time if we gave a dollar's worth of potatoes to every one who renews for 1896. We stand quite

ready to return the money to all who think there has been any unfairness about our offer. In this issue there will be found some exceedingly liberal offers for simply renewing, and nothing else.

OUR NEW LOW-PRICED SASHES FOR COLD-FRAMES, HOT-BEDS, AND MOVABLE-SASH GREENHOUSES.

With the above we give you a cut of our new light hot-bed sash, both made up and in the flat. It all goes together with screws, and can thus be shipped very cheaply in the flat at low rates for freight. We are using these sash every day right along with others that weigh twice as much, and cost as much again; and we should much prefer the light cheap sash, even if the heavy ones were offered us at the same price. For prices see page 825, Nov. 1.

THE FUMA, OR BISULPHIDE OF CARBON.

The advertisement of this, which appears in our present issue, is surely the greatest thing in the way of an insecticide that has yet been discovered. We have repeatedly mentioned its wonderful property of killing the weevil in beans and peas, even before they have eaten through the seed. Recent investigations by our experiment stations and others have shown that it is the cheapest and most effective remedy for almost every insect, or animal pest that afflicts the farmer or horticulturist. We used to pay 40 or 50 cts. a pound for the drug; but it is now offered in quantities for less than one fourth that price. There should be no excuse now for having insects, rats or mice, in our houses, barns, cellars, granaries, or anywhere else. It is not often that we give so much space toward helping an advertiser; but this is a recent product of unusual merit.

ALFALFA HONEY.

Since our last issue we have received from Reno, Nev., a carload of choice alfalfa honey, consisting of over 800 24-lb. cases of comb honey, 104 cases of two 5-gallon cans, and 28 cases of six 1-gallon cans of extracted honey. The larger part of the comb honey has already been sold. It is very white and choice. As the honey-flow was cut off suddenly by frost, there are a good many unfinished sections. These we have put into cases by themselves, and should be glad to hear from any who can use such honey in considerable quantities. All the honey, even in these unfinished sections, is very thick and heavy, and as delicious to the taste as the finest honey ever gathered. We offer choice comb honey at 16 cts. per lb. Lots of 9 cases, crated for safe shipment, by freight, 15c. The No. 2, or unfinished sections, 3c per lb. less. The extracted honey in 5-gallon cans we offer at 8c per lb. by the case of 2 cans; 7½ in 2 case lots; 7c in 5 case lots or over.

White-sage honey at the same price. Clover and basswood, and Michigan willow-herb honey, ½c per lb. extra.

Alfalfa honey in 1-gallon cans, at \$1.05 each; \$6.00 per case of 6; two cases, \$11.30; 5 cases, \$26.50.

CARLOAD ORDERS.

We have received, during the past few days, orders for four carloads of bee-keepers' supplies. One is for export to Sydney, Austr.; another, consisting chiefly of sections for export to England, and two carloads for Barteldes & Co., Denver, Colo. In these two cars are 8000 shipping-cases—sufficient to case 90 tons of comb honey. We have already sent to Colorado this year a good many thousand cases, and the bee-keepers there have evidently secured a good crop of honey this year. We are also expecting daily an order for a carload of goods to Portland, Oregon, for Buell Lamberson, our agent for Oregon and Washington. We have the assurance of a carload order from McClure Bros., Las Cruces, New Mexico, and recommend all our readers in that section of country, who are in need of supplies for

next season, to communicate with these parties, who can save you money because of what they save by getting the goods out in car lots.

ON TO ATLANTA.

Ask your ticket-agent for tickets to the Cotton States Exposition at Atlanta, Ga., via the Louisville & Nashville and Nashville, Chattanooga & St. Louis Railroads. This is the old soldiers' route during the late war, passing through Murfreesboro (Stone River battlefield), Tullahoma, Bridgeport, and for miles in full view and around the base of Lookout Mountain; also the famous Moccasin Bend to Chattanooga; thence over the Western & Atlantic Railroad to Atlanta. The schedules are as follows: The last mail leaves Cincinnati at 11:30 A. M.; arrives at Louisville at 2:57 P. M.; Nashville, 8:58 P. M.; Leaves St. Louis 7:52 A. M.; Evansville, 2:12 P. M.; Nashville, 9:10 P. M.; Chattanooga, 1 A. M. Arrives at Atlanta 6:50 A. M. The Cotton States Flyer leaves Cincinnati 7:30 P. M.; arrives at Louisville 11:14 P. M.; Nashville, 6:50 A. M. Leaves St. Louis at 7:35 P. M.; Evansville, 1:25 A. M. Due at Nashville 7:10 A. M.; Chattanooga, 11:50 A. M. Arrives at Atlanta 4:00 P. M. The Atlanta special leaves Cincinnati 5:30 P. M.; Louisville, 9:30 P. M.; Nashville, 2:40 A. M.; Chattanooga, 7:30 A. M. Arrives at Atlanta 11:25 A. M., and is a solid train from Cincinnati to Atlanta. All trains have elegant day coaches and Pullman's finest sleeping-cars. HERMAN HOLMES, T. P. A., Medina, Ohio. JACKSON SMITH, D. P. A., Cincinnati, Ohio. C. P. ATMORE, G. P. A., Louisville, Ky.

CONVENTION NOTICE.

The annual meeting of the Illinois State Bee-keepers' Association will be held at the Statler Hotel, Springfield, Nov. 19, 20. The Odd Fellows of Illinois hold their grand encampment, beginning on the 19th, and we have it from their committee on railroads that they have secured open rates of a fare and a third—that is, a round trip ticket—is to be purchased at starting-point, anywhere in the State, for 1½ fare. The special meeting of our association will be held at Chicago, at the New Briggs Hotel, Jan. 9, 10, 1896. As this is the occasion of the National Cycle Show, we can get reduced rates to that meeting. Further particulars later. JAS. A. STOVE, Sec.

Bradfordton, Ill.

For \$350.00. One hundred 2-story hives complete for comb honey; bees and hives in good order. Inquire of **A. LEYVRAZ, Francis, Fla.**

KEMP'S MANURE-SPREADER.

13 YEARS ON THE MARKET. IMPROVED FOR 1895.

SPREADS any kind of manure in any quantity to the acre, and does it better than hand work, even if a man spends ten hours on what the machine will do in two minutes. Sent to any responsible party subject to approval, that will furnish satisfactory references or rating of responsibility. Illustrated catalogue free. **Largest and oldest manufacturers of manure-spreaders in the world.**

Advantages of Bee-Escapes.

No sweat steals down the heated cheeks and aching back of the bee-keeper as the result of standing in the hot sun plugging, blowing, smoking, and brushing bees; no time is wasted in these disagreeable operations; and no stings received in resentment of such treatment; the honey is secured free from black or even the taint of smoke; the cappings are not injured by the gnawings of bees; and robbers stand no show whatever. If there are any broken burr-combs they are cleaned up by the bees inside the hive, before the honey is removed. **Leading Bee-keepers use the Porter Escape,** and say that without a trial it is impossible to realize the amount of vexatious, annoying, disagreeable work that it saves. The cost is only 20 cts. each, or \$2.25 per doz. As in the past, this escape is manufactured by the Porters, but **THE A. I. ROOT CO.** are now the exclusive selling agents for this country. Order of your dealer or of

THE A. I. ROOT CO., Medina, Ohio.

Read what **J. I. PARENT, of CHARLTON, N. Y.,** says—"We cut with one of our Combined Machines last winter 50 chaff hives with 7-inch cap, 100 honey-racks, 500 broad frames, 2,000 honey-boxes, and a great deal of other work. This winter we have doubled the amount of bee-hives, etc., to make, and we expect to do it all with this saw. It will do all you say it will." Catalogue and Price List free. Address **W. F. & JOHN BARNES, 545 Ruby St., Rockford, Ill.**

When more convenient, orders for Barnes' Foot-Power Machinery may be sent to

THE A. I. ROOT CO.

Please mention this paper.

W. O. Victor, of Wharton, Tex., took

45,000 Lbs. of Honey in 1894.

He offers Italian Queens—good, old-style honey-queens—untested, first order, to any address, at 50c each. Also bees in any quantity; 450 colonies to draw from. **Root's goods constantly in stock.** Prices to suit the times. Buy near home, and save freight.

The Sir William Potato.

The photo-engraving above shows a peck basketful of **Sir William** potatoes; 14 tubers weighing 15 lbs. In my deld few weighed less than $\frac{1}{2}$ lb., and some ran as high as $1\frac{1}{2}$ lbs. Some of the good points of this remarkable new potato are as follows:

1. It is a **very heavy yielder.** Its yield this year, as far as dug, is about 200 bushels per acre on my rather thin soil, with extreme drouth from planting until August 6. Ten other good varieties with same chance are averaging about 100 bushels per acre. It is a thrifty grower from the start, and resists bugs and drouth and blight better than most other kinds.

2. It is **ideal in shape, color, and cooking quality.**

3. It is **medium-late.** Planted by May 1 it will usually mature before Sept. 1, **in time to follow with wheat;** a great advantage to many growers.

4. If the seed is large, and cut to one or two eyes (as I recommend for large seed), practically **all of the tubers** will be of marketable size. For three years on my farm it has shown a **less per cent of small potatoes** than any other variety.

I believe it to be the best all-round medium-late potato. I have tested it now three years before offering a pound for sale, and am ready to vouch for the above good qualities from personal trial. I have **never yet put my name to an unsuccessful thing and I guarantee satisfaction** to all who buy seed of me, cut it carefully to one or two eyes, plant it on good potato soil, and give it thorough tillage. I offer the seed at the following prices, which I think are **lower than so new and so valuable** a variety was ever offered before.

REDUCED PRICES.

[In new sacks or new largest-sized apple-barrels, f. o. b. at Hudson.]

FIRSTS, single bushel, \$1.10; 2 bushels, \$2.00; single barrel, \$3.00; 10 barrels, \$25.00.

In all cases it is better to order in barrels. I advise strongly against sacks, as the tubers chafe and bruise, and are liable to theft by exchange for common varieties in transit.

ORDER PROMPTLY to secure seed, as the demand is strong. All paid orders received up to December 31, or until the supply is exhausted, will be shipped early in April without extra charge, if received too late to ship with safety this fall.

Send orders to **The A. I. ROOT CO.** or to

W. I. CHAMBERLAIN, Hudson, Ohio.

PREMIUM LIST--CONTINUED FROM PAGE 834.

Dodecahedron Paper-weights.

Several years ago we made a special importation from Germany of 1000 of the beautiful glass paper-weights of which the above is a very poor representation. Nothing would be more appropriate for a bee-keeper, as it illustrates the mathematics of the honey-cell to perfection. It is such a beauty that anybody will be pleased and delighted with it. No matter which way you turn it, you will be charmed by new beauties. The above cut gives the actual size. When we found it in Chicago it was retailing at 50 cents; but buying 1000 of them we got them at a figure that enables us to sell them at 20 cents each, or 6 for \$1.00; one dozen for \$1.80. By mail, 3 cts. extra on one; 12 cts. extra on 6, or 20 cts. extra per dozen for postage, and packing to prevent injury. We will send one free postpaid for a new subscription to GLEANINGS with \$1.00; or for a new subscription, with your own renewal, with \$2.00, and 5 cts. for postage, we will send two.

Peerless Flour-Bin.

There are a number of flour-bins on the market, of various styles. This one possesses special merit. Some kind of bin is a necessity for keeping flour neat and clean. The cut of the Peerless shows the can cut away to illustrate the manner in which it works. The connection between the crank on the side, and the revolving piece in the bottom over the sieve, is a heavy coiled wire spring, making the mechanism very simple and strong, and easy to operate. A finger projects from the revolving disk, to keep the flour stirred on to the sieve. This bin, instead of being hung up like the Tyler, stands on a table or shelf, and the flour is sifted into the drawer from which you empty it as needed. Price, each,

crated for safe shipment, \$1.75. A crate of 6 for \$9.00. Price of one Peerless bin, with GLEANINGS, one year, \$2.50.

Tyler's Flour-Receptacle.

A Much-needed Household Convenience.

This is the most convenient arrangement for flour that we have ever seen. It holds just a 49-lb. sack of flour. It is to be hung on the wall just above your table. When you want some flour simply place your pan under it, open the lid on the bottom and turn the crank and you get your flour already sifted. It is simple, neat, and effective, and not expensive either. Price \$2.00 each, crated ready for shipment, or given

free for 8 subscribers, with 8.00.

THE WORLD'S EDUCATOR.

This game is a perfect treasure-box of knowledge and fun. It asks and answers the most difficult questions, and is equally adapted to both old and young. Amusement and education are most happily combined; 72 questions and answers on each card, and ten cards go with it. When the knowledge on these is exhausted more can be obtained. The box is handsomely lithographed. Size 15x7 inches. Price \$1.00. Postage extra, 25 cts., if sent by mail. Given for 4 subscriptions, with \$4.00, and 25 cts. extra to pay postage.

Iron Plane. At first glance you might take it for a toy plane; but if you try it on a board you will find it is a plane in reality. They will sharpen a lead-pen oil beautifully, trim up a wood-cut or electrotype, take the corners off a rough box, reduce the width of a board, and do it all in a workmanlike and finished manner; and when they need sharpening, the bit is taken out or adjusted securely, by simply turning a single screw with the finger and thumb. Price 15 cts. By mail, 6 cts. extra, or sent free postpaid for one new subscriber, and \$1.00.

ROGERS' SILVER-PLATED WARE.

The silver-plated ware we offer on this page is warranted to be equal to any thing made. In fact, the manufacturers claim that they will strip more silver than any other goods made, and represented as the same grade. Our prices, too, are lower than are generally made on goods of equal value, and we think you will find very few opportunities to get the same class of goods so low. The fork shown at the right, is silver-plated on nickel. It is sectional plate—that is, triple plated on the three points, where the wear comes, and costs no more than the triple-plated steel forks. Nickel silver is a much superior base to plate than steel, and these forks will outwear the triple-plated steel forks for that reason.

Round Medium Knives, triple plated on steel, with Round Medium Forks, sectional plate on nickel silver, same as described above, \$3.50 per dozen (6 knives and 6 forks); postage extra, 36 cents. Either **knives or forks alone** will be \$3.50 per dozen. Postage on knives, 44 cents per dozen; on forks, 30 cents per dozen.

Dessert, or Tea Knives, triple plated on steel, \$3.40 per dozen; \$1.70 per one-half dozen.

Dessert Forks triple plate, on German silver, \$3.50 per set of 6; or \$7.00 per dozen. Postage, one-half dozen, 10 cents.

Tea-spoons, triple plate, on German or nickel silver. Tipped pattern. Price \$3.50 per dozen. Postage, 10 cents extra per dozen.

Dessert Spoons, same as above. Price \$6.00 per dozen. Postage, 20 cents extra.

Table-Spoons, same as above. Price \$7.00 per dozen. Postage, 25 cents extra.

Tea-Spoons, single plate, on nickel silver. Price \$2.50 per dozen. **Table-Spoons,** \$5.00 per dozen. One-half dozen of any of these at dozen rates.

Butter-Knife, triple plate, on steel. Price 35 cents each. Postage, 3 cents extra.

Sugar Shell, triple plate, on nickel silver. Price 60 cents each. **Single plate,** 35 cents. Postage, 2 cents extra. If you order the above by mail, send 8 cents extra with each order, to register the package. We will not be responsible for the loss of unregistered mail matter.

Each subscription to GLEANINGS, accompanied by \$1.00, will count as 25 cents toward the price of any of the above articles of silver ware, provided at least half are new names.

TEA AND TABLE SPOONS.

We have these in all grades, from 5 cents up to \$5.00 a set for teas, and from 10 cents up to \$3.50 for tables. He who can not suit his needs from this list must be fastidious indeed. Remember, that the same number of table-spoons of the same grade cost just twice as much as tea-spoons; or, in other words, 6 table-spoons are the same price as a dozen tea-spoons.

Tinned Iron Tea-Spoons, 5 cents per set of 6; postage, 4 cents extra. These are excellent for picnics, where, if you lose them, the loss will be slight.

Tinned Iron Table-Spoons, 10 cents per set of 6; postage, 7 cents extra.

Tinned Steel Tea Spoons, 10 cents per set of 6; postage, 6 cents extra.

Tinned Steel Table-Spoons, 20 cents per set of 6; postage, 12 cents extra.

These are as strong as the best spoons, and resemble so nearly the triple-plated silver spoons that you could hardly tell them apart at first glance. They are tipped pattern.

Hartford Silver-Metal Tea-Spoons, 60 cents per set of 6; postage, 6 cents extra.

Hartford Silver-Metal Table-Spoons, \$1.20 per set of 6; postage, 12 cents extra.

German silver contains 18 per cent of silver, and the rest is alloy. This Hartford silver metal contains 25 per cent. These spoons are all the way through alike, and always wear bright. We have also dessert spoons and forks of this same metal as follows:

Hartford Silver-Metal Dessert-Spoons, 90 cents per set of 6; postage, 10 cents extra. **Forks** same price.

For still better spoons, see Rogers' silver-plated ware. To get any of the above goods as premiums, each subscription, sent in with \$1.00, will count 25 cents toward the price, provided they are at least half new names, and postage extra if sent by mail.

TABLE AND CARVING KNIVES AND FORKS.

Knives and Forks, Fancy double bolster. We have several styles, in ebony and cocco handles. Above cut

shows only one style. Finely finished. Usual price of these goods is about \$1.50 to \$1.75 per set. **Our price, \$1.00 per set.** Postage, 30 cents extra per set. Sent free for **4 subscribers**, with \$4.00, and 30 cents to pay postage.

Knives and Forks, nickel plated. These are made of steel, then coated with tin, and then nickel plated. They very much resemble the triple-plated silver knives and forks, and wear for years as bright as silver. Price, per set of 6 knives and 6 forks, \$1.50; by mail, 36 cents extra. Given free for 6 subscribers, postage extra.

Carvers for Thanksgiving and Christmas Dinners.

Swell-Handled Carving-Knife and Fork. This is the greatest bargain in the whole list. It has swell cocoa handle, capped and bolstered. This pattern of knife and fork can not be bought by dealers in cutlery from the manufacturer for less than \$1.10, and you will not find them retailed for less than \$1.50; yet we have bought a quantity from a man who had several cords of them, which he bought with a large stock at ruinously low prices. Our price is only \$1.00 per pair; or steel included for \$1.35; postage extra, 15 cts. on carvers, and 10 cents on steel. Given free, without steel, for 4 subscriptions, postage extra.

Bread-Knife, 8-Inch, a first-class knife. Price 35 cents. Postage, 8 cents extra. Sent free, postpaid, for 2 subscribers, and \$2.00.

Bread-Knife, 9-Inch Blade, rosewood handle: an excellent slicer. Price 50 cents. Postage, 8 cents extra. Given for 2 subscribers, with \$2.00, and 8 cents for postage.

Butchers' Steak-Knife. This is a tremendous big slicer; handle 5½ inches long, and the blade 12 inches, and 1½ broad. This makes an excellent bread-knife; and, in case of a combat with burglars, it is big enough to use as a short sword. It is made of best forged steel, and cost about 96 cents to produce it. They were bought among other goods at a bankrupt sale, and we offer what we have at 75 cts. each; 15 cents extra if sent by mail. We can not get any more when these are gone. Given for 3 subscribers, with \$3.00, and 15 cts. to pay postage.

Corrugated Bread-knife.

I presume all who have tried it agree that, for cutting bread, especially fresh bread and cake, nothing is equal to a knife with corrugated (or saw-tooth) edge. The Christy and Clauss knives have had a large sale. Both of these have a straight blade with corrugated edge, and it is not so easily sharpened as a straight edge. The knife we offer overcomes this difficulty and still retains the corrugated edge. Because the blade is corrugated when it is ground with a straight bevel on one side, it makes the cutting edge corrugated, and accomplishes the desired result. We are also able to offer these knives for less than the others. We will give one free for one new subscriber to GLEANINGS, with \$1.00, and 5 cts. to pay postage, and you may offer the rest of this year free to the new subscriber. If you send your own renewal also, you may omit the 5 cts. postage, and we will send you postpaid.

An Aluminum Thimble.

This is something that will not rust or tarnish. It is so light you would not know it was on your finger by its weight. It is very tough, and will wear almost indefinitely. Nothing could be more desirable to give to wife or daughter, or your best girl. We will sell the thimble at 6c. postpaid, or 5c. with other goods, 5c. per dozen. The bread-knife at 25c postpaid; or with other goods, 20c each; \$2.00 per dozen.

Nickel Alarm Clock.

The adjoining cut shows our Early-riser alarm-clock. It is a marvel for the money. Only 75 cts., just half what we used to sell a similar one for. By mail, 15 cts. extra. Given free for 3 subscriptions and 15 cents extra for postage.

CARPET-SWEEPERS AT TWO-THIRDS REGULAR PRICES.

Ladies' Friend, Price \$1.50.

These are two of the most reliable sweepers made. The Ladies' Friend has two drive-wheels, while the Goshen has four. The latter therefore runs much easier. Mrs. Root has used a Ladies' Friend for 10 years, and does not want any other kind. The Goshen, you notice, has a rubber band around it to prevent it from marring the furniture should you run against it. No housewife who has carpets (and who has not?) should be without one

Coshen Sweeper, \$2.00.

of these sweepers, especially when they cost so little. You have no idea how much it lightens the labor of sweeping, to say nothing of the saving to your carpets. I don't know of a woman who has once got used to a good sweeper who would be without one for almost any price. The Ladies' Friend will be given for 6 subscribers, with \$6.00, and the Goshen for 8 subscribers, with \$8.00. They must be sent by express or freight alone or with other goods.

Home Repairing Outfit.

THE WHOLE KIT
OF 39 ARTICLES

WITH GLEANINGS
ONE YEAR \$3.25.

THE HOME REPAIRING OUTFIT NO. 1, PATENTED OCT. 8, 1895,

Consisting of the 39 first-class tools and materials shown in cut. Regular price, \$3.00. Sent with GLEANINGS one year for \$3.25. A new subscriber, with your own renewal and \$3.85, secures this outfit.

Home Repairing Outfit No. 2 is the same kit with the harness and soldering tools left out. Regular price \$2.00. With GLEANINGS one year, only \$2.50. A new subscriber sent with your renewal and \$3.10 secures outfit No. 2.

All these tools are full-sized; practical, neat, and cheap; not mere toys. They enable any person to do his own half-soleing, boot, shoe, rubber, harness, and tinware repairing.

Our improved Iron Lasts and Standard are one of the handiest tools you can have about the place. The Standard on this Outfit is made on the extension principle—that is, it can be used standing up at a bench, or on the floor while sitting in a chair. For use on a bench, the extension on top part of the Standard is omitted, making the height about 13 inches; while for floor use it can be instantly attached and the height adjusted to about 20 inches, making it just right for the lasts to be held between the knees when sitting in a chair, the base of the Standard resting on the floor.

The Iron Lasts are four in number, smooth and solid, 4, 6, 8, and 10 inches long, thus enabling one to half-sole all sizes of footwear. They are attached to the Standard by the use of a thumb-screw, which holds them in a perfectly rigid manner, so that they can not bound off or shuck around, as in the case of ordinary outfits.

The Sewing-clamp is attached in the same manner, and this fact alone renders it the most practical clamp on the market. The jaws are thrown open mechanically by a coiled spring on the bolt. It can be used for filing saws, and in many other cases where a vise would be necessary.

No. 2 American Typewriter.

A durable machine which does very nice work more rapidly than you can write with a pen. Our price \$8.00, including GLEANINGS one year free. A typewriter is already a necessity in business requiring correspondence of only a moderate extent, and it is fast becoming a necessity in every business and almost every home. But the standard machines at \$50 to \$100 are beyond the reach of a great many people. We have been on the lookout for

a good cheap typewriter to offer our readers. When the American typewriter was brought out a year or so ago at \$5.00 or \$6.00 we got one to investigate it. We decided that it was not durable enough to be serviceable very long. The manufacturers have recently brought out the No. 2 at \$8.00, in which they have overcome the defects of the former one. It is now quite strong and durable, and we consider it a great improvement over the World typewriter which we sold a few years ago. It has 75 characters, including capitals, small letters, figures, punctuation-marks, and the various commercial signs. A line 8 3/4 inches long can be written on paper 9 inches wide. It is very simple, and easy to operate. A child can learn to write on it, and in a little while will write faster than you can with a pen. If you do not write plainly you especially need a typewriter. There are some people who write to us to whom we would almost be willing to donate a typewriter if they would use it. If we can not give you all a typewriter we will give you GLEANINGS one year if you order a typewriter at the regular price, \$8.00. It weighs, boxed, 6 lbs. Every other subscription besides your own, which you send us, will count 35 cents toward the price of the machine provided at least half or more are new names. For instance, if you send 3 new subscribers and 2 renewals, with \$11.25, you get the typewriter and your own subscription advanced one year. This, you see, leaves \$5.25, the cost of the typewriter after taking out \$6.00 for the six subscriptions.

READY FOR THE RACE.

We are backing the "Only Elastic Fence" against "the Field." Watch the result!

The New Corneil Smoker.

BOTTOM

**Cheap,
Strong,
Serviceable,
Large Size.**

JUST THE THING for those who want a first-class smoker at a medium price. Size of cup, 3 1/4 inches; curved nozzle, hinged so as to swing back; legs of malleable iron, secured by bolts. The blast is the well-known Corneil principle. Weight of smoker, only 20 ounces. Here is what one of our customers says of it:

The Corneil smoker is a Dandy with a big D. I have been using it to-day on the crossiest colony of bees I ever saw. I think I could drive a bulldog with it. S. R. AUSTIN.
Amityville, N. Y., Oct. 15.

Price \$1.10, postpaid, or 85c if sent by express or freight with other goods.

CASH FOR BEESWAX

Will pay 27c per lb. cash, or 29c in trade, for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 32c for best selected wax. Old combs will not be accepted under any consideration.

Unless you put your name on the box, and notify us by mail of amount sent, we can not hold ourselves responsible for mistakes. It will not pay as a general thing to send wax by express.

THE A. I. ROOT CO., Medina, O.

W. O. Victor, of Wharton, Tex., took

45,000 Lbs. of Honey in 1894.

He offers Italian Queens—good, old-style honey-queens—untested, first order, to any address, at 50c each. Also bees in any quantity; 450 colonies to draw from. Root's goods constantly in stock. Prices to suit the times. Buy near home, and save freight.

HONEY COLUMN.

CITY MARKETS.

PHILADELPHIA.—*Honey.*—Honey has advanced in this market, with prospect of still higher advance. Comb honey sells quickly, and pure white-clover extracted sells on sight. We quote comb, dark, 10@11; choice, 14@15; fancy, 16. Extracted, 5@6; New York white-clover, 6½; western white-clover, 10. Beeswax, 27.

Nov. 23. WM. A. SELSER,
No. 10 Vine St., Philadelphia, Pa.

MILWAUKEE.—*Honey.*—The demand for comb honey is not large or urgent. The supply is very fair, and generally of good quality. The shipments come forward in general good order, showing an improvement in putting up and handling the sweet. Extracted honey, especially the white, is in small supply. We quote comb honey as follows: Best quality, 1-lb. sections, 15@16; second quality, 14@15; third quality, 12@13. Extracted, white, in barrels and kegs, 7½@8; dark or amber 5@7. Beeswax, 20@25.

Nov. 20. A. V. BISHOP & Co.,
Milwaukee, Wis.

KANSAS CITY.—*Honey.*—We quote white comb honey at 13½@14; amber, 12; dark, 10. Extracted, 4@7. Beeswax, 20@25. Demand good for honey.

Nov. 21. HAMBLEN & BEARSS,
Kansas City, Mo.

ALBANY.—*Honey.*—Buckwheat comb honey is coming forward very freely, and stock accumulating so that prices are less firm at 9@10. Clover continues scarce, and sells on arrival at 13@15 for good quality; No. 2, 11@12. Extracted very quiet; light, 6½@7; dark, 5½@6.

Nov. 23. CHAS. McCULLOCH & Co.,
Albany, N. Y.

DENVER.—*Honey.*—There is a little better demand for honey in our market, but quotations not much changed. We quote No. 1 comb in 1-lb. sections suitable for our cartons, 10@11½c. Extracted, No. 1 white, in 60-lb. cans, two in a case, 5@6c. Beeswax, 20@25c.

Nov. 22. R. K. & J. C. FRISBEE,
Denver, Col.

BOSTON.—*Honey.*—We quote our market on comb honey at 13@15, with a fair supply. Extracted, 5@6. No demand for buckwheat honey in this market, so can not advise shipments here.

Nov. 21. E. E. BLAKE & Co.,
Boston, Mass.

DETROIT.—*Honey.*—Best white honey is selling at 15; other grades, 12@13. Extracted, 6@7. Beeswax, 26 for prime yellow.

Nov. 21. M. H. HUNT,
Bell Branch, Mich.

KANSAS CITY.—*Honey.*—The demand for comb and extracted improved; prices about the same. We quote No. 1 white 1-lb. comb, 13@14; No. 2 white 1-lb. comb, 12@13; No. 1 amber 1-lb. comb, 12@13; No. 2 amber, 1-lb. comb, 10@11; dark, 8@10. Extracted white, 6@6½; extracted amber, 5@5½; extracted southern, dark, 4@4½. Beeswax, 22@25.

Nov. 21. C. C. CLEMONS & Co.,
Kansas City, Mo.

BUFFALO.—*Honey.*—Honey market is quiet; fancy in light supply, and wanted at 16@17; choice, 14@15; No. 2 white, 11@12. Buckwheat, 8@10. Beeswax, 25@30.

Nov. 20. BATTERSON & Co.,
Buffalo, N. Y.

CHICAGO.—*Honey.*—There is little change in the market as compared with recent quotations. The bulk of the offerings in comb is not strictly white; and such sells at 12@13; the Middle and Eastern States, white to fancy, 14@15; yellow comb, 9@10; dark comb, 8@9. Extracted, 4½@7, according to grade. Beeswax, 28@30.

Nov. 20. R. A. BURNETT & Co.,
163 So. Water St., Chicago, Ill.

CINCINNATI.—*Honey.*—There is a fair demand for honey, with a bountiful supply. Comb honey sells at 12@15, for the best white, in a jobbing way. Extracted honey brings 4@7 on arrival. There is a good demand for beeswax at 22@27 for good to choice yellow on arrival.

Nov. 8. CHAS. F. MUTH & SON,
Cincinnati, O.

CLEVELAND.—*Honey.*—Our market is not quite so good as when we last quoted you on honey. We quote No. 1 white comb, in 1-lb. sections, 14@15; No. 2 white, 12½@13; buckwheat, 10. Water-white extracted, 7; amber, 6. Beeswax, 25.

Nov. 20. WILLIAMS BROS.,
80 & 82 Broadway, Cleveland, O.

NEW YORK.—*Honey.*—We have a good demand for white comb honey, all styles, and it finds ready sale at 14@15 for fancy, and 12@13 for second grade. The demand for buckwheat comb is rather limited, and has fallen off considerably. The supply is large and the market shows a downward tendency. We quote pasteboard boxes and glassed, 10; unglassed, 9@9½. Extracted is not moving very fast, with plenty of supply, especially from California. We quote California, 5½@6; white-clover and basswood, 6; southern, 50@55 per gallon, according to quality. Beeswax is in good demand, and firm at 29@30. No demand for extracted buckwheat.

Nov. 22. HILDRETH BROS. & SEGELKEN,
28 & 30 West Broadway, New York.

WANTED.—To sell quantity lots of fancy comb honey. Also to sell water-white extracted honey in 60-lb. cans.

B. WALKER, Evart, Mich.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from cleome (tinted), 6c. Samples, 8c.

OLIVER FOSTER, Las Animas, Col.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty.

J. P. IYV,
Secretary Bee-keepers' Association,
Phoenix, Maricopa Co., Arizona.

FOR SALE.—1200 lbs. of honey, in 60-lb. square cans, 6½ cts. per lb., f.o.b. cars here. Sample by mail.

R. H. BAILEY,
195t Ausable Forks, Essex Co., N. Y.

Extracted honey in barrels at 6½ cts., or in 60-lb. pails at 7c.

CHAS. DADANT & SON,
Hamilton, Hancock Co., Ill.

CONVENTION NOTICE.

The Wisconsin State Bee-keepers' Society will meet Feb. 6, 7, 1896, in the Capitol building, Madison. Program later.
N. E. FRANCE, Sec., Platteville, Wis.

Wants and Exchange Department.

Notices will be inserted under this head at one-half our usual rate. Advertisements intended for this department must not exceed five lines, and you must say you want your advt in this department, or we will not be responsible for errors. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchange. Exchanges for cash or for price lists, or notices offering articles for sale, can not be inserted under this head. For such our regular rates of 20 c. a line will be charged and they will be put with the regular advertisement. We can not be responsible for dissatisfaction arising from these "swaps."

WANTED.—To exchange 26-in. planer, power scroll saw, all iron; tenoner, and mortiser, for portable sawmill, or other wood-working machinery. Will give a bargain for cash.
GEO. RALL, Frenchville, Trempe Co., Wis.

WANTED.—To exchange foundation-mills and honey-extractors for honey or wax.
I. J. STRINGHAM, 105 Park Place, New York.

WANTED.—To exchange 200 colonies of bees for anything useful on plantation.
ANTHONY OPP, Helena, Ark.

WANTED.—To exchange safety bicycles, Barnes No. 4½ lathe for metal work, Odell type-writer, for honey, beeswax, or gasoline or kerosene engine.
J. A. GREEN, Ottawa, Ill.

WANTED.—To exchange Japanese buckwheat for bee-keepers' supplies or fdn. mill.
PHILIP RATH, Oraville, Jackson Co., Ill.

WANTED.—100 to 200 colonies of bees and supplies, and will exchange my medical library of over 100 vols., value \$400 to \$500. Write what you have. I will send list of books. Also land in Florida would exchange.
DR. WM. BALL, 161 Main St., Norwich, Ct.

WANTED.—To exchange peach-trees, any or all the best varieties at 4c each, and Abundance, Burbank, and Satsuma plum-trees at 10c each, for bees. The trees to be shipped to you by freight or express in April, and the bees to be shipped to me by express in May or June. You to pay express charges on bees. Make proposition for one hive or more, and if we agree on a trade I will book your order for the trees and send them in April. In 1889 my apiary was in the city of Madison. There foul brood came. In 1890 I moved 60 colonies to this farm. In 1895, spring count, I had nary live bee. I want to make a fresh start.
JOHN CADWALLADER,
Cedar Grove Farm, North Madison, Indiana.

Niagara Grapevines, 2 by mail, 25 cents.

Japan Wineberry, 4 for 25 cents.

Ohio Raspberry sets and other new stock.

T. G. ASHMEAD,
Williamson, New York.

Potatoes.

Craig's Seedling, Everett's Early, and Freeman, at prices given by A. I. Root.

W. B. COLLINS, Blackwater, Cooper Co., Mo.

Something New!

A Comb-Honey Hive

containing 10 closed-end standing brood-frames, 15½x6½ net comb space, and 32 5-inch Prize sections 3½x5 in.; adapted to furnish standard Langstroth hives as bodies or supers with full space for top packing for safe wintering and promoting work in supers; forming solid double walls with intervening air-spaces tightly covered, and perfect bee-escapes, with all free of cost; manufactured by The A. I. Root Co., and now being exhibited by the inventor at the Atlanta, Ga., Exposition, in the Dade Co., Florida, division in the Agricultural building. One complete sample hive ready for bees, \$2.25; 10 complete in flat with nails, \$15.00.

MENTS.

FOR SALE.—Buzz-saw table, with Root mandrel, \$14; 12-in. rip and cross-cut saws and 8-in. ditto, \$5; form-table and 3 cutters, \$10; scroll-saw table and saws, \$8. These are all separate machines, and all have iron frames and wood tops.

M. S. JACKSON, 63 Sixth Ave., Pittsburgh, Pa.

World's Fair Medal

Awarded my *Foundation*. Send for *free samples*. Dealers, write for wholesale prices. Root's new *Polished Sections* and other goods at his prices. *Free* Illustrated Price List of every thing needed in the apiary.
Bell Branch, Mich. M. H. Hunt.

BEGINNERS.

Beginners should have a copy of the Amateur Bee-keeper, a 70-page book by Prof. J. W. Rouse. Price 25 cents; if sent by mail, 28c. The little book and the Progressive Bee-keeper (a live progressive 28-page monthly journal) one year, 65c. Address any first-class dealer, or

LEAHY MFG. CO., HIGGINSVILLE, MO.

POINTS OF SUPERIORITY.

1st Point. The *Bee-keepers' Review* gives reports of the work done at the Michigan State Experimental Apiary—gives them as soon as possible after the work is done, while they are fresh, of a newsy character, and can be of some benefit.

2d Point. It gives Hasty's monthly three-page review of the other bee-journals. Hasty is inimitable. He looks at things from a side-light, giving unique views that arouse one's thinking powers.

3d Point. F. L. Thompson is a practical bee-keeper and a thorough linguist. He reads ten of the leading foreign bee-journals, and each month furnishes the *Review* the gist of what he finds in them that is valuable.

Other Points of excellence are possessed by the *Review*, but these three are to be found in no other journal. The *Review* is \$1.00 a year. Last three issues of the old American Bee Journal for 1896. Ask for a sample, or send ten cents for three late but different issues.

W. Z. Hutchinson, Flint, Mich.

Don't Miss This Big Offer!

IT STILL HOLDS GOOD.

A Full Report of the Proceedings of the North American convention held at Toronto, Canada, will appear in the *weekly American Bee Journal* immediately after the meeting, Sept. 4, 5, and 6. The first installment will be in the number for Sept. 19. If not now a subscriber, you can have that Report free by sending \$1.00 now for the American Bee Journal for 1896, as we will "throw in" the balance of the year 1895, beginning with Sept. 19, to new subscribers. Think of it! over 15 months (or nearly 70 numbers) of the old American Bee Journal for only \$1.00! Sample copy of Bee Journal free.

And, besides all that, each new subscriber will receive a free copy of the 160 page book, "Bees and Honey." Better send on your dollar at once, and join the procession. Mention this paper, please.

GEO. W. YORK & CO., 56 Fifth Avenue, Chicago, Ill.

Proof Beyond Doubt.

A customer, looking over my 400 hives in home apiary, said, "Where are your bees? Mine were flying all around thick this morning." I said, "Just stop; look down at any hive." He was amazed. They were just pouring in thick with their heavy loads. This proves two things—they can't be excelled as workers, and quiet.

I opened several hives. He had no veil; was in the apiary 1/2 of an hour; was not bothered once. Try them. Untested guaranteed queens, 75c. Send for wholesale price list.

No. 23.

STRAY STRAWS

FROM DR. C. C. MILLER.

CELLARED my bees Nov. 13. Oh, but they're heavy!

LOTS OF FUN dreaming over what big things the bees will do next year.

SHALL I HAVE the pleasure of meeting you at the Chicago convention, Jan. 9, 10? [Yes.—Ed.]

WILL THE URBANE EDITOR of GLEANINGS kindly inform me whom I am likely to meet from Medina at the Chicago convention? [E. R. R. expects to be present.—Ed.]

NEVER FORGET that bees can stand more cold with good air than with bad. So can you or any other animal.

THE LINDEN, according to an article in Gravenhorst's *Bienenzeitung*, yields well only about four times in 26 years. Better get some American lindens.

FORMER ENTHUSIASM will come back through the meat diet, says Ernest, page 861. If some people only got their former enthusiasm they wouldn't be very enthusiastic.

FOUNDATION with wood base $\frac{1}{8}$ inch thick is favorably mentioned in Gravenhorst's *Bienenzeitung*. For extracting it has the advantage that no wire cloth is needed in the extractor.

PART OF MY BEES will be wintered in cellar this winter, the rest outdoors. Number in cellar, 157. Number outdoors, 1. [Fudge! only one outdoors? Why don't you try more?—Ed.]

THESE STRAWS are shipped from the Illinois State Bee-keepers' convention at Springfield, some being written in the \$4,500,000 capitol building. Small attendance, but lively interest.

WHY IS IT that bees get lazy in a little while when working on feeders, and keep up a life-long interest in flowers? Would they keep the same interest in the feeders if they traveled the same distance to them?

W. K. BALL, p. 864, wants his frames to

"stick" together so he can handle colonies by the hive. But if I can have my frames solid without any "stick" I don't want any "stick" in mine.

I'M NOT GOING to California. On p. 862 it is stated the average annual yield for 20 years is 7 pounds! Now, don't tell me that "70 pounds" was in all copies but one. I'm reading Mr. W. J. Finch's copy.

GRAVENHORST says that a box-hive man, or, rather, a straw-hive man: from 50 colonies took 5400 pounds of honey and 60 pounds of wax, and increased to 200. Then he naively remarks, "Pity that such cases are so rare."

THAT SERIES OF LESSONS now running in the *Southland Queen*, mentioned p. 865, is good, and is copied from the back numbers of the *American Bee Journal*. [This is a surprise. We turn to the Atchleys for a reply to this charge.—Ed.]

GRAVENHORST cherishes some hope that *apis dorsata* may yet prove an acquisition. He thinks there is not so much dissimilarity between it and the common bee but that a cross is possible. [Frank Benton says it is impossible.—Ed.]

ROUND STEAK, according to p. 861, comes, not from the shoulder, but from the "flank." What kind of "round" do you have in Medina, anyhow? Didn't you mean you get it from the "shank"? [That was a typographical error; it was corrected.—Ed.]

ALTHOUGH BEES are in cellar, I expect to keep doors and windows open day and night for some time—as long, anyhow, as keeping them open doesn't bring the temperature of the cellar below 40°. When it goes below that I'll shut up and keep at 45° or more.

HEATHER HONEY is so thick that as yet it has never been emptied by the extractor. One of the live questions at the present time in Germany is as to some machine or management by which it may be extracted, and the sturdy bee-keepers of that land are hopeful.

WHO FIRST INVENTED inoculation, or the plan of transferring a worker-larva to a queen-

cell? Pastor Weygandt, of Germany, practiced it in 1879. Was it known as long ago as that on this side the water? [We practiced it as early as 1880, I remember.—Ed.]

BADLY CHANGED. "Why, my dear Schultz, how are you? I haven't seen you for so long! but, dear me! how you have changed!"

"Excuse me; my name is not Schultz."

"My gracious! has your name changed too?"

DZIERZON, the German Langstroth, who invented movable combs in Germany, never allowed the advisability of end-bars and bottom-bars until the advent of the extractor. He used merely a top-bar; and when he wanted to remove a comb he cut it away from its side attachments with a knife.

THE BEE-KEEPER'S YEAR, says Lebrecht Wolff, in Gravenhorst's *Bienenzeitung*, does not begin in spring, nor Jan. 1, but Oct. 1. That's when I start a new record-book each year, and about the first entry is hauling home the bees from the out-apiary. Each volume of *Deutsche Illustrierte Bienenzeitung* begins, not Jan. 1, but Oct. 1.

TEMPERATURE alone will not decide when bees will fly. If badly in need of a flight they may fly at 40°, whereas they might stay quietly in their hives at 60° if there were no pasturage and they had not been long confined. They'll fly at a lower temperature in bright than in cloudy weather; and when honey is yielding than when nothing is to be had.

I WONDER WHY it is that in Germany heath-er honey brings lower price than clover, and in Scotland higher. [It's all in the taste, doctor. Some people think Limburg cheese very delicious, and others can't bear to have it in sight. But, say; in York State there are not a few who think buckwheat honey far superior to any white honey ever produced.—Ed.]

SWEET CLOVER. On page 846 the footnote says my failure with that piece of sweet clover was because "the seeding was too heavy." You're off, A. I. Not a plant was crowded. I've the rankest kind of growth this year, with heavier seeding; but the seed this year was *plowed under*. The failure was in soft ground, with shallow seeding, and the young plants shaded with a crop of oats—a bad combination.

AUSTRALIAN BEES have been successfully taken to England. An account in *British Bee Journal* says they are about one-third the size of the common house-fly, and they seem to be of value only as a curiosity. Can't sting, but bite, and die at a temperature below 50°. [They are probably much the same as our stingless bees of Mexico and the West Indies.—Ed.]

BOTTOM-BARS of wire have lately been mentioned as something new. I find them spoken of by Dzierzon, in 1875, as the invention of a

Danish bee-keeper. Dzierzon favored the use of wire for both bottom-bars and end-bars for extracting-combs. [I should rather suspect that the wire would prove to be no barrier—the bees would build the combs right past them as if they were not there at all.—Ed.]

AS LONG AS 20 years ago, unqueening colonies during the honey-harvest was practiced in Germany. I think it has gone out of use now. Dzierzon questioned the good wintering qualities of a colony that had been unqueened. [It is practiced to a considerable extent in York State, and with good results. One of our neighbors unqueens just before the harvest, and pronounces it a success; but it is a "lot of work," he says.—Ed.]

DO LAYING WORKERS put more than one egg in a worker-cell? They put several in a drone-cell, and a whole pile in a queen-cell; but I don't remember seeing more than one in a worker-cell. My assistant thinks, however, that I forget. When no drone or queen cells are present I've seen them make as regular work as a queen. [I think your assistant is right. I am quite sure I have seen a plurality of eggs from laying workers in a worker-cell.—Ed.]

IF ANY ONE knows any objection to having end-bars and bottom-bars the same width as top-bars, with $\frac{1}{4}$ -inch space between, will he please arise and state the objection? [It would be all right to have end-bars the same width as top-bars; but bottom-bars I should not want to exceed $\frac{3}{8}$ inch in any case. About $\frac{3}{4}$ inch wide by $\frac{1}{4}$ inch thick seems to give us the best results. If narrower, the bees build the combs, in some cases, clear past them, and fasten on to the next set of frames below. If wider than $\frac{3}{4}$ inch, there is almost sure to be a useless bee-space between the bottom edge of the comb and the bar. Unfortunately there is no width or thickness that obviates completely either of the above-mentioned difficulties.—Ed.]

THAT MOOTED HIVE QUESTION.

A CLEAR STATEMENT OF THE CONDITIONS UNDER WHICH THE EIGHT-FRAME LANGSTROTH MAY OR MAY NOT BE LARGE ENOUGH.

By R. C. Aiken.

Much has been written about "the best size of hive." Some of it has been guesswork, or at least without any clear conception on the part of the author. It is not enough to know that a few eight-frame hives, as compared with an equal number of ten-frame, or *vice versa*, gave more surplus than the other.

First, the hive must be large enough to hold sufficient stores and accommodate the colony. To illustrate: Here we have no honey to speak of from July or August till June. Sometimes September will give a living, and sometimes not. At times in April and May a little is gathered and at once used, but *never* added to store. The bees will fly more or less every month, and much in fall and spring, and breeding must start early to keep up the colony, or they perish in early spring from lack of numbers. In March, April, and May, and usually the first half of June, brooding goes on as rapidly as the strength of the colony will permit, provided the old stores are abundant, consuming much honey. I count on about 40 lbs. average as necessary, so that, as a rule, an eight-frame hive is not large enough unless *solid full* of honey—no empty combs on which to cluster. So we must use a ten-frame hive, or carry a stock of feed for use in the spring.

The flow here opens about June 15th to 25th. In five years with from 150 to 300 colonies I have found that I can not get an average of more than about six to seven combs of brood by June 15th; though with care to have all queens good we no doubt might average seven or better. Some colonies with feeble, poorly bred, crippled, or aged queens will get but three to five combs of brood, while the best queens will get seven to nine combs full. Shortness of stores, or scarcity of bees to care for brood, will also cause the colony to fall short in amount of brood. So, with good wintering and plenty of stores, we can count on having six to seven combs of brood June 15th; and as a few queens will do 'extra, filling eight to ten combs, the eight-frame would not be large enough unless we took from the strong and gave to the weaker.

I have no doubt that where 20 to 30 lbs. of old stores is sufficient for winter and spring, and where the brood is equalized by the apiarist, that the eight-frame hive will do very well. Nor do I doubt that the smaller hive will increase the disposition to swarm in general. If there has been a complete dearth of honey from the fields, and if the stores are well consumed and the colonies strong, the large hive will be first to swarm because it has the most old honey; but if all have *plenty of stores*, the small hive will cast swarms first.

I contend that the large hive, with its abundance of honey, will bring the largest colony. One condition, however, will make the small hive equal to the large in the quantity of bees reared; and that is, a constant supply of nectar coming in, sufficient to keep up the needs of the colony. Talk as we will about size of hives, and feeding, one thing is certain—if we get the best results in breeding we must not stint the colony in stores; and the locality that will not furnish it from the fields must fall back on old stores or the sugar-barrel.

Now, according to the foregoing it appears that in *poor* to *fair* seasons for brood-rearing, the eight-frame hive will accommodate all brood and necessary stores when a living can be had from the fields from four to six months of the year. In fair to good seasons for brooding, the apiarist may need to *equalize* brood to give the best queens room, and some colonies may breed so much that a shortage of nectar may put the colony in a starving condition, which, if it occurs *any time* within six or eight weeks of the opening of the flow, ruins that colony for that flow. The hive that is big enough one season may not be the next.

The rapidity and duration of the flow also has a bearing on the question. Whether the hive be large or small, if it be full of bees we expect good work. Should the flow be slow and "long drawn out," i. e., thirty to sixty days, a contracted hive will *force* the bees to the sections sooner (this does not apply to those run for extracted unless they have their combs to build), and will result in more section honey, while the brood-chamber will be filled with brood to the exclusion of winter stores; and, in case of extracting with full sets of combs, will leave the colony with nothing but brood and bees. If the flow comes with a rush, there will be but little difference in the quickness with which they enter the sections, and little difference in the total yield. The difference will be mainly in the amount of the extra combs in the brood-chambers, *provided, however, these combs were empty when the flow came; and if they were empty, there must have been more honey converted into bees in the large hive*, consequently more honey gathered.

Here, the difficulty is not in the hive being large enough in which to rear a strong colony of bees, for I can not get an average of over six to seven combs of brood by the harvest time, but the constant danger of short rations at the most critical time. The small hive will hold the brood, and the bees can pile on the outside. If eight frames of stores and the incoming nectar will *surely* keep the colony from *even feeling the need of economizing*, it is large enough to give good results; but if it will not do this it is too small.

IMPORTANCE OF STRONG COLONIES UNDER ALL CIRCUMSTANCES.

Some write as though a colony could get too strong. How it is possible to get one too strong without doubling, I can not understand. I know that, in poor seasons, only strong colonies will do well, even in getting winter stores. In a *fair* season the strong colony will outstrip the average colony; and in a *good* season the strong colony must certainly do the best, for surely two pounds of bees can and will gather more honey than one pound. I have never been able to believe that apiarists are able to get colonies so strong that they refuse to work.

I admit there is a little more energy in proportion to numbers when the energy is necessary to get the brood-nest into shape; but this does not apply to the colony already in prime strength. I can always get more and better work in the sections when I have colonies so strong that they *must* occupy the super. If the flow comes very freely while it does last, we do not notice it so much; but when the gain is one to two, and even three pounds a part of the time, per day, it is almost impossible to get *even reasonable* work in sections with a colony that has not swarmed; while the one that swarms will do almost nothing in sections; but two colonies put together in one hive the bees and enough brood to *fill* the hive will do fair to good work. This year our flow began June 20. My scale-hive colony was stronger than the average, and was not allowed to swarm. It is a ten-frame hive. The gain from June 20 to July 15 (the extent of the flow) was an average of $2\frac{1}{2}$ lbs. per day. The best day's work was 6 lbs. This colony gave about 25 sections. Many other average colonies in nine-frame hives, and a few in eight-frame, gave from nothing to about one super, the majority not giving ten good sections. In one case I put the force of two colonies in one nine-frame hive, and got two 28-section supers. Another colony on nine frames had the forces from two other colonies added, and gave three 28-section supers. All the evidence goes to show that, if I had *doubled the forces* of all, preserving the old stock in the original hives, I should have had as many colonies in the end, and about doubled my surplus.

I could also have doubled the surplus by contraction, but at the expense of stores which I *must have*. In twenty years of practice, in which I have always kept at least a part of my colonies from swarming, that I might have the advantage of the strength, I am as firm as ever in the belief that we can not get our colonies too strong. A very strong colony *may* do as well, and *sometimes* a little better, when in two average hives, if the flow be very good, coming in very rapidly; but in a slow and moderate flow, the stronger the colony the better the results.

The apiarist who has intelligence enough (knowledge of the business) to know how much brood he can get by the opening of the harvest with *plenty* of feed within and without, will know the size of hive he needs. The small hive will the more often fail *because of shortness of stores* than will the large one because of *too much room* for storage in the brood-combs.

Loveland, Col., Nov. 11.

EIGHT-FRAME HIVE FOR WISCONSIN.

WHY IT IS LARGE ENOUGH, AND WHY BETTER THAN THE TEN-FRAME SIZE.

By F. L. Murray.

Mr. Editor:—I see you ask in your Nov. 1st issue for bee-keepers to give you the size of hive they are using in their locality, in order to make a map showing where different-sized hives are used. I have been keeping track of the hive discussion with great interest, and I think the map scheme would be a good thing, as it would give a better idea than any thing else yet spoken of in regard to large or small hives, as I believe the location has more to do with the hive question than any thing else.

In my location I do not want any other hive than the eight-frame Dovetailed. I have been using them for a number of years, and, until I see something more definite than has yet been published in favor of the ten-frame (or larger) hive, I will continue to use the eight frame. By preferring the smaller hive I do not claim that eight frames give sufficient room for all queens, for I have had queens that would keep twelve and fourteen frames full of brood, so you see a ten-frame was not large enough.

Now, in working for comb honey (and I work almost exclusively for that), I put a second hive-body, full of drawn combs, about May 1st, on all strong colonies. That makes a sixteen-frame hive, and (I have had no trouble about queens refusing to go up into the upper story when crowded for room below) that gives all colonies a chance to build up strong for the honey-harvest which begins here about June 10, from white clover. At the beginning of the honey-harvest I take off all those second stories. I fill up the under story, or hive proper, with brood, of course being sure the queen is below; and if there is any more brood than will fill up the hive I strengthen up weak colonies with it, or make increase. In this way I confine my working force on eight frames; and by putting on the surplus-arrangements as soon as the second story is taken off I always get my share of the honey if there is any to get. I do not want any larger hive than the eight-frame, for comb honey, for eight frames give all the brood room I want after putting on the surplus-arrangement; and if I used a larger hive I should have to use dummies; and I do not like to use them, for various reasons. I also find, when wintered in the cellar, the above hive gives all the room necessary for winter stores; and an eight-frame hive full of bees makes a *pretty strong colony*, and the eight-frame hive is much handier to lift in and out of a cellar. When bees are kept where the person keeping them has too much other work to do to attend to them properly, I think a large hive would be preferable; but for a practical bee-keeper who

If you would like to have any of your friends see a specimen copy of *Gleanings*, make known the request on a postal, with the address or addresses, and we will, with pleasure, send them.

understands the proper manipulation of bees, the eight-frame hive is about right here.

Calamine, Wis.

[You and friend Hatch do not agree, although you are both of the same State. You will remember that, in the first place, I too, in answer to him, took the same or nearly the same position in favor of the smaller hive. While locality has much to do with this question, it is evident that the individual tastes and preferences of men, even in the same locality, have much to do with it also.—Ed.]

AN OPEN LETTER TO DR. MILLER.

THE QUEEN THAT SULKED; HOW TO GET
QUEENS TO OCCUPY ONE OR MORE
STORIES.

By Delos Wood.

Dr. C. C. Miller:—I have just read your article on page 739, Oct. 1st GLEANINGS. In your closing paragraph you intimate, as usual, that you "don't know," and ask for more light. Perhaps I can lend you a candle for a few minutes. You complain that, when you took the queen out of the story she was laying in, and confined her to another with empty combs, she "sulked and would not lay." Now stop right here and think what you did, and then, instead of blaming the queen for "sulking," you will probably ask Miss Wilson to make you a paper cap such as I had to wear sometimes in my schooldays.

When you changed your queens you took them away from the nurse bees, and left them with only the old field-workers, and the queens were *compelled to sulk*. Next year, when you want to put the queen in confinement, take two combs of unsealed larvæ with the adhering bees, and put them into the story you put the queen in, and give them the other six combs empty; and if the queen *sulks*, send the paper cap to me and I will wear it.

At one time I thought I knew all about bees; but I have had 30 years' experience since then, and find, like yourself, I am compelled many times to say, "I don't know."

I work entirely for extracted honey, and tier up as many stories as may be required, always using the same-sized story and frames. I use loose hanging frames. My hives are 16¼ in. long, 13½ wide, 10½ deep, inside measurement. I use 9 frames with loose bottoms and tops. I always work them two stories high, and tier up more if unable, from any cause, to extract as soon as needed. My queens *prefer* the top story, and I have never had a queen that would fill more than two stories. Empty combs below will not prevent swarming in my "locality."

This season I have had two colonies with two laying queens in each. One of them I found in April, and they were still working side by side in September, and may be there now for all I know to the contrary.

NOT SIGHT BUT PROOF OF A QUEEN'S PRESENCE NECESSARY.

Miss Wilson objects to tiering up because it is harder to find the queen. What does she want to see the queen for? *Proof* of her presence is all I want. Queen-breeders, of course, will keep the queens for sale in a hive easy of access, but not so with the honey-producers. Of course, you will not expect her to lay in old combs that have been out of the hive all winter.

Santa Barbara, Cal., Oct. 12.

[Dr. Miller replies:]

I don't know whether I'm willing to put on that cap or not. I have some doubts about it. Of course, any one knows the queen will lay wherever two combs of unsealed larvæ with adhering bees are put. That's about equivalent to saying she'll lay in the brood-nest, for it's simply transferring a part of the brood-nest. But why won't she do it without the brood and adhering bees?

You say, when I changed my queens I "took them away from the nurse bees, and left them with only the old field-workers." Didn't either. I put the queen alone in the empty chamber above, without any bees, an excluder between. There was nothing to hinder the nurse bees going up any more than the fielders. The bees did go up, plenty of them, and for days that queen stayed up there sulking with the chamber full of bees. Now do you know that those bees that went up were all field bees and not nurse bees? What call have worker bees to go up into an empty story any more than nurse bees? Isn't it rather the other way? When the bees go up of their own accord to enter the surplus-chamber, is it the field bees or the nurse bees that go up first?

It looks a little as if the bees had said, "There's no nectar coming in, and we'd best do nothing in the way of enlarging the brood-nest." But when the brood had hatched out below, why did they remain without any brood rather than start in a new place? Would they not have acted differently if honey had been yielding?

If Miss Wilson has any good reason for wanting to see queens, she can give it herself; but you know that women are generally supposed to have a great deal of curiosity.

C. C. MILLER.

[There is one point in the last paragraph of friend Wood's letter that I am interested in. It is not new, but it is one that needs far more attention than it usually receives; viz., accepting the proof, as friend W. puts it, of a queen's presence, rather than going to, oftentimes, a large amount of trouble to get a view of her. I never think of looking for a queen (and I don't suppose Miss Wilson or the doctor does either) when I have seen one good comb with brood and eggs, properly distributed. Beginners, and perhaps some of the veterans in some cases, knock quite a little slice off their profits from honey by hunting for queens when it is not necessary. Of course, there are times when it is

necessary; such as, for instance, wing-clipping, superseding for the purpose of introducing, or raising another queen.—[Ed.]

NUMBERING HIVES.

INVISIBLE NUMBERS: THE GROUP PLAN OF S. E. MILLER.

By S. E. Miller.

Friend Root:—Seeing so much said, lately, through the bee-journals about numbers for hives, it has caused me to offer my method, which is without numbers of any kind, except those kept in my head, and I do not think these are made of tin, manilla paper, or any other similar material. I did not know, however, that others were using a similar system to my own until I saw in the *American Bee Journal* for Oct. 31 the plan given by R. V. Sauer; and this evening, in looking over the editorials in *GLEANINGS* for Nov. 1, I notice what you say in reference to what E. E. Hasty had to say in the *Review* regarding hive numbers and toads' tails.

S. E. MILLER'S PLAN OF AN OUT-APIARY.

My method is not exactly like Mr. Sauer's, Mr. Hasty's, or Mr. Boardman's, and yet similar to all. Mr. Hasty numbers his groups, while I think letters for the groups are preferable. But without further preamble I will give my method.

If the reader will refer to page 21 of the A B C of Bee Culture he will see the S. E. Miller plan of an apiary. This plan was first given in *GLEANINGS* about five years ago, but I can not tell the exact year and number without overhauling a pile of back numbers.

Probably the editor could help out here at giving the number, or he might have a cut of the plan lying around the shop somewhere, with which to illustrate it if he considers it worth the trouble.

The hives are arranged in groups of 5, so that, for an apiary of 80 colonies, it will take 16 groups. We will say we stand on the south side of the apiary, and, facing it, we will call the southwest group A; and, going east, B, C, D, in succession. The first group on the west end of the second row is E, and so on throughout. Each group having 5 hives, the numbers run from 1 to 5. Thus, facing a group and looking north, the southeast hive of the group is 1, and the northeast group is 5. So the hive that occupies the third position in the third group is C3. It does not matter whether I am at home or abroad, that particular position of the apiary is where C3 belongs, and it doesn't have to have a big tin tag nailed fast to it either. And now see here, Mr. E. R., you may be older than I am, and know much more; but I'll bet you are not any bigger; and if you think you can put us fellows, who prefer to

carry our hive-numbers in our heads, aside by a wave of the hand, or even by a six-inch editorial, you are mistaken.

And now let us see what we have to say in favor of numbers in the head as against numbers nailed to the hives.

First, it is obvious that the stand and not the hive should bear the number. If No. 10 is here to-day, you do not want to look away over yonder for it to-morrow, which would be the case if No. 10 should swarm and you wished to remove the parent colony to a new stand, and hive the swarm where the parent colony stood, unless you should pull off that number (that you ought to have in your head) from the parent colony and nail it fast to the hive, and then go and get a new number for the parent colony. Certainly, for those who winter in cellars a number is

necessary if one wishes to have each colony occupy the same stand in the spring that it was taken from in the fall; but these numbers need be only temporary, and a piece of blue or red crayon would do very well to mark the hives with while they were in the cellar.

Second. These numbers are always where they belong; and if the apiary is laid out in any thing like order they are as stationary as the lot on which your house stands; while numbers, if hung on a nail driven into the hive, are liable to blow off and get lost in the grass;

or, if nailed or tacked on they must be pried off and nailed to another hive whenever it is necessary to change a hive from one stand to another; and we all know that such changes are frequently necessary, especially in swarming-time.

In that editorial you say, "But suppose he hired help, and he should direct his man, not very familiar with the arrangement, to 16-9." I will tell you how I would direct that man. If I wished him to get the queen from G5, and he had never seen the apiary, I would say, "Go to the apiary. Go in at the south door of the honey-house. When you get in, turn to the right, and look at the plan of the apiary tacked to the wall just beside the door. After looking at it a minute or two, if you can not locate G5 come and tell me and then go home.

What I claim for my method is that one letter and one figure indicate the number, there being no number higher than 5. Some may argue that having the same numbers so often is likely to cause confusion in keeping the records; but I find in actual practice it is not the case. One is not likely to mistake one letter for another; and bearing in mind that the southeast hive in each group is 1, and that the numbers go round like the hands of a watch, there is little likelihood of getting the numbers wrong. Let me give a sample record. I have not my book at hand, so will give you a sample from the same place that I carry my hive numbers.

H3, Mar. 15, strong, plenty of stores; May 28, swarmed; hived swarm here, and removed parent colony to L4; June 20, gave super.

By referring to the record of L4 we shall see where they came from, and will know that the queen is a daughter of the queen in H3; if all went well, we shall know she was reared by natural swarming; her age, etc.

Now let that other Miller tell us why he would have his big tin numbers nailed to the hives instead of carrying them in his head.

Bluffton, Mo., Nov. 4.

[We have reproduced the diagram in the A B C, for the convenience of our readers. Well, while I have no doubt that you can get along without the visible numbers, can't see what harm their presence on the hive or in the group can do, and it might be a great convenience. Why, it would save having a diagram or plot "tacked to the wall just beside the door." Then some chaps whom you might send there might commence numbering from the wrong side or end.

As to our own practice, we have never numbered our hives; but we had seriously thought of doing so, because it was inexpensive, and might be an advantage.

Perhaps it would be well to state that we have been using the Miller plan of grouping hives, in one of our yards, for several seasons. We like the arrangement very much. It economizes space, gives an alley for bees and one for the bee-keeper; and then, too, one hive makes a handy seat for working over its neighbor.—ED.]

RAMBLE NO. 144.

A SKETCH OF HARRY E. WILDER.

By *Rambler*.

During the past few months I have made quite free use of the name of my traveling-companion; and to atone, in a measure, for the jokes I have thrown at him I will in this ramble present him to your readers in the character of a progressive bee-keeper.

Harry E. Wilder was born about 28 years ago in Peterboro, N. H. His father has for many years been a manufacturer of thermometers; and any reader of this who owns a Wilder thermometer has the best and most reliable mercury-tube in existence—at least, Harry so insists. Thousands of thermometers are turned out of the factory, and for all conceivable purposes.

HARRY E. WILDER.

Harry lived under the paternal roof, with several other chips from the old block, male and female, until he arrived at the age to which all young men look forward with longing. At his majority he started out to experience the ups and downs of life among strangers and under new surroundings.

From early life our friend was an ardent lover of the chase, and his gun and hounds were familiar features on the streets of Peterboro. It may be readily surmised that the "hunting" around Peterboro was not of a wide and varied character; and a lover of such sport, when the opportunity came, would naturally seek the wild portions of our far western country, where both large and small game is plentiful.

In the interests of an eastern publishing company our friend found his way to the Pacific coast; and in Washington, Oregon, and California, when business cares were not pressing, the highest mountains and deepest canyons have been explored for game and natural wonders.

In 1890 he arrived in Southern California. Up to this time he had never been interested in the honey-bee. There were but few bees kept in his native town; and the few there were never attracted much attention from methods of management or from the yields of honey. He possessed the idea, common to a great many, that, the further he kept from a bee-hive, the better health he would enjoy. But in this land of sunshine he met with people who were making some money out of bee-management; and soon after arrival he was taken with a violent fit of bee-fever which did not cease its raging until he had paid \$400 for 100 colonies of bees. The person from whom he purchased the bees gave him his first instructions in management; and for a novice, and the first year, the results only opened his eyes to the fact that there are more things in bee-keeping than the average novice had ever dreamed or imagined, and his appetite for investigation was sharpened by his first year's experience. He became a subscriber to GLEANINGS, a student of Prof. Cook's Guide; and every bee-keeper, far and near, contributed to his knowledge, for he was not afraid to ask questions.

The apiary was located upon the north side of the San Bernardino Valley, near the mouth of Devil Canyon. Considering that Devil Canyon was not a good neighbor, the second year he changed his location to a series of rocky hills toward the south side of the valley, near Riverside. Here he found a canyon that fitted his name, "Wilder;" and as it was government land, and of no earthly use except for bee-pasturage, he took up a government claim and established himself near a beautiful spring of water, and here we find him to-day.

Mr. Wilder would disclaim any idea of being a scientific bee-keeper; but I think the name fits any person who manages his bees so as to secure the very best results from them and his field. As a step in line with scientific bee-keeping Mr. W. believes in managing only the number of colonies that he can thoroughly attend to; so he has never had less than the original number (100), nor more than the present number, 150.

In the early spring Mr. Wilder is in his bachelor cabin, believing in the old adage that "whatever is worth doing at all is worth doing well." The condition of every colony is investigated and noted.

The first essential to a good honey-yield is a vigorous queen. Nuclei are started as early as the season will permit, which here is in the latter part of February or early March. The queen-rearing is performed according to the Doolittle plan, and the nuclei are kept going through the whole season. Any queen that becomes superannuated, or fails to deposit eggs with due rapidity, is killed, and a young vigorous queen introduced in her place.

The next point is to give the queen ample room to deposit eggs. This line of work finds the hives just boiling over with workers as soon as the honey-flow opens. The results from close attention to these few little details are usually good; and during the past season the apiary of 120 has been increased to 150, and 17 tons of honey secured, or 283 lbs. from each of the original 120 colonies. It is also safe to say that two or three tons more could be taken from the apiary, without detriment; but Mr. W. is very provident in giving abundant stores for wintering. The honey does not spoil in keeping over till another season; and the plan two years ago enabled the apiary to pull safely through the poor season of 1894 with but a trifling loss.

The hive used in this apiary contains a frame the measurement of which, speaking in round terms, is 10 inches deep and 14 in length. He has a few which contain 13 frames, and I think he is partial to the jumbo idea; at least, when he saw a few Heddon hives in my embryo apiary he wanted to know what I expected to do with "those pumpkin-seed hives."

Mr. Wilder is anxious to find out whether bee-keeping as a pursuit can be made a paying business when worked independently of other pursuits. The success of the present season gives some encouragement that it may be made a paying business so far as production is concerned; but in the matter of prices the California bee-keeper labors under an immense disadvantage; and I think that in this alone is found the great Nemesis against the highest success on this coast.

If we step inside of Mr. Wilder's cabin we find many specimens of his handicraft as a taxidermist. A wildcat stares at us from a corner of the room, while several wildcat skins and a coyote skin are doing service as rugs, etc. Owls, hawks, and an endless procession of rare specimens of the feathered world stare at us with glass eyes.

Mr. W. is something of a literary man, having written up our last season's journey in fine style for the local paper at his old home in Peterboro, N. H. He might give some interesting articles to the bee-journals, but seems to be somewhat modest in relation thereto.

Upon the whole, the success of Mr. Wilder shows what a young energetic man can do here in the bee-business, with a very little capital; and if there are any young men in the East who contemplate migrating to this sunset land, please consider the above facts, and do not forget the capital and the energy.

[I sincerely wish our friend would write occasionally for these pages. If the article he did send us some time ago is a fair sample of what he can do he is one of the brightest, spiciest writers that ever wrote for GLEANINGS. There, there! I don't mean this for "taffy" or a "bait" to draw him on; but a bee-keeper of

WILDER CANYON AND APTAHY. RAMBLER 144

his all-around talent, and the success which has been his, should let his light shine.

By the by, he has an interesting history; but there is only one thing lacking to make it round and complete—a—dare I say it?—some fair Eugenia who would make that wild canyon fairly blossom, and Wilder the happiest man on earth.—Ed.]

ENTRANCE FEEDERS.

THE BOARDMAN AN OLD IDEA; SHADE, AND ITS EFFECT ON THE TEMPER OF BEES; A QUEENLESS COLONY RECOGNIZED BY THEIR NOT CARRYING IN POLLEN, ETC.

By E. H. Schaeffle.

About twelve years ago I purchased of Mr. C. F. Muth a feeder made from the Mason jar, screw top. The top was cut out, a piece of finely perforated metal soldered on, and a rim an inch deep soldered on. This made a good feeder if the jar, when first inverted, was placed over some receptacle until sufficient vacuum was created to cause the honey to feed slowly. Wishing to feed at the entrance, I made a thin box with tin bottom, and projecting strips at the open end. The top was of wood, with circular holes a little smaller than the rim on the feeder. The half-gallon Mason jar was inverted, placed over the hole on the top of the feeder, and it took care of itself. This did very well for hives having a wide entrance. I believe this is about the same as the Boardman feeder.

By the way, Mr. Boardman claims that, with a square hive, the queens won't go up into the sections. I have 140 square Gallup hives; and unless prevented with queen-excluding zincs the queen goes to the top super almost every season. I extracted several hundred sections of that kind last season, and had a few left to show Rambler when he was here. This season I find the queen would have done the same as in the few hives without zinc. The sections are full of brood. The queen does not wait for the cells to be drawn out, but lays her eggs as soon as the cup is deep enough to hold them. Where the flow of honey is limited or short, there may be no trouble of this kind. Shutting a queen up in sections, during a poor season, and not finding any eggs in the sections, proves nothing. The chances are that she would not have laid in the brood-nest, as she and the bees don't start a family when there is a doubt about its support.

Mr. Muth-Rasmussen once stated that bees are better-natured in the shade, and his statement was poo-hooed. A neighbor had an apiary that made the life of himself and family a burden. They were the most vicious bees I ever saw, and were a constant annoyance to me as well, so I bought them. He had them out in the sun, without any shade. I placed them in the shade of a row of apple-trees, within a few feet of a public sidewalk, and in the shade they

are as gentle as any bees I have. Eastern apiarists should remember that conditions with us are entirely different from the East. If they could stand their bees and themselves out in the heat when the thermometer registers 112° in the shade they'd soon find both the bees and themselves changing their angelic dispositions.

I stated last season, that, in the early spring, a queenless colony could be told by their not carrying in pollen. I made that statement after an examination that, in every instance, proved I was correct. Some of the bees were late fall swarms. In their combs there was *no pollen*; others were old colonies whose combs were full of old pollen from want of young bees to feed it to. When Rambler was here I showed him a drawing of a twelve-frame hive that I had made several years ago, and talked over its construction with him. He said:

"Look out for Heddon!"

"Why?"

"Well, he claims a shallow divisible brood-chamber as his patent."

"Don't all bee-keepers allow the queen access to all the extracting-supers in her spring laying, and afterward confine her to the lower brood-chamber?"

"Yes."

"Well, if you'll go over here to Columbia you'll find a bee-keeper who works all of his bees in 1-lb. supers, filling them all full of 1-lb. sections. It suits him but it wouldn't me;" and the last I saw of Rambler and Wilder they were headed for Columbia.

Now, there may be something in Mr. Heddon's hive that is patentable; but no one, certainly, can claim a patent on a hive because it is four inches or four feet deep. I have bought up all the bees in this section, and have a grand conglomeration of every shape, size, and style, from four inches to four feet in depth—box with cross-sticks, to the Dovetailed. All I want is an old-fashioned straw skep to gild and place on top of my bee-house.

This is my first season with the Cogshall bee-brush. When once you get the hang of it you can brush down the bees as slick as a Pullman porter does your clothes. It's "way up."

The Manum swarmer is good; but in its absence I found that a light box, 8 in. deep, 18 in. long, 12 wide, with screw-eye and hook in one end, did finely. Wet the box thoroughly; brush in the bees, hang it on a limb or the ladder, and brush the remaining bees off their alighting-place. In a few minutes they will all gather into the box, and can be carried anywhere.

I trust the bee-men will keep up the agitation for a 50-lb. honey-can. In its absence I use a light block and tackle, which lifts the extractor up on to a table. When I wish to strain out the honey I pick up a can of it and drop it into a case as cleverly as Sandow could do it, and all without any strain on my part.

Bees with me are doing nicely. I shipped half a ton of this season's extracting, in the middle of April.

I notice that Mr. Crane states very plainly what he has been allowed a patent on. Will you give us a similar statement in regard to the Porter escape? I think a better one can and will be invented; but no one wants in any way to infringe on a just patent.

Sometimes since I suggested in GLEANINGS a system of transferring by drumming the bees up into a hive having at least one frame of brood, then placing a queen-excluding zinc over it, and the old hive over the zinc, and, when the bees had all hatched out, placing a bee-escape board under the old hive, and thus get the combs free of bees and brood. The idea was new to me; but I see since that it is the system used in France, which proves its value and previous use.

Murphy's, Cal.

[The principle of the Boardman feeder is old, and, indeed, I do not know that our friend has made any claims as to its being new. Yes, atmospheric entrance feeders are quite old. In looking over our back volumes I find quite a number. In GLEANINGS for 1881 and '82 several were illustrated; for 1881, see page 477; for 1882, see pages 174 and 221; and, again, one was shown and illustrated on page 561 for 1891. But the one on page 174 for April, 1882, by A. C. Kendel, resembles the Boardman more closely than any other, and some might pronounce it almost identically the same thing. But Boardman's is the cheapest and the best of all, and of late I have seen quite a number of excellent testimonials from those who have tried it since we illustrated and described it on page 346, current volume. The lower part (see adjoining cut) is made of wood, and gives plenty of room for the bees to cluster around the lid, secure from outside intruders.

The following are the claims upon which a patent was granted to the Porters.—Ed.]

1. A bee-escape comprising in combination a body having an opening in its top to register, with an opening in the escape-board whereby it is adapted to communicate with the super and open it at its end to adapt it to communicate with the brood-chamber, said body providing a passageway between the super and brood-chamber, and a guard of spring metal arranged in said passageway with the movable portion thereof normally out of contact with the top and bottom of the passageway, and adapted to yield laterally to the pressure exerted thereon by the escaping bees, and by its resiliency to close the passage against their return, substantially as described.
2. A bee-escape comprising in combination a body having a passage whose ends open outside the body, and a spring guard-piece arranged in said passage, and having one end thereof secured to a flexible, inelastic part of the structure, and its opposite end free, whereby by bending said flexible part the free end will be adjusted to vary the size of the passage, substantially as described.
3. A bee-escape comprising in combination a body having an opening in its top to register, with an opening in the escape-board, whereby it is adapted to communicate with the super, and open at its end to adapt it to communicate with the brood-chamber, said body providing a passageway between the super and brood-chamber, and said passage having placed therein a laterally yielding resilient guard-piece, the movable portion whereof is normally out of contact with all fixed parts of the structure, whereby clogging of the guard-piece with deposits made by the bees is avoided, substantially as described.
4. A bee-escape having a passageway adapted to communicate at one end with the super, and at the other with the brood-chamber, a spring guard-piece arranged in said passageway, and a chamber underneath the entrance to said passageway, and at a lower level than the floor of the passageway, whereby clogging of the passageway with dead bees is avoided, substantially as described.
5. A bee-escape comprising in combination a passageway adapted to communicate at one end with the super, and at the

other end with the brood-chamber, and a guard of spring metal arranged in said passageway, and having one end thereof secured to a flexible inelastic part of the structure, and its opposite end free, whereby, by bending said flexible part, the free end may be adjusted to vary the size of the passage, substantially as described.

6. A bee-escape comprising in combination a supporting-plate having an aperture therein, a shallow open-ended metallic body secured to the under side of said supporting-plate, and forming a passageway, spring guard-pieces arranged therein, and an outer box-like body having one open end, and secured to the supporting-plate around the body containing the guard-pieces, and closing one end of said passageway, substantially as described.

JAKE SMITH ON ADULTERATION.

The other day me and Zed went into the store. They was a nice-dressed man a talkin to Nat Boucher, the man that keeps the store. The stranger had a sample of hunny he was a sellin, and Nat had just bin a tastin the hunny, and said it was 1st class, and he thot he mite try a few pounds of it. Besides the bottle he had the sample in, he had it in cans to sell. I mean the man had, not Nat. It had nice labliss onto it, with pictures, and marked Pure Hunny. The stranger held it up to show how nice it looked, and was a tellin Nat how he could easy sell 1000 pounds of it, and just then Jim Short came in.

Jim listened to him reelin off his story for awhile, and then says he to the stranger, says he, "When you see hunny nowadays, you don't know whether it's hunny or not. How's a buddy to know whether that of yourn is the simon-pure juice of the posies or some of the city-made stuff?"

The stranger looked at him, and says he—he was a real pleasant-spoken man, and says he to Jim, "My friend, I'm afraid you've been reading some of the newspaper yarns. It shows you're a man of intelligence, and read the papers; but you mustn't believe all you read. That stuff about adulteration of hunny is all pure rot. There's nothing to it. Not a thing. Why, just think of it. I appeal to you as a man of judgment and discrimination, which I can see by you're appearance you're that sort of a man—I'm out in the world a good eel, and a man in my position learns to read character pretty well—I appeal to you if it's reasonable that men would buy glucose or any thing else to mix with hunny, when the bees furnish the pure article for nothing. Bees work for nothing, and board themselves; so a man would be a fool to try to make munny by mixin something with his hunny that would cost more than the hunny itself. No, sir; no one can afford to adulterate hunny. They wouldn't be any munny into it."

"Well, now," says Jim, "that does look kind o' reasonable; but supposin a man hadn't any bees, and bot glucose at 3 cents a pound, and then sold it at 10; it seems to me they would be some munny in it, even if he did mix some hunny with it. Fact is, you ain't sure of nothin bein pure nowadays. If I had my way I'd string up a few of the scoundrels. Hunt

out the men that mix glucose and hunny, and put 'em to the full extent of the law."

"That would only make matters worse," says the stranger. "Why, if it hadn't been for the everlasting clack of bee-keepers themselves they wouldn't be half as much said about adulteration. What good does it do to make such a fuss about it?—only makes folks suspicious. Come right down to it, what harm is there in glucose? It's a good wholesome article. And you can't tell it from pure hunny, so where's the difference? In fact, these men you come down so hard on are doing a good thing for bee-keepers. When it's a short crop they help to fill in and keep up the supply soze people don't get out of the way of wantin it."

"Stranger," says Jim, "may be you're right; but that's a kind of new way of lookin at it. May be it would be better to keep things hushed up. If a lot of counterfitters gits up a lot of bogus dollars that common folks can't tell from the genuine, you think it ain't best to say any thing about it; but increase the circlelation as much as possible. It would help to keep up the supply when munny is skerce. If you can't tell the bad munny from the good, where's the difference? Now, look here, stranger; I hain't much on readin character by lookin into a man's face, but you don't look like sitch a dog-goned fool as to believe the sort of stuff you're

round the counter at the cans of hunny which the stranger was a standin with his back to them, and had been samplin it with a little pine paddle; and just as Jim stopped talkin, Zed handed him the paddle with a sample on it, and, says Zed, "That's about as much like the sample in the bottle as tar is like molasses. I never tasted glucose; but that tastes mighty like the bee-papers tells about it. Say, Jim, how much of that would a fellow have to eat to make him want to steal from his grandmother?"

You just ought to have seen that stranger grab to get the cover on that can. He looked like he would like to eat up Zed, but he didn't dast to say any thing.

"I guess I don't want to buy any hunny today," says Nat.

It wasn't long before the stranger was a makin tracks for the next town.

JAKE SMITH.

SUPERSADING QUEENS.

Question.—Is it advisable to let a queen become more than two years old before superseding her with a young queen?

Answer.—Some believe it advisable to supersede all queens over two years old, unless perhaps they except those most valued for breeding-purposes, such claiming that older queens, as a rule, are not as prolific as young queens; hence it often happens that older queens fail at a time when the work of storing surplus is interfered with. All this sounds very nice; and if time hangs heavily on any bee-keeper's hands, here is a chance for such a one to pass away his time with the idea that he is doing that which tends toward a greater financial gain; but with the average bee-keeper it is usually more work than he can do during the summer months, let alone any work of a doubtful nature.

There is no question but that we want, for comb-honey production, either very prolific queens or a

brood-chamber not of a size which will require the most prolific queen to strain every nerve to keep it filled with brood. I believe it more profitable to adjust our hive system to the average queen than to practice superseding queens, as some do. A queen should be allowed to remain as mother of a col-

"WHEN YOU SEE HUNNY NOWADAYS YOU DON'T KNOW WHETHER IT'S HUNNY OR NOT."

a talkin. If it's a good thing for the bee-keeper when there's a short crop to have the supply keep a goin with glucose, do you suppose the chaps that do the mixin will be so everlastin accommodatin as to haul off from the market when the bees turn in a full supply?"

While this talk was a going on, Zed had got

ony as long as she retains her fecundity; for prolificness, not age, should be the test in this matter. I never supersede a nice queen, no matter how old, until she shows signs of failing powers. We want queens for the eggs they lay; and for that reason, power of production, and not age, is the rule to follow. I would not keep even a *young* queen, if she did not lay up to a fair average, for there are a few queens that are not prolific enough to keep four frames supplied with brood as they ought to be; and where I find such, I always give their colonies something better to take their place. However, such queens as this last are the exception and not the rule; for the bees do not often allow such queens to remain in the hive long, especially if they are of the Italian variety. After experimenting in the direction of superseding queens for years, I now decidedly prefer to leave it to the bees to decide when their queens are worn out, unless, by outside observations, I believe they are holding on to some unprolific young queen. As a general thing, the bees will make fewer mistakes in directing this delicate matter than the wisest apiarist is likely to make. I have had queens that were five years old do good duty till the commencement of their sixth year, when the bees would supersede them that autumn, the same as they often do in the autumn, with queens commencing in their second, third, or fourth year.

WAXING KEGS AND BARRELS.

Question.—What is the best method of waxing kegs and barrels for holding extracted honey? and should all barrels and kegs be waxed when used for storing honey?

Answer.—Before waxing any keg or barrel it should be kept in some dry hot room for two or three weeks till thoroughly dried out; in other words, the barrel should be as dry as it is possible for it ever to become, at the time of waxing. Having it thus dry and warm, the hoops should be driven as tightly as possible, and short nails, that will not reach through into the inside of the barrel, driven a foot or so from each other at the rear of the last hoop, so that the hoops will not get misplaced in handling. Now pour in, at the bung-hole, from five to ten pounds of very hot melted wax, or, what is preferable, paraffine, and quickly drive in the bung. Now turn the barrel over and over, and twirl it around on each end till you are sure all the cracks are filled. Then take out the bung, pour out the wax, and heat it over again for the next. Be careful to see that the bung does not strike you when taking it out, as it will often fly with great force if the wax is as hot as it should be.

Having told how to wax kegs and barrels, allow me to ask, in answering the latter part of the query, why not use those made of soft wood, which needs no waxing? Leaky kegs and barrels can never be made entirely safe by

waxing them. The shrinking and swelling of the wood, as exposed to wet and dry, will break the wax; and sometimes a heavy jar, when moving the barrels, will crack the wax and start them to leaking. Good workmen can make tight vessels, and they cost no more than leaky ones. A barrel or keg properly made of the right kind of wood needs no waxing, and the waxing is quite expensive at best.

FLAVOR OF EXTRACTED HONEY.

Question.—What is the best plan to preserve the flavor of extracted honey?

Answer.—To give extracted honey a fine flavor it must be thoroughly ripened. While some have evaporators, both sun and other, which they run extracted honey through or over, that has been extracted in its thin or green state, till it is of nice quality and consistency, as well as having an excellent flavor, yet, in my opinion, no honey has quite as nice flavor as does that which has been left on the hive till the end of the season, the bees having been allowed to ripen it till it is so thick that it will almost stand alone after being taken from the comb. Of course, it is more work to extract such honey; but by keeping it in a room whose temperature is nearly or quite 100°, for four or five hours, it can be extracted very nicely. When extracted, honey should be stored in tin or earthen vessels, and kept in a dry warm atmosphere that is free from odors. Loosely cover and let it stand in this warm dry store-room till all the air-globules have disappeared, the scum that arises being skimmed off, when the honey can be put into glass or tin vessels, ready for sale or family use, and it will retain its fine flavor for years if kept in a proper place.

THE PURITY OF CALIFORNIA HONEY, AGAIN.

Editor Gleanings:—The assertion was made by one of your correspondents, in the Oct. 1st number, that half of the honey in California is adulterated. I am sure it can not be true, and does great injustice to California. I live in the center of one of the largest honey sections in the State, from which quite a number of cars have been shipped, and where there is still in the hands of the bee-men, at the present time, 120 tons, not 1 lb. but is pure honey, and they are holding it at 4 cts.—a price at which, even if they wanted to, it would not pay them to adulterate it. We don't need to adulterate, as our bees work seven months in the year, and the honey rolls in a steady stream, keeping the bee-men busy taking care of it. There may be, and probably is, a little, that, after it reaches the city, is adulterated; but when we

get our bee-keepers' associations a little better organized we will look after them, as we have a law in this State, if we enforce it, that will prevent their calling it honey if it is adulterated. The great bulk of our honey leaves the State as pure as that found by Samson in the carcass of a lion, and I know it is ever so much nicer.

S. B. HOLTON.

Selma, Cal., Nov. 8.

THE ATLANTA EXPOSITION; SOMETHING FOR BEE KEEPERS WHO EXPECT TO ATTEND.

Inclosed please find card and circular of Mr. Smith, whom I am glad to recommend to all bee-brethren as a sincere Christian gentleman, a native Georgian whom I knew in Florida. All who call on him will be kindly treated. It will be greatly to their advantage to call on him before going elsewhere; within reach of depots and postoffice, in the very heart of the city, and close to the highest-rate hotels for those who want to pay higher prices. Street cars to exposition, 5 cts. I consider myself fortunately located—much better than I had hoped or expected.

F. DANZENBAKER.

Atlanta, Ga., Nov. 16.

If those coming to Atlanta, Ga., during the Cotton States and International Exposition, will write me how many in their party, and what kind of accommodations wanted, and send from some pastor of a church, superintendent of Sunday-school, president of Young People's Society, or responsible person, a statement that they are ladies or gentlemen, I will furnish such accommodations for them. I have many homes of the best and most wealthy Christian citizens of Atlanta opened for guests thus recommended.

Thieves, pickpockets, and robbers of all kinds will be here from everywhere. These will get homes where they can be admitted so they may do their work. The city will be crowded with people all the time; but if you send me your application early I can get you in a home free from this class.

Write your full address, number in the party, time expected to stay, sex of each in party, and of what church and society you are a member.

12 North Broad St., Atlanta, Ga. WM. B. SMITH.

CREOLINE A CURE FOR FOUL BROOD.

Some few years ago I saw an article in a Los Angeles paper, written by a man in Germany, who had used creoline with much success for curing foul brood. As I had been much bothered with foul brood I made up my mind to try creoline, although I had very little faith in it. When I started using it in October or November, foul brood was very bad throughout my whole apiary. I just sprayed my bees at the entrance to the hives, and did not examine the hives, as I did not doubt that I should have to clean them thoroughly next spring. But when I examined the hives in the spring I found them entirely free from foul brood. I have been troubled very little since, as I use creoline whenever it appears.

Directions for using.—Drop from 25 to 30 drops of creoline into one quart of pure soft water, and with this spray the bees at the entrance during the warmest part of the day, every second or third day. Repeat this five or six times. Also spray combs. I use an atom-

izer with coarse spray for entrance, and the fine spray for combs. The best time to spray is in the fall, right after the honey season is over, as the creoline has a tart taste, and may affect the honey if used during the honey season.

The apiary which had the foul brood so bad, but which is free from it now, made this summer 412 lbs. of honey, extracted, to the hive.

Valle Vista, Cal., Nov. 7.

HENRY OTTO.

[I don't have much hope, myself, that *real* foul brood can be cured so easily; but then, I hope some one will try it and report.—Ed.]

"PETRIFIED HONEY-COMB.

Is there any such thing as petrified comb? I found a stone about as big as a fist. I broke it in two with a hammer. Inside it looks like a box of comb honey, but smaller, and pressed together. It must have originated with bees or some insect like them. I never heard of petrified comb.

HENRY BRESSER.

Toledo, O., Nov. 12.

[The stone you found is probably what is more correctly called honey-comb coral. Prof. Cook, in his "Manual of the Apiary," page 157, has this to say of it:]

A very common fossil, found in many parts of the Eastern and Northern United States, is, from its appearance, often called petrified honey-comb. We have many such specimens in our museum. In some cases the cells are hardly larger than a pin-head; in others, a quarter of an inch in diameter. These are not fossil honey-comb, as many are led to believe, though the resemblance is so striking that no wonder the public generally are deceived. These specimens are fossil coral, which the paleontologist places in the genus Favosites, favosus being a common species in our State. They are very abundant in the lime rock in Northern Michigan, and are very properly denominated honey-comb coral. The animals of which these were once the skeletons, so to speak, are not insects at all, though often called so by men of considerable information.

THE TEN-FRAME IN THE LEAD.

We here in this part of Virginia go in for the ten-frame L. hive. There were two parties manufacturing hives here, the one 8 and the other 10 frames. Both were talking up their merits. The eight-frame man is now out of business, and the ten-frame man has the whole field to himself. I myself use the Manum hive of 11 frames and double story for extracted, and single story and section for comb. Give me a good brood-nest, and, consequently, a large colony, and if there is honey to be gathered they will get there.

S. H. BLOSSER.

Dayton, Va.

MORE THIEVES; THE HOUSE-APIARY FOR THE REMEDY.

I think the house-apiary for bees, described in GLEANINGS, is just the thing, and here is a child that will have one if it all goes well. The note about petty thieves was right to the point. If I had had a bee-house this season it would have saved me \$300 besides what I fed the bees. I got a sample feeder from Boardman a few days before it occurred, and I set it to work, and it works like a charm.

C. H. WIGGINS.

Stimson, Mich., Nov. 4.

THE *Kansas Bee Journal* has been merged into the *Rural Kansan*.

I EXPECT to attend the Chicago convention, January 9, 10, and perhaps the convention of the Ontario Bee-keepers' Association. Now that I have so far recovered my health, I have made up my mind to make up for lost time.

OUR old correspondent J. A. Green, who formerly wrote for these pages more frequently than of late, has finally deserted the ranks of bachelorhood and has taken unto himself a "queen" to reign over his house. I told him at the North American, at its meeting in Chicago last, that such a good-looking bee-keeper as he ought to have a "better half." Although he didn't take up with my suggestion then and there, perhaps he has been conning it over as a sweet morsel under his tongue.

THE BEE-KEEPERS' CONGRESS meets at Atlanta, Ga., Dec. 4 and 5. It is in no way connected with the North American, nor is it expected to interfere with it. Dr. Brown, who is the prime mover, says of it in the last *American Bee Journal*:

"It will simply be a sort of informal meeting of representative bee-keepers from different portions of America, to deliberate and discuss questions that concern the present and future interests of the industry of bee-keeping. Essays will be read by W. S. Hart, O. O. Poppleton, Dr. Peete, G. W. Demaree, Messrs. Dadant, Doolittle, Van Deusen, Mrs. L. Harrison, and others.

"The City Hall has been secured for the meeting. Excursion rates to the Exposition can be obtained from all the principal towns and cities. Rooms can be had at the Jackson Hotel (near the depot, and one block from the place of meeting) for 75 cents per day, and 50 cents for meals. The Jackson is a new hotel, and good place. Those who want less rates can find them at the Adkins House, 12 Broad Street."

The congress that met at New Orleans during the exposition was a grand success. At this meeting there was the largest gathering of bee-keepers that I believe ever assembled in this country, if we except the meeting of the North American at Chicago during the World's Fair. If the congress at Atlanta shall be any thing like its predecessor in the general attendance, in the presence of representative bee-keepers from all over the land, and in enthusiasm, we shall hope for a grand meeting and a good time. Seeing the exposition itself alone will more than repay the cost of transportation, and reduced rates are offered from all points. A. I. R. expects to be present. He will arrive in Cincin-

nati Monday, the 2d, so as to leave on the 7:30 P.M., via L. & N. He hopes to meet other bee-keepers on the same train.

THAT MOOTED HIVE QUESTION.

NOTWITHSTANDING many of our correspondents seem to be interested in this subject, and that there has been a general request for its continuance, I believe the time is now drawing near when we should draw it to a close. I shall use such matter as we have in type, after which we will devote our columns to other subjects. Much has been gained by the discussion I am sure; and what we have learned has been pointed out in previous editorials. I take pleasure in calling special attention to an article in this number, by R. C. Aikin, which sets forth pretty clearly the conditions under which the larger and smaller hives may give the best results.

THE DADANTS AND LARGE HIVES.

THE Home of the Honey-bees has again been favored with a call from another prominent bee-keeper and supply-man. This time it was C. P. Dadant, the foundation-maker, of Hamilton, Ill. Unlike some of our recent visitors he did not call in the interest of his health to see Dr. Lewis, preparatory to going on to the beef-diet cure. Oh, no! he was the very picture of health. Typhoid fever had left him (as it often does its victims) several notches better in health.

It will be remembered that the Dadants have been the pioneers in the advocacy of large hives—not simply ten-frame Langstroth, but ten-frame Quinby—frames that are $18\frac{1}{2} \times 11\frac{1}{4}$ in. instead of the L. size, $17\frac{7}{8} \times 9\frac{3}{8}$ inch. When I asked C. P. how they still stood on the hive question he replied that they were of the same opinion still. They have tested the matter over and over again on an extensive scale, with whole apiaries, only to find in every case that the large Quinby gave the best results. They had no "ax to grind," as it made no difference to them which style of hive or frame was adopted.

I told him it must be somewhat encouraging to them to note that, while they at first apparently stood alone, now a change toward their views and practice seemed to be slowly coming on. Yes, he said they long ago decided that time would vindicate their position.

In France the large Dadant-Quinby hive, among intelligent bee-keepers, is almost the standard.

The Dadants keep now only about 350 colonies. They have kept as many as five and six hundred. Besides their large foundation business, and the bees, they are extensive growers of grapes. C. P. looks after their business interests while the elder Dadant attends more strictly to bee-literature. While he has not written much of late for the bee-journals of

this country, he is a constant contributor to the French journals; and in that country, if I am correct, is counted as the highest authority.

By the way, the junior Dadant has lately come into the proud distinction of "father-in-law." It seemed rather strange to him, but he was getting used to it. His nineteen-year-old daughter has gone with a handsomer man than he. Congratulations to the new couple.

Although the Dadants, in a business way, meet us in sharp competition, it is a pleasure for me to record that there are no bee-keepers whose friendship we value more highly. Their competition has always been fair, and their business deals strictly honorable.

REPORT OF THE COMMITTEE ON AMALGAMATION.

The committee appointed by the last meeting of the North American at Toronto, to report on a plan of consolidation of the two organizations, the North American and Beekeepers' Union, have been hard at work; and now, after much correspondence, are ready to submit their report, which is as follows:

We, the Committee appointed at the North American Beekeepers' Convention, held at Toronto, Ont., September 6th, 1895, on the proposed consolidation of the North American Beekeepers' Association and the National Beekeepers' Union, report as follows:

The duties and powers of the Committee are clearly defined in the Resolution which authorized the appointment of the Committee, which after prolonged discussion was unanimously adopted. This resolution was as follows:

RESOLVED, That a Committee of seven be appointed to take into consideration the proposed amalgamation of the National Beekeepers' Union and the North American Beekeepers' Association, and to arrange terms therefor, with full power to perfect the same so far as this Association is concerned; and to report through the bee-periodicals, as soon as possible, the present President of this Association to be one of the members of that committee.

The Committee met and organized, and unanimously adopted the following address:

To Officers and Members of the National Beekeepers' Union, GREETING:

Being co-workers in one common cause—the welfare of the bee-keeping fraternity, and the advancement and defense of the pursuit of apiculture in America—we are authorized by the North American Beekeepers' Association to offer you the "hand of fellowship," congratulating you on your efficient organization and successful work during the ten years of your existence.

As there is no necessity for the existence of two organizations to accomplish the work which can easily be done by one, we propose a consolidation of our two societies, for the purpose of creating a closer "bond of union" between apiarists, and saving them the extra expense of membership in two bodies in order to gain the benefits and advantages which one can bestow, when united for that purpose.

Ever realizing that "in union there is strength," we offer you any portion of our name you may desire to appropriate.

We offer you our grand history and work accomplished during the past quarter of a century.

We offer you our members, in every State, Province, and Territory of North America, and, so far as we can, we promise their co-operation in all measures looking to the advancement of the interests of the pursuit, and a continuance of the glorious record you have made in the ten years of your successful existence.

All we ask in return is, that you add, to your al-

ready efficient organization, similar annual conventions to those we have heretofore been holding, at some convenient time and place, and, if possible, that you devise some equitable system of delegation so as to make such thoroughly representative, competent to act for the entire membership.

We desire that this proposition be submitted to your members, together with such constitutional provisions as may be necessary to effect the consolidation and provide for annual meetings, so that a full and free vote upon the same may be taken at your next annual election of officers, and hope that this proposition may be accepted—that being the only necessary step to unite us both into one strong and well-equipped organization. If the consolidation is effected, it would be desirable for it to go into effect as soon as possible.

THOMAS G. NEWMAN, Chicago, Ill.

F. A. GEMMILL, Stratford, Ont.

J. T. CALVERT, Medina, Ohio.

M. B. HOLMES, Athens, Ont.

A. B. MASON, Toledo, Ohio.

ENGENE SECOT, Forest City, Ia.

R. F. HOLTERMANN, Brantford, Ont.

CONSTITUTION OF THE NORTH AMERICAN BEEKEEPERS' UNION.

ARTICLE I.—NAME.

This organization shall be known as the "North American Beekeepers' Union," and shall hold meetings annually at such time and place as may be designated by the Board of Directors, due notice being mailed to all members at least 60 days previously, and published in the bee-periodicals of the United States and Canada.

ARTICLE II.—OBJECT.

Its object shall be to protect the interests of its members, to defend their rights, and to disseminate apicultural knowledge among the people.

ARTICLE III.—OFFICERS.

Sec. 1.—The Officers of this Union shall consist of a President, Vice-President, Secretary, Assistant Secretary, and Treasurer, whose duties shall be those usually performed by such officers.

Sec. 2.—The Secretary shall be General Manager, and shall have charge of the executive work of the Union, under the advice of the Board of Directors.

Sec. 3.—The officers shall be elected by ballot, and hold their several offices for one year, or until their successors are elected and qualified.

Sec. 4.—Nominations for officers shall be sent to the General Manager before the first day of November in each year, who shall cause the same to be printed in the bee-periodicals—and shall be printed and mailed by Dec. 1, with the necessary ballots, to every member who has paid dues for the previous year.

Sec. 5.—The Treasurer shall furnish a bond of \$2000 (to be approved and held by the President), for the faithful accounting of the funds of the Union, and shall pay out the funds only on vouchers signed by the President and Secretary.

Sec. 6.—The terms of office shall be for the calendar year, and the polls shall close on the last day of December.

Sec. 7.—Each annual meeting shall, by majority vote, elect a Chairman and Recorder from those present, to preside over the meeting, and prepare a suitable report of the proceedings for publication in the bee-periodicals as soon as possible after the close of the meeting. Any member whether an officer of the Union or not shall be eligible to these positions.

ARTICLE IV.—BOARD OF DIRECTORS.

The officers shall constitute a Board of Directors, which shall determine what course shall be taken by this Union, upon any matter presented to it for action, and cause such extra assessments to be made upon the members as may become necessary; provided that only one assessment shall be made in any one fiscal year, without a majority vote of all the members (upon blanks furnished for that purpose), together with a statement showing good reasons for another assessment.

ARTICLE V.—MEMBERS.

Any person may become a member by paying to the Secretary an entrance fee of \$1.00, for which he shall receive a printed receipt, making him a member of the Union entitled to all its rights and benefits until the 31st day of December, following. The annual fee of \$1.00 shall be due on the first day of January in each year, and MUST be paid within three months in order to retain membership in this Union.

ARTICLE VI.—FUNDS.

Sec. 1.—The funds of this Union shall be used for any purpose in the interest of the pursuit of bee culture, when approved by the Board of Directors; and to pay the legitimate expenses of the Union.

Sec. 2.—The salary of the General Manager shall be determined by the Board of Directors, but shall not be more than twenty (20) per cent of the gross income for each fiscal year.

ARTICLE VII.—AMENDMENTS.

This Constitution may be amended by a majority vote of all the members, provided that all proposed amendments shall be presented in writing, signed by three members, and sent to the General Manager before the first day of November, so that they may be presented in his Annual Report.

It seems to me the committee, considering the fact that its various members live hun-

dreds of miles apart, have done their work faithfully and speedily. While I hardly see how the proposed constitution could be improved, it is now submitted to the larger wisdom of bee-keepers at large for suggestions. It may occur to some, for instance, that the membership-fee should be reduced, as that has been advocated some; but the committee, if I am correct, feel that this is too bold a step just now. This is, perhaps, a question that should be left for the future.

THIEVES AND MISCHIEVOUS BOYS AT OUT-YARDS: HOUSE-APIARY THE BEST SOLUTION OF THE PROBLEM.

SEVERAL times our basswood out-apiary has been visited by thieves; and a few days ago some boys, bent on mischief or malice, actually overturned several of our two and three story colonies. It could not have been the wind, because there was intelligent (not to say mischievous) design in their madness. For instance, one hive—a three-story one—was turned bottom upward, and set back exactly on the same spot of ground. Strangely enough, although there was lots of honey, none was stolen; and, again, tools were scattered all over the apiary. Happening by on my bicycle I discovered this reversed order of things, and, as luck would have it, I must have come around shortly after the boys left; for robbers had not yet gotten at the exposed tops of hives from which the covers were removed. Is it possible I happened to scare them off before they had time to appropriate the honey?

The apiary is located among the trees a little ways back from the road, and the next house stands a little excluded from the view.

Well, what did I do? Simply set things to rights. Those big double and triple deckers I simply rolled like so many sugar-barrels, over and over and over, until succeeded, after much effort, in getting them near their old location: then I boosted, and grew red in the face, until I got them back where they were. "My!" thought I, as I got the last hive back to its place, "it must have been lots of fun for those boys to tug at them, if they worked as I did," for they were pretty well filled with honey and bees. You see we had not yet fixed them over for winter.

But how about the bees, the combs, and the frames? The latter were Hoffman, of course, and stayed right where "they were at;" and after the hives were back in their places you would not know, by looking at the bees or combs, that they had been subject to such rough treatment. So much for self-spacing Hoffman frames. What would have been the result if they had been the old-fashioned loose unspaced kind?

THE REMEDY.

At first I proposed inserting a notice, offering a reward for the arrest and apprehension of

the guilty parties, for the penalty, in this State at least, is very heavy for in any way unlawfully meddling or tampering with hives of bees; but on second thought I concluded it would do no good, and perhaps direct the attention of other malicious persons to the apiary in question.

In mentioning the matter to F. A. Salisbury he told me that not only his home but his out bees were in a house-apiary—just such a one as was recently described on page 662 of our issue for Sept. 1st. He could not only handle twice as many colonies with the same labor because every thing is so handy, but he could lock it up, secure from petty thieves and mischievous boys. The honey could be taken off at the proper season, and stored in the building, and he could at his leisure come and take it away.

Speaking of the house-apiary in this connection reminds me of the quick way of feeding his bees, and to which he briefly alluded in his article on page 663. Of course, inside he uses for convenience the common out-door hives. These give him the advantage of shifting whole brood-nests or supers; and then he can, when desired, bring an outdoor colony inside, and, *vice versa*, shift an inside colony to the outside. Instead of regular bottom-boards he uses shelves that are part and parcel of the house. In the bottom of this—that is, under each hive—are two grooves that are intended for feed. These grooves, extending outside of the hive proper, and covered with wire cloth as far as they project beyond the hive, prevent the escape of bees. When feeding-time comes, syrup is made in the house by the extractor plan, as given elsewhere. Glass Mason jars are filled full; squares of tin are then laid over, and, last of all, the jars are inverted and set over the wire cloth covering the aforesaid grooves. The tins are withdrawn from the jars now inverted, and the feed runs along the grooves under the brood-nests. The whole work is done inside of the building, secure from robbers and thieves of the human kind (some of our syrup during feeding was stolen also, at our basswood yard). Friend S. says the feeding can be done up in short order; and as fast as the jars are emptied, which can be told at a glance, they may be refilled if the colony requires it. As soon as they are fed they are prepared for winter, which is another short operation.

Mr. Salisbury says he has also overcome the smoke nuisance. By his arrangement he secures a cool pleasant place to work, no matter how hot outside.

I believe I shall not rest till we get a house-apiary at our basswood yard. A few more visits from thieves, to say nothing of the annoyance of having the hives tampered with, and tools stolen, would pay for a good building, in time.

THE SALISBURY TREATMENT; HOW TO PREPARE THE LEAN MEAT.

A LETTER FROM DR. SALISBURY HIMSELF.

Dear Mr. Root:—I notice in GLEANINGS for Nov. 1, page 817, an article on the preparation of "Salisbury steak," which is most decidedly wrong. The writer evidently had no idea of the fundamental principles of causes of the various diseases. The whole reason why the beef is ground is to extract the fiber from the muscle-pulp. This fiber is the very element which causes so much trouble by producing thickenings of various tissues throughout the body, and causing partial and complete paralysis; and it is very essential that it should be removed from the beef, as far as possible, especially in the cases of those who are very sick.

The following is the correct instruction for the preparation of the beef:

Eat the muscle-pulp of lean beef made into cakes and nicely broiled. This pulp should be as free as possible from connective of glue tissue, fat, and cartilage. The "Enterprise chopper No. X" (10) answers very well for separating the connective tissue from the pulp. When this machine is new the knife should have the sharp edge taken off with a whetstone, so as not to cut the fiber, and the end-plate should not be screwed up too tightly, but left loose, to allow a small space between it and the knife—enough to prevent cutting the fiber, and allowing it to be caught by the knife and by the holes in the end-plate. After grinding half a pound or a pound it will be noticed that the beef does not pass through. This is due to the holes being filled with the fiber, and fiber also collecting on the edge of the knife. Take off the end-plate and knife, and remove the fiber, and proceed as before.

In order to get out all of the fiber or connective tissue it is necessary to unscrew the end-plate and remove the fiber several times, and to put the beef through the machine from three to five times, according to the quality of beef. Previous to chopping, the fat, bone, tendons, and fasciæ should all be cut away, and the clean muscle cut up in pieces an inch or two square. Steaks through the center of the round are the richest and best for this purpose. Beef should be used from well-fatted animals that are from four to six years old.

The pulp should not be pressed too firmly together before broiling, or it will taste livery. Make the cakes from half an inch to an inch thick. Broil slowly and moderately well over a fire free from blaze and smoke. When cooked, put it on a hot plate and season to taste, with a little butter, "pepper and salt."

If you follow these directions you will have fine cakes free of fiber—tender, and in all a complete article of healthful diet.

J. H. SALISBURY.

170 W. 59th St., New York, Nov. 15.

I am sure, doctor, we are all of us greatly obliged for these timely words from the discoverer and originator of this method of treating disease. Ernest wishes me to emphasize the fact that there is great need of an intelligent physician to direct, especially where the disease is a serious one, and where it is necessary to come down to an absolutely lean-meat diet and nothing else. I have known many cases where people were greatly benefited by simply using more meat and less vegetables, especially avoiding the excessive use of sugar and other sweets. I can remember all along during the past 25 years, especially when my work required me to be in the office more than usual, Mrs.

Root would again and again say something like this:

"Look here, dear husband, you are getting into trouble just because you have neglected to eat meat of late, and you are eating too much other stuff that you should know by experience you can not stand. Now just let me prepare your food, and map out your diet for you for only just a few days, and see how quickly you will come out all right."

Well, she did bring me out all right; but notwithstanding I kept getting skeptical, or suggesting that other things would do as well as meat. By the way, there is one thing that I wish to mention. A great many people say that it might do for others, but it would never answer for them at all. They could not eat it—don't like it, and would starve to death, etc. In fact, when I recently adopted the exclusive meat diet I talked about the same way. In just three or four days I began to like my meat, and I can't remember a single occasion during the whole past three months when I did not have a good appetite, and have eaten with a good relish at least 10 or 12 ounces of the ground meat. When I got to using sirloin meat instead of the ground meat, at first I began to swallow the hard or gristly portions after I had chewed them pretty thoroughly. But I found this did not answer; and since then I have been having a small dish right beside my plate, where I put all hard, tough, and gristly portions, after chewing them enough to recognize what they are. Where digestion is weak or impaired, I am sure all these portions should be carefully taken out of the mouth.

By the way, the publishers of the Salisbury books, Kellogg & Co., 1031 Sixth Ave., New York, or 32 Church St., Toronto, have kindly furnished us a lot of little hints in pamphlet form, entitled, "Who is Dr. Salisbury?" and they give us a very complete history of Dr. Salisbury's discovery, and much other valuable information. We can mail them free of charge to anybody who applies, or you can get them, if more convenient, of the publishers, as above.

EGGS AS A HEALTH FOOD.

Dear Friend Root:—I have read with great interest what you have recently said in GLEANINGS on the subject of health. I have tried using the broiled beefsteak, with excellent results; but I have watched anxiously to see if any thing would be said regarding the use of fresh eggs. There are many people who need a change of diet to help them out of a bad condition of health, but they do not live where they can procure fresh beef every day. Those who live in the country can produce the fresh eggs right at home; and I think that, when properly used, they are very helpful. I have found that a piece of toasted bread and two or three poached eggs make a breakfast that seems to agree with a disordered stomach as well, or nearly so, as the steak. But eggs should be properly cooked. They should not be boiled hard, but cooked to a jelly, either by poaching or by placing them in boiling water, and then removing the dish containing them to the back part of the stove, where they will cook to the proper degree in about ten minutes.

A man in Vernon Co., this State, died at the age of 106 years. He was asked what had been his principal food. His reply was that he had lived largely on scalded eggs. I know it has been claimed that the use of eggs is against purity; but I believe it is no more true than the claim that lean beef makes people "ferocious."

I should like to know the opinion of yourself and the doctors as to the use of eggs. They are not vegetable food, neither does the procuring of them necessitate the taking of life.

Browntown, Wis., Nov. 6. HARRY LATHROP.

Friend L., I have omitted to say that we are permitted to have the white of an egg with our beef-diet occasionally. As it is principally al-

bumen, and contains neither starch nor sugar, it is, I believe, almost as free from objection as the lean meat itself. I presume, however, it would not answer for a steady diet, like the lean meat. With most patients the yolk is objected to. I think I have heard Dr. Salisbury say that it contains sulphur in considerable quantities; and where there is a disposition toward gravel or mineral deposits in any part of the system the yolk of the egg should not be used—or, at least, very sparingly. Inasmuch as the use of eggs does not necessitate the taking of life, I entirely agree with you. But in most markets, where one uses eggs for even a small part of his diet, it would be rather expensive—more so, I think, than lean meat.

THAT POTATO PREMIUM.

MAULE'S NEW EARLY THOROUGHBBRED.

Nothing we have ever suggested in the way of a premium has made such a stir as that pound of Maule's Early Thoroughbred potato, offered for one new subscriber. By the way, we are just informed by friend Maule that the price of the potato for 1896 is \$1.50 per lb., post-paid; 3 lbs., \$3.00; 10 lbs., \$7.50. Of course, I am not to undersell him, therefore we can not sell a single pound of potatoes for less than \$1.50; but we are permitted to make every present subscriber to GLEANINGS a present of 1 lb. of the potatoes if he will send us a new subscription. We do this in order to have GLEANINGS introduced in a new locality, new post-office, or even into a new family. Of course, no one would be so foolish as to send us \$1.50 for a pound of potatoes when he could have the same pound for only \$1.00, and have GLEANINGS thrown in *besides*; so if you really want a pound of the potatoes, and do not want to pay \$1.50, why, send us \$1.00, and then make somebody a present of GLEANINGS for the one year. It is a tremendous offer we are making. I am well aware; but it is of very great benefit, as you may readily see, to any publisher who has a good journal (and that means *our* journal, does it not?) to have that journal introduced and read. Sending sample copies does pretty well; but nobody gets acquainted by looking over one sample copy. Your humble servant, A. I. Root, is said to be a little peculiar, and that he has some queer fashions of his own; but after having GLEANINGS a whole year, people generally get acquainted with him and understand him, and they very generally like to keep up the acquaintance—it *pays* them to do so. Now, this is not boasting or bragging, for we are all peculiar to a greater or less extent; and it helps amazingly in this world of ours to get acquainted one with another, especially where there is even a little bit of "hungering and thirsting after righteousness," we will say, on *either* side.

Well, now, since making this offer of mine, unforeseen and unexpected complications have come in. For instance, instead of getting one new subscriber, a man gets *two**; and then some one else wants to know how the *new* subscriber is to get a pound of potatoes, for he

wants it just as bad as the other man. Well, the plain and evident way is for the new subscriber to start out himself and get another new name among some of *his* friends and acquaintances; or if you secure a new name, and the subscriber wants a pound of potatoes also, you can be neighborly and divide up. Tell him if he will subscribe for GLEANINGS, and give you \$1.00, you will give him half of the pound of potatoes. Why, just look here, friends; what do you suppose can be done with a single half-pound of potatoes, or even *less*? When I was down in Missouri, one dark night I blundered into the family of our good friend Yoder. They were all gathered around the supper-table. But, weren't they astonished when they found that A. I. Root was there among them at that late hour of the night! and wasn't there a hustling of the chairs to make room for the editor of GLEANINGS! and didn't they just pile the good things over at my end of the table! Well, the next morning we went out and looked at friend Yoder's garden. I told you about his Prizetaker onions for which he was going to get \$1.50 per bushel. He got the plants started under glass (you will remember) by pulling the windows out of his shop. Now, if you will turn back to GLEANINGS, page 752, you will see what he undertook to do with only 6 ounces of the Craig potato. In fact, we copy his statement from the above page:

The Craig Seedling potatoes you sent me arrived at the postoffice on the coldest Sunday of last winter, and were not taken out till Monday. They were frozen, all but 6 ounces. I now have 16 hills of the plants, and 60 side-shoot hills. G. J. YODER.

Garden City, Mo., Aug. 6.

Now, here is the outcome:

Friend Root :—The 6 ounces of Craig potatoes mentioned in GLEANINGS, page 752, produced 87 lbs.; the main plants, 45 lbs.; side shoots, 42. The latter part of September was very dry, but the side-plants remained green until frost. G. J. YODER.

Garden City, Mo., Nov. 15.

There, friends, you see what Gideon Yoder did with 6 ounces of Craigs—87 lbs., or at the rate of 232 lbs. from 1 lb. planted. But the Craig is a late potato. With this new Maule's Early Thoroughbred potato you can probably get *two* crops in a season—at least, most of us can. The way to do it is being pretty well written up in our various gardening periodicals. And while we are about it we might give right here what friend Greiner says in the *Practical Farmer* for Nov. 9, in regard to the Thoroughbred in his locality:

Blood will tell.—This is what Mr. Terry tells us in P. F. of Oct. 5, first page. We have tried the same potato of which he speaks, a new early one sent by Mr. Maule for testing. In my own patch, four hills were planted with the two tubers, and the yield was nothing remarkable. A brother of mine made twenty-one hills of his two specimens, and planted them in the field with Carman No. 1, Clapp's Favorite, and Star. The yield of the twenty-one hills amounted to just half a barrel (90 lbs.), or twice as much as Mr. Terry got. The potatoes are of enormous size, and in quality all that any one could desire. Yes, blood will tell. If you plant a heavy-yielding variety, even with careless culture, you will be more liable to get a big yield than when you plant scrub varieties, even with the best of treatment.

He also says, in regard to the Freeman potato, in the same issue, as follows:

The Freeman, I think, has made more friends this year than ever before. It is surely as beautiful a potato as one can ever hope to find, so smooth and clean and uniform. It is also as fine a table potato as we ever had, so white and mealy. Of five competitors for premiums on best peck of table potatoes at a local Western New York fair, three exhibited Freemans, and one got first premium, while another had second. When it comes to "best table potatoes," the Freeman surely takes the lead. We

*If a man gets two new subscriptions he gets 2 lbs. of the Thoroughbred potatoes, and so on—a pound of potatoes for every new subscription; and he can work at it all winter if he wants to—that is, so long as the five barrels of potatoes hold out. By the way, our offer on page 841, Nov. 15, a pound of potatoes for subscribing for 1896 and '7, all together, will be withdrawn after you see this. If you do not see this at all, it will be after Dec. 15. You see there are not going to be potatoes enough in that five-barrel lot to go around.

have often complained of "too many and too small potatoes in the hill," as a characteristic of the variety. Such complaints are not heard this year. The Freemans have turned out well all over. I had planted mine in my usual way of seeding—about a half medium-sized tuber in a hill. Yet the potatoes when dug were just about the right size for use or market, few extra large, and almost no small ones. They appear well in the bin. The yield was at the rate of about 250 bushels per acre. What they would have done, if not checked by the long dry spell, is hard to tell.

With the same measure that ye meet withal, it shall be measured to you again.—LUKE 6:38.

The above has been repeated over and over again so much that some of the friends may be tempted to say, "Oh dear me! I have heard that over and over again so many times that it really makes me feel tired to hear it." Yes, this is indeed true; but notwithstanding the sermons and admonitions and grand texts we have in such profusion all about us, through our periodicals, from the pulpit and the prayer-meetings, and in the Endeavor Societies—notwithstanding all this, we are selfish and greedy still. Evidently, we do not believe it. We preach one thing and practice another. This matter has been brought vividly to my mind since I have been in the potato business by the subject of barrels. How much is a barrel? The word "barrel" has come to mean so much or so little that several times I have been tempted to think we had better abandon barrels and use bushel boxes—the Terry bushel box, for instance.

There are several reasons, however, why boxes can not well take the place of barrels. First, one man alone can handle a heavy barrel easier and quicker than he can handle a box of the same weight. He can roll it along the platform or he can roll it up a plank into a wagon. Transportation companies, I believe, make a distinction in rates of freight on goods in barrels over those in boxes. Again, a barrel properly hooped will stand more hard usage than a box of about the same capacity, weighing the same number of pounds. That is, a barrel weighing 20 lbs. will hold more goods, and keep them in better shape, than any box that has ever been made, of similar weight. Apples and potatoes, to ship without being bruised and mashed up, should be pressed in solid, so they can not shuck about in transit; and this can be done with a barrel better than with any sort of box. Finally, my impression is that a barrel can be made for less money than a box of the same capacity. For some time to come, probably, barrels will be used for shipping all sorts of produce and a great variety of goods.

Years ago we used to call a barrel three bushels; and we used to have good fat plump-looking barrels. They did not look starved, and straight up on their sides, like a stovepipe. When I was a juvenile, right across the street from the old schoolhouse, under the limbs of a spreading oak, was a cooper-shop; and that cooper of olden time made good honest barrels. How patiently he explained to each juvenile mind the whole operation from beginning to end, from bringing staves and heading from the piles out in the yard, and making them into nice honest smooth barrels, and all by

skillful handwork, from first to last! Those barrels would hold flour, without having it sift out; or they would hold vinegar—especially when the purchaser said he *wanted* a good vinegar-barrel; and they held a good plump three bushels. I do not remember that our good friend Mr. Coe ever made a small, scanty, scrimped, straight-sided barrel, such as we have nowadays. Well, I can remember later along when there was a discussion in regard to the size of barrels. Somebody complained, who bought a barrel of apples, that there were not three bushels.

"Oh! yes, there is," said the dealer. "Look here; we will measure them up."

"But," says the purchaser, "you don't heap up your half-bushel enough. A barrel of apples and potatoes must be piled clear up."

And here again came discussion. The dealers were not always to blame, because, when a farmer took a load of potatoes around town somebody would say, "Yes, I will take three bushels of potatoes providing you give good measure."

"Well, how good measure do you want?"

And then the buyer piles them on the half-bushel just as long as he can make the potatoes stay on top. This is manifestly unfair—as unfair as the other way; and I have seen grocers bantered; and where they happened to be meek and inoffensive sort of people, some customers would impose upon them by demanding all that would lie upon the measure. Can you blame the grocer for wanting some measures that might be heaped up to suit, and not contain over a real peck even then?

Well, by and by it transpired that there was an agreement, in order to settle all these jangles, that a bushel of potatoes should weigh so much, say 60 lbs. My impression is, that the laws of the State of Ohio have fixed a bushel of potatoes at the above weight; and we have also tables giving the weight of grains as well as vegetables that shall constitute a bushel. One unfortunate phase of this matter is, however, that different States fix the bushel at different weights; and on buckwheat the weight of a bushel varies as much as three or four pounds. It seems to me as though this thing need not be, for somebody has to be the loser when grains have to be shipped from one State to another. It has been urged that, when potatoes are just dug—especially if they are a little damp, and some of the soil is sticking to them, weighing is not fair either; for 60 lbs. of potatoes, just as they come from the field, will weigh only 57 or 58 lbs., or perhaps less, after they have been kept over winter. This may be true; but selling by weight is very much better than letting every one who is of a greedy turn of mind give half a bushel even full or rounded up according as he happens to be buyer or seller.

For many years we have been in the habit of purchasing second-hand barrels at the groceries and stores; and we find barrels that will hold as little as two bushels and some that will hold as much as four, and even more. Since we have got into the potato business we have found that, in order to do business in a square honest way, we must define in our price lists that a barrel of potatoes is supposed to be 11 pecks; and then we usually put in parenthesis, by way of safeguard, "(165 lbs.)." But even if our barrels are made at a barrel-factory, they do not seem to be uniform in capacity. A lot of 1000 may *average* about 11 pecks; but some of them will be likely to lack half a peck while others will go half a peck over. May be there are barrel-factories that do better than this. I hope so. Sweet potatoes, as they come from

the South and East, are evidently put up without weighing at all. If you specify, however, in making an order, that you will take 10 barrels of potatoes providing they average 150 lbs. to the barrel, you will likely get it; and I think this is the best way to do business. It is some trouble to remember and specify, every time, what you expect to have when you agree to pay a certain price; but it has the effect of avoiding jangles and disputes, and is very much pleasanter all round. The man who is careful to build up a good name, and keep his good name after he gets it, will be very apt to comply with all your conditions if he expects your order. In our own practice we put 165 lbs. in a barrel—or, rather, the boys have instructions to put in 167 lbs., so as to be a little over rather than under; and then if the barrel is not full we fill up with straw or shavings. If a customer orders three barrels we sometimes put the whole into only two very large barrels. This is generally satisfactory, providing a card of explanation gets there before the potatoes do. If our packers neglect to do this on the invoice, sometimes the customer will write back:—

□“Look here, Mr. Root. □I ordered and paid for three barrels of potatoes; but I found at the station only two; and the agent says there are only two on the bill of lading. I have been told you are a good, straight, honest man; but it looks as though I had been humbugged in this my first deal.”

Most of you, especially those who are old in business, will blame the man for being in haste to think evil; but when I look abroad and see how many there are who send away their hard earnings, and get swindled out of part or all of it, I confess I feel a good deal of charity for those who are in haste to think they have been cheated. A good many times I have felt like giving almost the whole business world a good shaking—that is, if I were equal to the task. Do you ask why I would shake it? Why, because people do not *talk* more and *explain* things better. A good many hate to write a letter. They can not even take a postal card and pencil, and say: “You will find your three barrels tightly packed in two very large barrels.” Now, this much on a postal might save a jangle that would cover pages of foolscap later on. The illustration I have given is a very plain and simple one; but in business matters unheard-of complications come up. The dealer is suddenly sold out; sometimes it seems advisable to take just a little liberty in substituting. He may decide, in order to get the order off before freezing weather comes, to put in a higher-priced potato at the price he received, rather than to fail in getting off the order complete. An explanation at the proper time would have made every thing pleasant and neighborly. Neglect to do so makes no end of jangles.

□A good many of us are interested either in buying or selling potatoes for seed, or both; and some of us have more or less to do with the new potatoes that have commanded such high prices when they first came out. Now, where a man gets a high price for an article, say three or four times what potatoes are worth in the ordinary market, for eating purposes, under such circumstances we should expect, of course, he would give good measure. This, however, is not always the case. It would seem at first thought that one who is anxious to build up a trade of any kind would recognize the advantage of advertising his business by giving *good quality* *any good measure*. Some of the new potatoes are very large. Sometimes, besides this, they are long; and for this reason it is

difficult to get as many pounds into a barrel as where the potatoes were *all* either small or some of them small. But where the price is large, and the product large, it would seem as though the seller might be quite willing to purchase larger barrels. Sometimes he does not think of it. He should think of it, however. Not only the success of his business, and his good name that is involved, but other things come in here. A good many people are accused of preaching one thing and practicing another; and if we do not look out, we shall all of us be more or less guilty. There is a class of people, too, who, when they buy, demand the very fullest measure; but when they sell they give the smallest possible measure.

A little item has been going the rounds of the press, to the effect that a farmer's wife brought some butter to a grocer. Said he:

“Madam, I am sorry to say these rolls of butter do not weigh a pound. They are scant weight, every one of them.”

The dealer, however, was not so keen and bright this time as he thought he was. She slipped a package from under her shawl, and held it up.

“My dear sir, that butter was weighed out with a pound of starch bought of you at this grocery. Every roll of butter weighs exactly as much as the pound of starch, *paper and all*. Here it is, and you can try it.”

The woman might have added, in the language of our text, “With the same measure that ye mete withal, it shall be measured to you again;” but I can not learn that she did so.

In regard to barrels once more. Everybody who advertises produce by the barrel should, if he wants to build up a reputation, state how much the barrel contains. Suppose, however, he does not do this—he simply says so much per barrel; and when his customers complain that the barrels are scant, suppose he falls back on his printed prices, saying he didn't say the barrel held three bushels or even eleven pecks, or any thing about it. In one sense he could not be accused of cheating or unfairness; but public sentiment would be against him. There seems to be a general agreement or understanding that any thing that can be justly called a barrel should hold at least eleven pecks, or 165 lbs. I notice in some of the quotations in the papers that a barrel price is given, and then right under it another barrel price for a barrel of 180 lbs. This would be a three-bushel barrel of the old-fashioned kind. I remember of buying a barrel of cranberries; but when we came to retail them they were scant weight. I wrote to the dealer, and he said my order read just one barrel, but it did not say how much it should contain. Had I said I wanted a barrel of cranberries, “*flour-barrel* size,” I should have gotten one that held fully 100 quarts of cranberries. As I did not say so in making my order, I had no redress.

Now, friends, this way of doing business may be all right according to law, but it is not right according to “gospel.” A man who is a professor of religion, and who claims to gauge his life, business, and every thing else by the standard of Christ Jesus, should be ashamed of any such logic. If such a transaction as this should be made by any of his clerks, he should, as soon as he finds it out, make it good whether he loses or gains financially. He should recognize that every thing of this kind tends to dishonor more or less our Lord and Savior Jesus Christ; and this should be of more importance than every thing else in the world besides. Saving property or money, or coming out whole in a transaction of dollars and cents, should sink into insignificance compared with

holding up the standard of the Christian religion. But we do *not* lose by shunning "even the appearance of evil." These little transactions or little inconsistencies tell in a way that no one can comprehend. They tell away off into the future; and when a man once gets a reputation for doing not only all he agrees to do, but all that might be reasonably implied, it is worth more to him than money in the bank; it is worth more than the backing of influential friends; it is worth more than to be a *millionaire*, for it is something that endures through time and eternity.

Perhaps we need such lessons often to help us remember the golden rule. Years ago I decided that it is an excellent thing to be very careful of one's promises; but after having made a promise, either verbal, written, or printed, either in private or public, once having made a promise or agreement, be very sure to do *all* you promise, and, as a rule, just a little more, in order to shun even the appearance of evil.

BATTLE CREEK, MICH.

I was greatly interested, as you may know, in going through the hospital—an immense building which stands near the sanitarium. I can not begin to tell you about all I saw there, but I will mention some things. One room, for instance, is devoted to glass bottles and globes containing tumors that have been removed by surgical operations during years past. There are hundreds of them. They are from the size of an egg up to that of a bushel basket. A complete history of each case was kept on file for reference. I asked my guide, Will K. Kellogg, a brother of the doctor, if errors in diet were probably the cause of the tumors that are becoming so alarmingly prevalent.

"To a certain extent, Mr. Root; but errors in dress are a far larger factor, without question, in producing tumors."

"Errors in dress?" said I. "Do you mean tight lacing?"

"Yes, and that same fashion of cramping the body in other ways. The reason why tumors are more prevalent among women is probably because they are more apt to cramp themselves by their clothing."

Dear friends, does not the above indicate a terrible state of affairs in such an enlightened nation as ours?

Dr. J. H. Kellogg, of Battle Creek, is probably one of the foremost surgeons in the world; at least, so far as I know, he is generally accorded that credit. As my visit happened to be on the regular operating-day, I was, by the courtesy of friends Keck and Kellogg, invited to be present during one of the most critical and difficult operations. Adjoining the operating-room was a little room called the chapel. Here, the surgeons, together with the nurses and students, all meet for a brief season of prayer before undertaking any operation that may have a fatal termination. As I looked into that little room I could not but breathe a prayer that the time might come when every surgeon and every physician in our land, who takes human life, as it were, in the hollow of his hand, could have the spirit in his heart of asking the great God above to give him wisdom and guidance.

The room prepared specially for surgical operations is lighted by skylights from above, so that every facility that the best and strongest light can furnish is at hand. There were three or four surgeons present, and perhaps half a dozen nurses, belonging to the hospital, and I was at once struck by the intelligent and cheerful appearance of the nurses.

The subject to be operated upon was a woman. What could be more fitting than that gentle Christian women should be all round about her to assist in every way they could, not only in sympathy, but in kind womanly attentions and touches? Just above the operating table was a little gallery for the use of medical students. All the nurses, all the doctors, all the students, were covered with a white robe or gown. These gowns enveloped the whole body, even to the feet and head. Their office is to protect the patient from any microbes or bacteria that might accidentally be brought in on the clothing of some one present. Your humble servant found a place among the medical students, enveloped in his robe like the rest. At my elbow was a shorthand writer to take down every particular in regard to the case, and to note every word, explanation, and direction given by Dr. Kellogg, the operator.

The patient was suffering from a diseased kidney. She had been operated upon before; but in order to save her life it was now deemed best to remove the diseased member entirely. Hot water or boiling water was used everywhere as a precaution against blood-poisoning. The knives and all the instruments were thoroughly cleansed with boiling water. Perhaps it may be news to some of you, that, unless this great and extreme care is exercised in cutting into the human body, the surgeon may do more harm than he does good. The medical fraternity at Battle Creek understand these things probably as well as anybody in the world, for they have a corps of expert microscopists, entomologists, and expert scientists in every thing pertaining to bacteria and fungoid growths. Great quantities of lukewarm water were first used to wash out the diseased portion of the body. The patient was given chloroform by means of a delicate apparatus that was new to me. Dr. Kellogg proceeded very slowly and cautiously. At first he gave us a little running talk by way of explanation; but when the discovery was made that the diseased kidney was entirely enveloped and covered up by growths of tissue and fat, then he finally explained to us that it was a very difficult and dangerous case.

In cutting away this abnormal growth, the blood came more and more, for it was interlaced with blood-vessels. The attendant nurses supplied lint and bandages to take up the blood, and the warm water was applied almost incessantly to wash away the blood so the doctor could see where the point of his lancet was penetrating. He explained to us that one little cut too far or in the wrong direction would be almost surely fatal. Never before in my life did I feel so intensely that these things are all in God's hands after all; that in spite of all the wonderful skill that has been achieved in the practice of surgery, God still holds the slender thread of life in his own hand. I know that they prayed in their little chapel before the work began; but my praying was done (and it was done in real earnest too) while it seemed—at least to me—a question whether the patient could ever survive. Finally, during the most critical portion of the operation, the chloroform seemed hardly adequate. The patient shut her teeth, and there seemed danger that she might choke. I do not know whether

lockjaw sets in at such times or not; but I for one feared it.

One of the bright nurses, however, was right at hand with an apparatus for forcing open the jaws. Then another delicate instrument was brought into requisition, and fastened to the tongue to hold it away so it might not close the opening of the windpipe. During all this time the chloroform was necessarily suspended, and the patient began to suffer terribly. It always troubles me when I can not help in a crisis of this kind, especially, where human life is in peril. Thank God, there was *one* thing I *could* do right then and there. Perhaps I should explain right here that I was told I must not speak nor make any sort of noise, for medical students are often dismissed in a body for failing to keep perfectly silent during a critical case like that. The only way in which I could help was by silent prayer. The quantity of blood that flowed, it seemed to my weak and inexperienced eyes, was enough to kill anybody, and I had about given up all hope, although I still prayed mentally, even if it was with but little faith. A fragment of that little hymn—

I am]weak, but thou are mighty.;

kept coming into my mind. Slowly and carefully the doctor worked. One attachment after another was sundered by the keen steel blade. Sometimes it seemed as if the operator meditated a little before cutting away something that seemed to be in the way. After a long time, as it would seem to me, he finally reached the connection that attaches the kidney to the body. Here he was obliged to stop in order to take a bit of cord, held right ready to his hand, before he had had even time to ask for it, by one of the nurses, and the necessary knot was formed before severing the organ.

Let me say right here that it seemed wonderful the way that his nurses, without a word being spoken, kept holding every appliance for the operation, as one thing after another was needed. Sometimes it was water, given through a small rubber tube; sometimes it was lint or bandages, then it was, every little while, some new surgical instrument for holding the skin, the flesh, and different organs out of the way of the operator. I did not notice the time when the operation commenced. It seemed to me as if it must have occupied toward an hour.

I was to leave on the train at three o'clock. Friend Keck silently moved out, for he was close to the door. I gathered from this that it was about time for me to take my train; but so intensely interested was I that I took the chances of waiting a few minutes longer. I did not see the kidney entirely removed, for it was a very slow and careful operation; but I stood until I was sure the terrible ordeal was almost over; I asked friend Keck to write me the result; but, to confess the truth, I had decided in my own mind it was next to impossible for a human being to live after being taken to pieces and overhauled in that manner; but, of course, I know very little about such things. Almost as soon as I got home, the cheering news came that the patient had rallied and was doing nicely. A little later she bid fair to not only recover, but to recover quickly. Within a week or ten days, if I remember correctly, she was able to sit up; and now she is pronounced almost if not quite out of danger.

By way of conclusion I want to say just a word in regard to the physicians and surgeons of this sanitarium. I feel quite certain that not one of the eminent doctors present at that time was ever guilty of the use of strong drink, or even of using tobacco. They were men whose faith is in God, and who are daily seek-

ing his kingdom and righteousness. The time was when our ministers used to enter the pulpit, saturated with tobacco, and sometimes with something worse. At the present time, however, such things may be tolerated in some of the aged members of the ministerial fraternity, but very rarely among the younger ones. I wonder if the time is not also near at hand, when people will demand for a *family physician* one who has no smell of tobacco about his person, and one who is *pronounced and decided* in regard to the use of spirituous liquors. God speed the day!

TURNIPS AND CRIMSON CLOVER.

We are now gathering and selling some of the handsomest turnips we ever raised in the world, and they cost us almost nothing except the seed. It comes about in this way: When we were cultivating our Corey corn the last time, we sowed crimson-clover seed among the corn, as I have told you. Well, we mixed in about an ounce of turnip seed with 5 lbs. of clover. We wanted to have the turnips so far apart that they would not crowd the clover nor crowd each other, and we hit it to a dot. After the ears got too hard for marketing we just pulled up the corn by the roots, knocked the dirt off against the wagon-wheel, and fed it to the horses and pigs. The ground was cultivated with a fine-tooth Planet once after sowing the seed. We have now a very even stand of large nice crisp turnips; and the crimson clover between the turnips is making great rank dark-green clumps of clover. They are stooling out considerably this fall. The plants lie closer to the ground than ordinary clovers; and I feel sure that, on this account, they are going to stand the winter, especially with the growth they have made.

Right adjoining the Corey corn was a strip of Mammoth Evergreen; but the clover and turnips did comparatively little among that great rank-growing corn full of life and energy. I suppose one reason was, there was so little rain there was not moisture enough to go round, and the corn had possession of the ground in the first place, and naturally resented the intrusion. This corn was saved for seed—at least, a large part of it, so it was considerably later before the corn was cleared off, leaving the turnips and crimson clover to have the whole of the ground. There are a few turnips and some clover that I do not think will amount to much.

Now, in managing in this way, especially where we are going to have a very dry season, clover and turnips had better be put in with some crop that is going to get out of the way pretty early. We sowed some turnips and clover in the same way among our beans; and although this was put in a week later, we have a very good stand of clover and turnips both, because the beans are not so tall, and they were pretty well along toward maturity when clover was put in. By referring to GLEANINGS for Aug. 1, page 605, I see that we did the greater part of our turnip and clover seeding on the 29th of July. We sowed White Egg turnips. Purple-top Globe, and Yellow Aberdeen; and all of them have done splendidly except where they were in the rank strong-

growing corn, as I have told you. Just before Thanksgiving we expect to pull all the turnips, then the clover has "undisputed sway."

NEW VEGETABLES AND PLANTS TESTED DURING 1895.

Our friends will remember that GLEANINGS had considerable to say about the lathyrus silvestris, or flat pea. Well, it has not stood the dronth of the past season as I expected to see it do. Perhaps our hard clay soils are not just the thing for it. It stood the severe winter all right, and furnished a great amount of feed until the severe dry weather set in. I do not think its roots have gone the great distance claimed for it—not at this stage of growth, anyway. So far as we have tried it to feed stock, they all seem to take it readily. Our experiments were mostly made in the spring. Bert Cook, when he was with us, said that, so far as he could find out, it was a success in Michigan at the Agricultural College, so far as producing feed was concerned, but no kind of stock seemed to be very fond of it, and he thought it was going to be a failure in that respect. Sacaline, though it grew up perhaps three feet high, and then produced quite a quantity of cream-colored blossoms, has not as yet had sufficient foliage to make any test of it for feed; but very likely it is getting root so as to make a show another year. At present writing it would seem that neither of these plants is going to be exactly what has been claimed for them.

The bush yam, or vineless sweet potato, that was growing so handsomely, made a fine show of tops, but no potatoes of any account, on our soil; but for that matter we never have had a good yield of sweet potatoes, or yams either, on our ground. Yes, we did have some very good-sized yams, but they were not dry and mealy like the sweet potatoes we get from Baltimore. We tried selling them around town; but all of our customers voted the home-grown were not as good as those shipped in from other localities.

Best of All beans I have reported on before. There seems to be no fault coming out with regard to these; but they are not particularly new.

We have tested several kinds of sweet corn, but do not find any of them enough better than we have, to give them a place in our new catalog.

The Sweetheart melon, mentioned in August, we have thought worthy of a place.

Burpee's Fordhook tomato will also be cataloged for 1896.

We are testing the Marshall strawberry, and think quite likely we shall give it a place in our catalog next July. We have at present, however, no plants for sale.

The Gault raspberry has already received sufficient notice. We think it has come to stay.

On page 499 we copied at length from the *Rural New-Yorker* in regard to Electropoise, and the editor there agreed to test the thing for a period of several weeks. He has done so, and here is his report:

Some months ago the *The R. N.-Y.* gave its opinion of the Electropoise, a device for which extravagant curative properties are claimed. The people who sell this contrivance promised, as proof of the value of their "Poise," to cure a person who has been an invalid for some years. That person tried the device carefully for two months according to the directions of the company's physician. He was to have tried it three months, but after two months' trial he was taken with a serious illness! His opinion of the Electropoise, after the two months' trial, is that, as a remedial agent, it exerts no effect whatever.

Books for Bee-Keepers and others.

Any of these books on which postage is not given will be forwarded by mail, postpaid, on receipt of price.

In buying books, as every thing else, we are liable to disappointment if we make a purchase without seeing the article. Admitting that the bookseller could read all the books he offers, as he has them for sale, it were hardly to be expected he would be the one to mention all the faults, as well as good things about a book. I very much desire that those who favor me with their patronage shall not be disappointed, and therefore I am going to try to prevent it by mentioning all the faults, so far as I can, that the purchaser may know what he is getting. In the following list, books that I approve I have marked with a *; those I especially approve, **; those that are not up to times, †; books that contain but little matter for the price, large type, and much space between the lines; †; foreign. ‡ The bee-books are all good.

BIBLES, HYMN-BOOKS, AND OTHER GOOD BOOKS.

As many of the bee-books are sent with other goods by freight or express, incurring no postage, we give prices separately. You will notice, that you can judge of the size of the books very well by the amount required for postage on each.

8	Bible, good print, neatly bound.....	20
10	Bunyan's Pilgrim's Progress**.....	30
20	Illustrated Pilgrim's Progress**.....	75

This is a large book of 425 pages and 175 illustrations, and would usually be called a \$2.00 book. A splendid book to present to children. Sold in gilt edge for 25c more.

6 First Steps for Little Feet. By the author of the Story of the Bible. A better book for young children can not be found in the whole round of literature, and at the same time there can hardly be found a more attractive book. Beautifully bound, and fully illustrated. Price 50 c. Two copies will be sold for 75 cents. Postage six cents each.

5	Harmony of the Gospels.....	35
3	John Ploughman's Talks and Pictures, by Rev. C. H. Spurgeon*.....	10

1	Gospel Hymns, consolidated Nos. 1, 2, 3, and 4, words only, cloth, 10 c; paper.....	05
2	Same, board covers.....	20

5	Same, words and music, small type, board covers.....	45
10	Same, words and music, board covers.....	75

3	New Testament in pretty flexible covers.....	05
5	New Testament, new version, paper covers.....	10

5	Robinson Crusoe, paper cover.....	10
4	Stepping Heavenward**.....	18

15	Story of the Bible**.....	1 00
----	---------------------------	------

A large book of 700 pages, and 274 illustrations. Will be read by almost every child.

5	The Christian's Secret of a Happy Life**....	25
8	Same in cloth binding.....	50

5	"The Life of Trust," by Geo. Muller**.....	1 25
1	Ten Nights in a Bar-Room, T. S. Arthur*..	05

5	Tobacco Manual**.....	45
---	-----------------------	----

This is a nice book that will be sure to be read, if left around where the boys get hold of it, and any boy that reads it will be pretty safe from the tobacco habit.

BOOKS ESPECIALLY FOR BEE-KEEPERS.

- 2 | Celery for Profit, by T. Greiner** 25
The first really full and complete book on celery culture, at a moderate price, that we have had. It is full of pictures, and the whole thing is made so plain that a schoolboy ought to be able to grow paying crops at once, without any assistance except from the book.
- 8 | Domestic Economy, by I. H. Mayer, M. D.** 60
This book ought to save at least the money it costs, each year, in every household. It was written by a doctor, and one who has made the matter of domestic economy a life study. The regular price of the book is \$1.00; but by taking a large lot of them we are enabled to make the price only 60 cts.
- 1 | Draining for Profit and Health, Warring. 1 50
- 10 | Fuller's Grape Culturist ** 1 40
This is, perhaps, the most systematic, comprehensive, and thorough work on grape culture now in print; in fact friend Fuller here tells us how, by easy steps, to make any grapevine come into the work, and make a pleasant, orderly appearance; and he makes it as attractive as a piece of fiction; and the best part of it is, that you get great crops of beautiful grapes during almost any kind of sea-son. We have tested the system, and know whereof we speak.
- 1 | Farming For Boys* 75
This is one of Joseph Harris' happiest productions, and it seems to be the only one that is so fascinating to any boy who has any sort of taste for gardening.
- 7 | Farm, Gardening, and Seed-Growing* 90
This is by Francis Brill, the veteran seed-grower, and is the only book on gardening that I am aware of that tells how market-gardeners and seed-growers raise and harvest their own seeds. It has 166 pages.
- 12 | Gardening for Pleasure, Henderson* 1 85
While "Gardening for Profit" is written with a view of making gardening PAY, it touches a good deal on the pleasure part; and Gardening for Pleasure takes up this matter of beautifying your homes and improving your grounds without the special point in view of making money out of it. I think most of you will need this if you get "Gardening for Profit." This work has 404 pages and 203 illustrations.
- 12 | Gardening for Profit 1 85
The latest revision of Peter Henderson's celebrated work. Nothing that has ever before been put in print has done so much toward making market-gardening a science and a fascinating industry. Peter Henderson stands at the head, without question, although we have many other books on these rural employments. If you can get but one book, let it be the above. It has 376 pages and 138 cuts.
- 1 | Gardening for Young and Old, Harris** 1 25
This is Joseph Harris' best and happiest effort. Although it goes over the same ground, occupied by Peter Henderson, it particularly emphasizes the youth and cultivation of the soil in preparing your ground; and this matter of adapting it to young people as well as old is brought out in a most happy vein. If your children have any sort of fancy for gardening it will pay you to make them a present of this book. It has 187 pages and 46 engravings.
- 10 | Garden and Farm Topics, Henderson** 75
- 5 | Gray's School and Field Book of Botany 1 80
- 5 | Gregory on Cabbages; paper* 25
- 5 | Gregory on Squashes; paper* 25
- 5 | Gregory on Onions; paper* 25
The above three books, by our friend Gregory, are all valuable. The books on squashes especially is good reading for almost anybody, whether they raise squashes or not. It strikes at the very foundation of success in almost any kind of business.
- 10 | Greenhouse Construction** 1 40
This book, by Prof. Taft, is just out, and is as full and complete in regard to the BUILDING of all glass structures as is the next book in regard to their management. Any one who builds even a small structure for plant-growing under glass will save the value of the book by reading it carefully.
- 15 | How to Make the Garden Pay** 1 35
By T. Greiner. This is a new book, just out, and it gives the most explicit and full directions for gardening under glass of any kind in the world. Those who are interested in hot-beds, cold-frames, cold-greenhouses, hot-houses or glass structures of any kind for the growth of plants, can not afford to be without the book.
- 1 | Handbook for Lumbermen 10
- 10 | Household Conveniences 1 40
- 2 | How to Propagate and Grow Fruit, Green* 15
- 2 | Injurious Insects, Cook 25
- 10 | Irrigation for the Farm, Garden, and Orchard, Stark 1 40
This book, Stark is well informed, is almost the only work on this matter that is attracting so much interest, especially recently. Using water from springs, brooks, or windmills, to take the place of rain, during our great droughts, is the great problem before us at the present day. The book has 374 pages and 142 cuts.
- 5 | Manures; How to Make and How to Use them; in paper covers 45
- 6 | The same in cloth covers 65
Covering the whole matter, and discussing every thing to be found on the farm, refuse from factories, mineral fertilizers from mines, etc. It is a complete summing-up of the whole matter. It is written by F. W. Semper.
- 7 | Market-gardening and Farm Notes, by Burnett Landreth 90
The Landreths are the pioneer seedsmen of America; and the book is worth fully as much as we might expect it to be. I think I received hints from it worth the price, before it had been in my hands fifteen minutes. It is exceedingly practical, and it is well to be on the safe side and what is BEING done, more than it discourses on theory.
- 3 | Maple Sugar and the Sugar-bush** 35
By Prof. A. J. Cook. This was written in the spring of 1887 at my request. As the author has, perhaps, one of the finest sugar-camps in the United States, as well as being an enthusiastic lover of all farm industries, he is better fitted, perhaps, to handle the subject than any other man. The book is written in Prof. Cook's happy style, combining wholesome moral lessons with the plainest and best method of managing to get the finest syrup and maple sugar, with the least possible expenditure of cash and labor. Everybody who makes sugar or molasses wants the sugar-book. It has 42 pages and 35 cuts.
- 1 | Our Farming, by T. B. Terry** \$2.00
In which he tells "how we have made a run-down farm bring both profit and pleasure."
This is a large book, 639 inches, 367 pages, quite fully illustrated. It is Terry's first large book; and while it touches on the topics treated in his smaller handbooks, it is sufficiently different so that no one will complain of repetition, even if he has read all of Terry's little books. I should call it the brightest and most practical book on farming before the world at the present day. The price is \$2.00 postpaid, or clubbing with GLEANINGS for 2.50. Those who are already subscribers to GLEANINGS may have it postpaid by sending us 1.50 more. We are so sure it will be worth many times its cost that we are not afraid to offer to take it back if any one feels he has not got his money worth after he has had it. It ordered by express or freight with other goods, 10c less.
- 3 | Onions for Profit ** 45
Fully up to the times, and includes both the old onion culture and the new method. The book is fully illustrated, and written with all the enthusiasm and interest that characterize its author, T. Greiner. Even if one is not particularly interested in the business, almost any person who picks up Greiner's books will like to read them through.
- 1 | Poultry for Pleasure and Profit** 10
- 11 | Practical Floriculture, Henderson* 1 35
- 10 | Profits in Poultry* 90
- 2 | Practical Turkey-raising 10
By Fanny F. Root. This is a 35-cent book which we offer for 10 cts.; postage, 2 cts.
- 4 | Peabody's Webster's Dictionary 10
Over 30,000 words and 250 illustrations.
- 2 | Rats: How to Rid Farms and Buildings of them, as well as other Pests of like Character 15
This little book ought to be worth dollars instead of the few cents it costs to any one who has ever been troubled with these pests, and who has not. It is written in such a happy vein that every member of the family will read it clear through, just about as soon as they get hold of it. It contains a complete summing up of the best information the world can furnish.
- 1 | Silk and the Silkworm 10
- 10 | Small-Fruit Culturist, Fuller 1 40
- 10 | Success in Market-Gardening* 90
This is a new book by a real, live, enterprising, successful market-gardener who lives in the suburbs of Boston, Mass. Friend Rawson has been one of the foremost to make irrigation a practical success, and he now irrigates his grounds by means of a windmill and steam-engine whenever a drought threatens to injure the crops. The book has 208 pages, and is nicely illustrated with 110 engravings.
- 1 | Ten Acres Enough 1 00
- 1 | Talks on Manures* 1 75
This book, by Joseph Harris, is, perhaps, the most comprehensive of the kind on the subject, and the whole matter is considered by an able writer. It contains 366 pages.
- 2 | The Carpenter's Steel Square and its Uses 15
- 10 | The New Agriculture; or, the Waters Led Captive 75
- 2 | Treatise on the Horse and his Diseases 10
- 5 | Tile Drainage, by W. I. Chamberlain 35
Fully illustrated, containing every thing of importance clear up to the present date.
The single chapter on digging ditches, with the illustrations given by Prof. Chamberlain, should alone make the book worth what it costs, to every one who has occasion to lay ten rods or more of tile. There is as much science in digging as in doing almost any thing else; and by following the plan directed in the book, one man will often do as much as two men without this knowledge. The book embraces every thing connected with the subject, and was written by the author while he was engaged in the work of digging the ditches and laying the tiles HIMSELF, for he has laid literally miles of tile on his own farm in Hudson, O.
- 3 | Tomato Culture 35
In three parts. Part first, by J. W. Day, of Crystal Springs, Miss., treats of tomato culture in the South, with some remarks by A. I. Root, adapting it to the North. Part second—By D. Cummins, of Connecticut, O., treats of tomato culture especially for canning-factories. Part third—By A. I. Root, treats of plant-growing for market, and high-pressure gardening in general. This little book is interesting because it is one of the first rural books to come from our friends in the South.
- 3 | Winter Care of Horses and Cattle 35
This is friend Terry's second book in regard to farm matters; but it is so intimately connected with his potato-book that it reads almost like a sequel to it. If you have only a horse or a cow, I don't think it will pay you to invest in the book. It has 44 pages and 4 cuts.
- 3 | Wood's Common Objects of the Microscope** 47
- 8 | What to Do and How to be Happy While Doing It, by A. I. Root 50

I shall be on my way to Atlanta about the time this reaches you, and shall be glad indeed to meet as many of the friends as possible.

SOLD OUT.

The Early Ohio and Early Puritan, both first and second sizes, are sold out, and the prospect is just now that we shall not be able to get any more to furnish at the low prices we have been offering them; also second sizes of all other potatoes are sold out except Lee's Favorite and Freeman.

ORDERING POTATOES NOW, TO BE SHIPPED WHEN YOU DIRECT IN THE SPRING.

We shall once more undertake to send out potatoes as we did last spring but we shall not risk starting them before the first of April, no matter how enticing the weather. You will need to order the potatoes now (say before Jan. 1st) to secure at the very low prices given in our potato circular mailed on application. You must either pay for them now, or make a sufficient payment on them to pay us for putting them up and furnishing cellar space for them till next April. Or we will ship them sooner providing you will stand all loss from freezing. In other words, they are to be shipped April 1 unless you direct otherwise. At the very low rates we have given, we shall very likely run out of many kinds before spring (Early Ohio and Early Puritan are already sold out); but if they are put up now, your name marked on them, "paid for," you make a sure thing of it. We guarantee them wintered safely without freezing, and with no more sprouting than can be prevented by an excellent cellar made on purpose, and opened and closed according to the weather, that they may be neither too hot nor too cold.

POLISHING MITTEN.

There are very few house-keepers who do not have a stove to black, and many take pride in making it shine. One of the best implements for this purpose is the polishing-mitten shown herewith. This is a woman's invention, and a good one too, as you might know. It consists of a mitten of oil-cloth, faced with sheep or lamb's skin tanned with the wool on. The mitten is accompanied by a dauber, also of wool on the hide. Those who have tried the mitten are loud in its praise. They are usually sold for 35 cts. postpaid. We can furnish them for 25 cts. sold, or with other goods, not postpaid, 20 cts. each, or \$1.80 per doz.; 3 doz., \$4.50. We will send one free, postpaid, for one new subscription to GLEANINGS at \$1.00.

ON TO ATLANTA.

Ask your ticket-agent for tickets to the Cotton States Exposition at Atlanta, Ga., via the Louisville & Nashville and Nashville, Chattanooga & St. Louis Railroads. This is the old soldiers' route during the late war, passing through Murfreesboro (Stone River battlefield), Tullahoma, Bridgeport, and for miles in full view and around the base of Lookout Mountain; also the famous Moccasin Bend to Chattanooga; thence over the Western & Atlantic Railroad to Atlanta. The schedules are as follows: The fast mail leaves Cincinnati at 11:30 A. M.; arrives at Louisville at 2:57 P. M.; Nashville, 8:58 P. M. Leaves St. Louis 7:52 A. M.; Evansville, 2:12 P. M.; Nashville, 9:10 P. M.; Chattanooga, 1 A. M. Arrives at Atlanta 6:50 A. M. The Cotton States Flyer leaves Cincinnati 7:30 P. M.; arrives at Louisville 11:14 P. M.; Nashville, 6:50 A. M. Leaves St. Louis at 7:35 P. M.; Evansville, 1:25 A. M. Due at Nashville 7:10 A. M.; Chattanooga, 11:50 A. M. Arrives at Atlanta 4:00 P. M. The Atlanta special leaves Cincinnati 5:30 P. M.; Louisville, 9:30 P. M.; Nashville, 2:40 A. M.; Chattanooga, 7:00 A. M. Arrives at Atlanta 11:25 A. M., and is a solid train from Cincinnati to Atlanta. All trains have elegant day coaches

and Pullman's finest sleeping-cars. HERMAN HOLMES, T. P. A., Medina, Ohio. Jackson Smith, D. P. A., Cincinnati, Ohio. C. P. Atmore, G. P. A., Louisville, Ky.

SOMETHING NEW IN COMB FOUNDATION.

We have in successful operation a new machine for sheeting beeswax, invented by E. B. Weed, formerly of Detroit, late of Ludlow, Ky. By means of the machine a decided advance is made in the manufacture of comb foundation. A much superior article is secured, at quite a reduction in cost of making. A patent has been applied for by the inventor, on the machine and its product. The wax is supplied to the machine in liquid form, and it comes from it in a continuous sheet of any desired thickness, and trimmed to width desired. It can be still further perfected so as to pass the sheet through the embossing-rollers of a foundation mill, and be trimmed to length as it comes out. Already, before the machine is quite out of the experimental stage, one man sheeting and another rolling, produced four hundred pounds of medium brood foundation in a day. Further particulars of the machine will be given later. We shall be pleased to mail samples of foundation to those interested. Foundation made by this process is more transparent, and less brittle when cool.

SEED BUSINESS FOR 1896.

With the much improved health I have been enjoying for the past few months, we are making better provisions for good seeds for 1896 than ever before, and many of them will be at greatly reduced prices. At present, prices have not been decided on all seeds, but enough so that we anticipate much pleasure in surprising our friends of past years with prices on many things lower than they have ever been since we have been in the business. We will try to give you a condensed list for Jan. 1. We are making arrangements, however, so that any orders sent in early will have the benefit of the reduced prices, even before they have come out.

GARDENING FOR DECEMBER.

In our locality, making garden for this month must be mostly confined to working under glass. As to how well this will pay, the only way I know of to find out is to make some practical tests. Take up some big heavy clumps of asparagus after the ground has been once well frozen; start them in a hotbed heated either by steam or manure, and see what you can get for asparagus-shoots along about Christmas and New Year's. If you have protection enough, do the same with kidney wax beans.

It is a good plan to start beets now, and they do not take very much heat, but it takes them a good while to grow. Sow the seed now, and you will have beets for market in January or February. They almost always bring big prices.

Wakefield cabbage and cauliflower usually bring good prices also, for growing under glass.

With the scarcity of celery all over the country, it is an excellent time now to work out some plan by which we can get nice celery under glass. We are trying it now. White Plume is the most promising.

Watercress always sells, and it is one of the easiest plants to grow under glass that we have ever tried. A package of seed costs only 5 cents, and directions for growing under glass go with each packet.

If you have got a nice warm greenhouse you can start cucumbers; but unless you have had experience you will probably fail.

Grand Rapids lettuce should now be pushing on in all stages of growth; and this probably leads all other growing vegetables as a winter crop. It always sells, and is one of the prettiest crops to manage I have ever had any experience with. Send to the Ohio Experiment Station, Wooster, Ohio, for their bulletin on growing lettuce by sub-irrigation.

You can start onion-plants now—a few of them—and the winter or Egyptian onion can be pushed now or any time later. But you must not keep it too warm. It is emphatically a cold weather plant.

Dig your parsnips—that is, enough to last while the ground is frozen—during any open spell.

The American Wonder peas are very easily grown under glass, providing you have the room to spare.

Peppers and tomatoes can be kept bearing all winter, if you have got a house warm enough, and take the precaution to save some plants before they are killed by frost.

Force rhubarb the same as asparagus; and the price you are offered for it should guide you in regard to when and how much you should start.

Radishes—especially the Scarlet Globe and early frame—require very little heat, and are exceedingly easy to manage. The same with spinach. It will stand more cold than any other plant, probably. In fact, we have nice spinach right outdoors, a great many times, nearly all winter.

If you want to propagate rare and valuable varieties of strawberries, you can easily keep them going all winter, and they can be pushed like spinach and winter onions in cold-frames, without any heat at all. All the expense will be in handling the glass, and giving them ventilation when there is very strong sunshine, and giving them a bath whenever we have a warm rain.

Last, but not least, you can have plants of the new Thoroughbred potato; and if you do not let the frost beat you out some time unexpectedly, you ought to have some new potatoes to plant by planting-time, next May or June.

KIND WORDS FROM OUR CUSTOMERS.

My! but your bee-supplies are most beautiful, and go together so very nicely! "MACK."
Bloomdale, O., Nov. 4.

THE MANUM SWARM-CATCHER INVALUABLE.

By the way, those swarm-catchers—the Manum—after one learns to use them are an invaluable thing. We change ours about on different lengths of poles to suit our swarms, having a pole with a hook on it to reach any of them for the purpose of shaking the limbs and closing the lid; then we raise the basket clear of the tree, and continue to shake the limb, and, presto! your bees are in the basket.

Fairfield, Ill., Nov. 19. T. C. STANLEY.

A KIND WORD FOR OUR BUSINESS HABITS, IF NOT FOR SOME OTHER THINGS.

Mr. A. I. Root:—While I do not approve of raw-meat or hot-water diet, or religious lectures, in business dealings your firm is away above par, and I shall always have a good word for your square dealing.
H. L. JONES.

[Thank you, friend J. Our readers will please notice the expression "raw meat" in the above. It seems strange where this could have come from. If anybody can direct my attention to any physician, ancient or modern, who prescribed raw meat to his patients, I shall be glad to know about it.]

THE PORTER BEE-ESCAPE THE BEST.

I want to say a word in favor of the Porter bee-escape. I have been using a cone escape, and thought they worked very well; but after trying a Porter I have no more use for a cone escape. The Porter clears every bee out of the super, in a very short time. I don't think the Porter-escape can be recommended too highly.
E. R. MAGOON.

Malone, N. Y.

THE CORNELL AND CRANE SMOKER.

The Cornell smoker came to hand last night. Thanks. I have examined it with a good fire in it, and think it is a good durable smoker, and very cheap. I think our men will prefer this to the Crane; but as for me, give me Crane every time. The last tin valve, I think, is all right—at least, it served me the whole season.
P. H. ELWOOD.

Starkville, N. Y., Oct. 31.

A KIND WORD INDEED FOR A. I. ROOT.

Dear Friend A. I. Root:—Whether you write about the entertainment and management of a hotel, about the processes of raising potatoes and of him who raises them, or be it about hanging the buzzards up on trees to dry, or the girl who gets the mail from a moving steamboat, or other of the multitude of life's vicissitudes, I have this to remark: That you possess in an eminent degree the ability to make every line and sentence highly interesting; and, above all, you seem to be able to make every phase of life and action a lesson of betterment and uplifting of human life and character. To me this seems to be the true model of journalism.

JOHN CADWALLADER.

North Madison, Ind., Oct. 19.

FOR THE CUBICAL HIVE.

I am more than pleased with GLEANINGS. It is really a marvel of cheapness and excellence. I can not imagine how you can furnish it at the price, let alone the quantity of extra matter it so often contains. I am much pleased with H. R. Boardman's article on the square-shaped hive (in GLEANINGS of April 15). I found that the long hive was the wrong hive for me, as I found the combs not occupied by the bees in winter got mildewy; but the combs in the top chambers on my square hives did not. I keep the top chambers on my hives all through the winter. It saves a lot of trouble. My broad top-frames keep the bees nice and comfortable in the brood-chamber. The excess of moisture and heat escapes via the end of the frames. The hives are always ready for any flow of honey that may be obtained in my locality, come when it may.

J. F. MUNDAY.

Woodville, N. S. Wales, Australia.

A KIND WORD IN VERY TRUTH, FROM AWAY DOWN IN TEXAS.

Mr. A. I. Root:—Ten or twelve years ago I sometimes worked for a neighbor who was then taking a journal published by you called GLEANINGS IN BEE CULTURE, I believe. I can well remember reading the interesting articles and letters about bees and their ways, etc. But what most interested me was your familiar "talks" that you gave on about the last pages. Although at the time I was only a rather small boy, yet I was interested and concerned about my soul's salvation, and I well remember how I used to read your words on religious subjects when no one was around, so that they would not see how interested I was in them. The impression left on my memory is a pleasant one. Now I want GLEANINGS, if you still publish it — not to find out how to be saved, because I gave my heart and life to Christ seven years ago, and he still has them in his keeping; but I do want GLEANINGS to read and find out how to work with bees properly. Then it will keep me posted on the latest improvements in hives and apary fixtures. I know I shall get a great deal of other information that will interest me. Well, here is a dollar for one year's subscription; and if it is more than that for a year, please let me know.
M. S. LUSBY.

Taylor, Texas.

AN ENCOURAGEMENT FOR WELL-DOING, IN THE SHAPE OF SOME EXCEEDINGLY KIND WORDS.

A. I. Root:—I am an officer of the navy, of many years standing, on the retired list. I have made a study of bees, and am conversant with a good deal of bee-literature. I have several times ordered material of your company for myself and others. At the first reading of your catalog I was struck with a peculiarity it seemed to exhibit, and on that account I have studied it carefully, and my first impression is confirmed. It is one of the few descriptive catalogs issued by manufacturers which seems to be thoroughly truthful, with no attempt to exaggerate or to mislead, or to overpraise any article made or sold by you. It does not hesitate to say that certain articles in the catalog are not recommended. It frequently advises the purchase of the lower-priced article. Throughout it cautions the beginner to avoid useless or unnecessary expense.

Of the articles I have received from you for myself and others, the catalog is faithfully descriptive. Therefore it is with pleasure that I write this to let you know the impression your business methods have made on one person at least, and to most heartily wish you a continuance of your deserved success.
EUGENE B. THOMAS.

Advantages of Bee-Escapes.

No sweat steals down the heated cheeks and aching back of the bee-keeper as the result of standing in the hot sun puffing, blowing, smoking, and brushing bees; no time is wasted in these disagreeable operations; and no stings received in resentment of such treatment; the honey is secured free from black or even the taint of smoke; the cappings are not injured by the gnawings of bees; and robbers stand no show whatever. If there are any broken burr-combs they are cleaned up by the bees *inside* the hive, before the honey is removed. **Leading Bee-keepers use the Porter Escape**, and say that without a trial it is impossible to realize the amount of vexatious, annoying, disagreeable work that it saves. The cost is only 20 cts. each, or \$2.25 per doz. As in the past, this escape is manufactured by the Porters, but THE A. I. Root Co. are now the exclusive selling agents for this country. Order of your dealer or of

Read what J. I. PARENT, of CHARLTON, N. Y., says—"We cut with one of your Combined Machines last winter 50 chaff hives with 7-inch cap, 100 honey-racks, 500 broad frames, 2,000 honey-boxes, and a great deal of other work. This winter we have doubled the amount of bee-hives, etc., to make, and we expect to do it all with this saw. It will do all you say it will."

Catalogue and Price List free. Address W. F. & JOHN BARNES, 545 Ruby St., Rockford, Ill.

When more convenient, orders for Barnes' Foot-Power Machinery may be sent to

In responding to this advertisement mention GLEANINGS

HONEY COLUMN.

CITY MARKETS.

PHILADELPHIA.—*Honey.*—Honey has advanced in this market, with prospect of still higher advance. Comb honey sells quickly, and pure white-clover extracted sells on sight. We quote comb, dark, 10@11; choice, 14@15; fancy, 16. Extracted, 5@6; New York white-clover, 6½; western white-clover, 10. Beeswax, 27.

Dec. 9. W. M. A. SELSER,
No. 10 Vine St., Philadelphia, Pa.

CHICAGO.—*Honey.*—We quote comb honey at the following prices: Fancy white 1-lb. sections, 14; No. 1 white, 13; amber, 12@12½; buckwheat, 10. Extracted, as to quality and style of package, 5@6½. Beeswax, 30.

Dec. 7. S. T. FISH & CO.,
189 South Water St., Chicago, Ill.

CLEVELAND.—*Honey.*—Our market is not quite so good as when we last quoted you on honey. We quote No. 1 white comb, in 1-lb. sections, 14@15; No. 2 white, 12½@13; buckwheat, 10. Water-white extracted, 7; amber, 6. Beeswax, 25.

Dec. 7. WILLIAMS BROS.,
80 & 82 Broadway, Cleveland, O.

ST. LOUIS.—*Honey.*—Market inactive; strained honey, in barrels, 3½@5; in cans, 4½@6. Comb, 10@12, according to quality. No dark wanted at any price. Prime beeswax, 28.

Dec. 9. D. G. TUTT GROCERY CO.,
St. Louis, Mo.

SPRINGFIELD.—*Honey.*—Honey is in only fair demand. White clover is selling at 16@17; buckwheat, 10@12.

Dec. 9. PERKINS & HATCH,
Springfield, Mass.

KANSAS CITY.—*Honey.*—The supply of extracted is not large; demand good for white. We quote No. 1 white 1-lb. comb, 13@14; No. 2, 12@13; No. 1 amber, 12@13; No. 2, 10@11; dark, 8@10; extracted, white, 6@6½; amber, 5@5½; Southern, dark, 4@4½. Beeswax, 22@25.

Dec. 9. C. C. CLEMONS & CO.,
Kansas City, Mo.

CHICAGO.—*Honey.*—White clover and linden in 1-lb. frame sell at 14@15, but other kinds of frames of white honey sell at 12@13; dark and amber grades, of which there is a liberal supply, 9@10. Extracted, dark grades, 4@5; amber, 4½@5; white, 5½@7; prices of different grades vary according to quality, fine flavor always being at a premium. Beeswax, 28@30, and sells upon arrival.

Dec. 11. R. A. BURNETT & CO.,
163 So. Water St., Chicago, Ill.

BOSTON.—*Honey.*—Comb honey is in good demand, but prices remain as before—13@15, according to quality. Extracted is quiet, with a full supply on hand; prices, 5@6.

Dec. 10. E. E. BLAKE & CO.,
Boston, Mass.

CINCINNATI.—*Honey.*—There is no life in the business. All kinds of honey are in good supply, with a rather slow demand for this time of the year. Best white comb honey sells at 12@15 in the jobbing way, while there is almost no demand for all off grades. Demand for extracted honey is fair at 4@7 on arrival. There is a good demand for beeswax at 22@27 for good to choice yellow.

Dec. 10. CHAS. F. MUTH & SON,
Cincinnati, O.

NEW YORK.—*Honey.*—We have a fairly good demand for white comb honey at 12@15, according to quality and style of package. While the market is well cleaned up of glassed sections and pasteboard cartons, unglassed is plentiful, having just received two more big carloads from California. Buckwheat comb is very dull, with large stocks on the market. We quote 9@10; but, to effect sales on quantity lots, it is necessary to shade quotations. Considering the limited outlet and large supply, we would not encourage shipping of buckwheat honey, as we could not render returns in reasonable time. The market on extracted is quiet, at unchanged prices. No demand as yet for extracted buckwheat. Beeswax is in good demand, and sells at 29@31.

Dec. 9. HILDRETH BROS. & SEGELKEN,
28 & 30 West Broadway, New York.

MINNEAPOLIS.—*Honey.*—Since last writing you there has been little or no change in the honey market here. A carload of California comb honey came in and is selling at 14@15. There is a fair supply of water-white extracted which we quote at 6½. White amber, 6; yellow amber, 5@5½; all in 60-lb. tins. Beeswax, 28@35.

S. H. HALL & CO.,
Minneapolis, Minn.

BUFFALO.—*Honey.*—Honey market is very quiet, and very little doing. Fancy is in light supply, and firm at 16; No. 2, 12@14; buckwheat is dull at 8@10. Extracted dull. Beeswax, 25@28.

Dec. 7. BATTERSON & CO.,
Buffalo, N. Y.

KANSAS CITY.—*Honey.*—The demand for comb and extracted is good. One-lb white, 13½; amber, 12; dark, 10. Extracted, white, 6½@7; amber, 5@5½; dark, 4½. Beeswax, 22@25.

Dec. 11. HAMBLIN & BEARSS,
Kansas City, Mo.

ALBANY.—*Honey.*—There is a large stock of buckwheat comb honey on our market, and it is selling very slowly at 9@10 for 1-lb. combs, and 8@9 for 2-lb. Clover continues scarce, and No. 1 sells at 14@15. There is but little demand for extracted yet. We look for an improvement after Jan. 1st.

Dec. 9. CHAS. MCCULLOCH & CO.,
Albany, N. Y.

DETROIT.—*Honey.*—Best white comb honey is selling at 14@15, with fair demand; dark grades, 12@13; extracted, 6@7. Beeswax, 26@27.

Dec. 9. M. H. HUNT,
Bell Branch, Mich.

FOR SALE.—20 boxes extracted honey, two 60-lb. cans in each box. Price 6½¢ per lb.

JNO. A. THORNTON, Lima, Ill.

FOR SALE.—11,000 lbs. basswood honey, equal to the 500 lbs. I had in our State exhibit at the World's Fair. Price, 8 1-gallon square cans in a case, \$6.00; 1½ 1-gallon cans in a case, \$6.30.

F. A. BEALS, Salix, Ia.

Extracted honey in barrels at 6½ cts., or in 60-lb. cans at 7c.

CHAS. DADANT & SON,
Hamilton, Hancock Co., Ill.

WANTED.—To sell quantity lots of fancy comb honey. Also to sell water-white extracted honey in 60-lb. cans.

B. WALKER, Evart, Mich.

ALFALFA HONEY, very white, thick, and rich. Two 60-lb. cans at 7c. Same, partly from clover (tinted), 6c. Samples, 8c.

OLIVER FOSTER, Las Animas, Col.

ALFALFA IN ARIZONA.—We will sell you alfalfa honey F. O. B. Phoenix at 4½c in 1000-lb. lots or more. Less than 1000 lbs. at 5c in five-gallon cans. Car lots a specialty.

J. P. IVY,
Secretary Bee-keepers' Association,
Phoenix, Maricopa Co., Arizona.

CONVENTION NOTICE.

The Wisconsin State Bee-keepers' Society will meet Feb. 6, 7, 1896, in the Capitol building, Madison. Program later.

N. E. FRANCE, Sec., Platteville, Wis.

The Southwest Texas Bee-keepers' Association meets at Wharton, Texas, at the apary of W. O. Victor, Dec. 26 and 27. Everybody is invited, and bee-keepers especially. Come, and let's have the largest meeting ever had. Low rates on all railroads. Remember the date.

J. O. GRIMSLEY, Sec., Beeville, Texas.

Those intending to attend the special meeting of the Illinois State Bee-keepers' Association, in Chicago, Jan. 9 and 10, will please notice that railroad rates will be on the certificate plan—certificates to be taken at place of purchasing ticket, and issued at Chicago, before returning, by the agent of the Cycle Exhibition Co., and vised by the joint agent of the railway lines. Tickets going may be obtained at any time between Jan. 1st and 11th, and return at any time between Jan. 4th and 15th.

JAS. A. STONE, Sec.

Honey for Sale!

2500 lbs. of A No. 1 amber fall honey for sale, in 60-lb. cans, 2 cans in a case; price, single can, 8c per lb.; 2 or more cans, 7c. Send 2 cts. for sample. Address E. T. Flanagan, Box 783, Belleville, Ill.

EARLY-ORDER DISCOUNT.

Only two weeks of this year remain in which to take advantage of the December four-per-cent early-order discount. Look over your stock of supplies and send us your order for such things as you are in need of for next season. We are in position to give your orders our very best attention.

HONEY.

We are still prepared to supply choice comb and extracted honey at very low prices. Shall be pleased to hear from those interested, stating quantity they can use. We have choice alfalfa comb in 1-lb. sections, 24-lb. cases, at 15c per lb., in lots of 4 cases or over. The same honey in No. 2 or unfinished sections, 3c per lb. less. Extracted California and alfalfa, in 60-lb. cans, at 7c in lots of 2 cases or over.

BEESWAX WANTED.

The wax market still continues firm, with a decided upward tendency in price. Those who have it for sale can now realize a good price. If our advertised price is not equal to other offers you have, write us, stating quantity you have to offer, and the price you are offered. We need wax, and can afford to pay as good a price as anybody. Let us hear from you.

YOUR OWN WAX WORKED INTO FOUNDATION FOR YOU.

With our new process of sheeting wax we are much better able to work up individual lots of wax into foundation. There are some who have a decided preference for having their own wax, and go so far as to invest in a foundation-mill in order that they may have foundation made of their own wax. We are prepared to receive your wax, and work it into foundation of our superior new process at the following rates, you paying charges both ways. For not less than 25 lbs.:

Heavy and medium brood foundation, 12c per lb.	
Light brood " " " " " "	15c " "
Thin surplus " " " " " "	20c " "
Extra thin surplus " " " " " "	25c " "
Lots of 200 lbs. or more at special prices on application.	

KIND WORDS FROM OUR CUSTOMERS.

I can't see how I could get along in the "bee biz" without your valuable semi-monthly.
Albuquerque, N. M., Dec. 3. J. R. McCOWAN.

The queen came O K; and to say I was pleased does not express it; therefore please accept thanks, and I have just been testing the Porter bee-escape. They are just what every bee-keeper should have.
Starkville, N. Y. A. H. SMITH.

FIVE QUEENS ALIVE TO AUSTRALIA.

The bees arrived all right; 5 out of the 9 were alive, and as lively as if they had just come out of the hive. The other 4 succumbed on the passage. I am well satisfied, as I did not expect otherwise.
Auckland, N. Z. FREDERICK RICHARDSON.

THREE QUEENS ALIVE TO AUSTRALIA.

I am pleased to be able to report that 3 out of the 5 queens arrived alive by the last mail. The two in envelopes were the ones dead, I think, but of this I can not be quite sure, as I was not present when they were opened, and my son was not aware I was desirous of knowing whether an envelope was an improvement on the method of packing. A close-fitting envelope, such as you used, is not what is wanted, but a large one similar to what is used by solicitors for deeds, etc. T. G. BRICKTELL.
Dunedin, N. Z., Oct. 29.

MORE ABOUT RAW BEEF.

In reply to GLEANINGS I would say that Dr. J. W. Sykes, Penn Ave., Pittsburg, in 1874, put my brother

on raw beef, to be scraped as lint is scraped from cloth. It was not used exclusively, but it built him up, and made blood the quickest of any thing I ever saw. I use it with a little vinegar and black pepper on it, because I like it. G. W. MARTIN.
Saltsburg, Pa., Dec. 5.

HOW TO KEEP SEED POTATOES FROM SPROUTING DURING THE WINTER.

Friend Root:—The following may be of use to you: Last winter we saved more Freeman potatoes than we afterward decided to plant, just such as we sent you. Some 40 bushels of these, as I remember, were sold to The Robertson Celery and Produce Farms, Kearney, Neb. The manager wrote me then that he could get seed cheaper, but wished to try ours. Nov. 16 he wrote me that the Freeman seed got from us did finely. Tried side by side with other seed of the same variety, purchased elsewhere, the plants from our seed were so strong and healthy that they seemed like a different and stronger-growing variety. This is exactly what we thought our seed would do when we sent it out. We haven't grown potatoes all these years for nothing. Kindly shovel over with a wooden shovel the New Queen and Freeman potatoes you have once a week, when it becomes necessary, beginning before any sprouts start to speak of, and keep them cold, and I think they will give as good, or better, results as the seed sent to Kearney. T. B. TERRY.
Hudson, O., Dec. 7.

Mr. Root:—I bought of Mr. Craig last spring four quarts of his Craig Seedling potatoes; planted one eye in the hill. They froze once after they were up, then there were twenty hills missing. They kept green till the frost killed them. I dug 345 lbs. of nice potatoes, or 5 3/4 bushels, allowing 60 lbs. to the bushel. I think them very good cooking potatoes.
Vienna, N. Y., Nov. 9. W. P. ABEL.

Wants and Exchange Department.

Notices will be inserted under this head at one-half our usual rate. Advertisements intended for this department must not exceed five lines, and you must say you want your advt in this department, or we will not be responsible for errors. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale, can not be inserted under this head. For such our regular rates of 20 c. a line will be charged and they will be put with the regular advertisements. We can not be responsible for dissatisfaction arising from these "swaps."

WANTED.—To exchange foundation-mills and honey-extractors for honey or wax.
I. J. STRINGHAM, 105 Park Place, New York.

WANTED.—To exchange 200 colonies of bees for anything useful on plantation.
ANTHONY OPP, Helena, Ark.

WANTED.—To exchange safety bicycles, Barnes No. 4 1/2 lathe for metal work, Odell type-writer, for honey, beeswax, or gasoline or kerosene engine.
J. A. GREEN, Ottawa, Ill.

WANTED.—To exchange Japanese buckwheat for bee-keepers' supplies or fdn. mill.
PHILIP RATH, Oraville, Jackson Co., Ill.

WANTED.—To exchange peach-trees, and Abondance, Burbank, and Satsuma plum-trees for Italian bees.
JOHN CADWALLADER,
North Madison, Ind.

WANTED.—A young man with small family to take charge of a fruit-farm. German preferred. Will furnish good house and give good wages.
Write to J. B. MURRAY, Ada, Ohio.

WANTED.—To exchange 26-in. planer and matcher and scroll-saw (for power) for wood-working machinery or cash. GEO. RALL, Galesville, Wis.

WANTED.—To exchange chaff hives in flat, and tin-type outfit for bicycle.
WM. DE WORTH, Bordentown, N. J.

YOU "CAN'T AFFORD

very much. Send me a few cents in stamps and I'll send you a bundle of back numbers (the more stamps sent the bigger will be the bundle), and if, after looking them over, you can suggest any improvement, any plan whereby the REVIEW can be made better, that I think well enough to adopt, the REVIEW will be sent you free for 1896.

W. Z. Hutchinson, Flint, Mich.

He offers Italian Queens—good, old-style honey-queens—untested, first order, to any address, at 50c each. Also bees in any quantity; 450 colonies to draw from. **Root's goods constantly in stock.** Prices to suit the times. Buy near home, and save freight.

Vol. XXIII.

DEC. 15, 1895.

No. 24.

STRAY STRAWS

FROM DR. C. C. MILLER.

THE PROPOSED CONSTITUTION, as given on p. 892, has the approbation of the editor. Very decidedly it hasn't mine, at least on some points. [Well, on what points?—Ed.]

DOUBLING UP colonies, as mentioned by friend Aikin, page 890, seems to be just the thing, and I don't know but it is; but so far, when I've tried it, it didn't pan out well.

S. E. MILLER wants to know, p. 893, why I'd nail numbers to hives instead of carrying them in my head. Well, my head isn't large, and I've better use for what little room there is there.

WHEN SNOW COMES a foot deep in November, as it did this year, there's lot's of comfort in thinking, "How glad I am I got the bees in before this cold weather!" And the deeper the snow the deeper your comfort.

STERN WINTER now has come;
No more the joyful home
Within the busy hive is heard;
Silent, silent, dome.

The bees are all now home,
Till spring to life again has steard.

CRIMSON CLOVER. Michigan Experiment Station Bulletin says: "In England, where this clover is grown with some difficulty, it is said to winter-kill if sown on newly plowed land, but to pass the winter uninjured if merely harrowed in on stubble."

A SLANDER on A. I. Root. *New convert to the beef and hot-water treatment.* "Mr. Root wants me to drink hot water an hour and a half before every meal, and here I've been drinking for the last forty minutes; but I'll be jiggered if I can swallow another drop."

DID YOU EVER NOTICE that bees are unusually quiet directly after a windy time? I don't mean during the wind, for then you can't hear them for the noise of the wind; but I mean in the following calm. I suppose it's because the

wind has thoroughly ventilated the cellar, and the bees are not suffering for fresh air.

THE EDITOR fudges at the idea of my leaving one colony of bees outdoors, and asks, "Why don't you try more?" Because the last time I tried it I tried ten and lost them all. Fudge! yourself. [So I will fudge! so, there. I don't believe you had 'em packed right.—Ed.]

A CONFECTIONER of Neudorf, says *Le Bulletin d'Alsace-Lorraine*, found it convenient to scald the bees that entered his premises. The bee-keepers sued, and the authorities obliged him to screen his premises against the bees, and to keep his empty casks and cans out of their reach.

SOME BITTER EXPERIENCE resulted from putting a second story on top, as described by F. L. Murray, p. 890. A cold spell came, and the bees couldn't keep both stories warm. Since then I put the second story of empty combs *under*, and then it can make the bees no colder. the rest of his practice seems good.

THAT MAP showing the region of small and the region of large hives will be a rather complicated affair when such men as friend Crane want different-sized hives for apiaries not ten miles apart. [That map, I am afraid, will never materialize; for bee-keepers don't respond to the call for information.—Ed.]

I HAVE SAMPLES of the new foundation mentioned on p. 912. It is fine and beautifully clear, the only question being whether the bees will like it more or less thereof. How is that? [That is to be determined; but from experiments made last season for Mr. Weed, the inventor of the process, it seemed that the bees took to it more readily.—Ed.]

A. I. Root thinks, p. 910, that his flat-pea roots have not gone the great distance claimed. Perhaps not; but are you sure, friend Root, that you followed the roots to the end? This week I saw a gooseberry-plant that had been very carefully dug. It was a cutting set in the open ground last fall, so it was one season's growth. With ordinary digging the roots might have been 8 or 10 inches long. As it was, they measured 34 inches! [The roots of the

flat pea do go down a great way, doctor; in fact, I have never been able to ascertain how far. All I meant to complain of was that the plants did not stand drouth, at least not on our clay soil, as we had been led to suppose they would. They kept alive, it is true, but they got awful yellow and sickly-looking.—A. I. R.]

IT'S A CLEAR CASE, that the general good demands that bees be kept out of candy-factories, cider-mills, and such places, and it's nearly as clear that the owners of such places should fasten them out rather than to have bee-keepers fasten them in, and there's no reason why bee-keepers of this country should not at once be up with the French in demanding proper laws on the subject.

IN ONE RESPECT, bee-escapes to be left on over night will not be as good in the future as they are now; for when they have been used longer it will become known to some of the light-fingered gentry, and it will be very convenient to come in the night and carry off a few supers. [It will be seldom, I think, that the "light-fingered gentry" will know enough about bees or escapes, even when these articles come into more general use, to know when they are on, and some escapes don't show from the outside. But suppose these chaps do come to know the purpose of the escape: that knowledge would also imply a knowledge of how to get the honey off, escapes or no escapes.—Ed.]

WHEN SOME ONE DIES there's more commotion about his death than about his birth. Just the other way with bee-journals. There's a big hullabaloo at their birth, but not a word said about their final illness, and generally you never hear they're gone till they've been dead a long time. Been several deaths lately. Died very peacefully. [Let's see. Four have died in almost as many months. The publisher of one of them specially requested that I forbear mentioning its demise, perhaps because he couldn't bear to see its obituary.—Ed.]

CAN BEES KEEP gently on the move all winter long in the hive, and remain healthy? Or if at the right temperature, do they lie motionless and entirely quiet most of the time, awaking and moving about by spells? If the latter, how far apart are the periods of activity? Or how does a colony wintered in best condition spend its time in winter, any way? If those who have bees in cellar would take notes this winter, and report, we might have something settled by spring. Friend Taylor could help out. [Mr. R. McKnight has something on this subject in this issue.—Ed.]

SHAMROCK, the national emblem of Ireland, is nothing more nor less than our much-valued white clover. It is worn in honor of St. Patrick, who is said to have plucked a leaf of this plant to represent the Trinity. The botanical name is *Trifolium repens*. It is also called Dutch clover, white trefoil, white meadow trefoil,

creeping trifolium, creeping clover, stone clover, honeysuckle-grass, honeysuckle-clover, and, in Germany, sheep-clover, field, bee, and little clover. The French name is triplet, trefle blanche, or blanc; Spanish, trefol blanco; German, weisser Klee; Italian, trifoglio.

SAY, MR. EDITOR, there's no charge against the Atchleys in that Straw about the series copied from *American Bee Journal*. I think the *Southland Queen* mentioned that it was so copied; but I thought you hadn't recognized it in its new setting. [Why didn't you say the *Queen* acknowledged the source of the lessons? Yes, I find that the Atchleys did give credit to the *American Bee Journal* in their September issue, but not in the October number to which I referred. Now, doctor, as you helped me "put my foot in it," will you help me pull it out? I hereby tender my apology to *The Queen* for not being better acquainted with its columns.—Ed.]

BOTTOM BARS. "If wider than $\frac{3}{4}$ inch," says the editor, p. 888, "there is almost sure to be a useless bee-space between the bottom edge of the comb and the bar." What proof have you, Mr. Editor, that such space will be any worse with $1\frac{1}{8}$ inches than with $\frac{3}{4}$ inch? [Only observation. I have noticed that, the narrower the bar, the more inclined the bees are to build down to and fasten to it. We have a good many bars $\frac{3}{4}$ inch wide, with the combs attached to them. We had a few such comb attachments when the bars were $\frac{7}{8}$ inch wide. We at one time had a few frames with bottom-bars one inch wide. I think there were no combs attached to these. We never, that I remember, had bottom-bars $1\frac{1}{8}$ inches wide; but the foregoing would indicate that they would be worse still.—Ed.]

LARGE VS. SMALL HIVES.

Stop the hive discussion! oh, stop it! I am a ruined man — entirely ruined! or I have made my fortune! After the discussion had gone on some time I saw clearly that I was using too large a hive. The majority in GLEANINGS said so, and the majority must be right. So I went to work and sawed off 4 inches

from the back end of my hives. Then I settled down and was contented. But I watched

GLEANINGS and the hive discussion with a keen interest.

What is this—this thunder of the warhorse, rushing on to the battle, eager for the cannon's roar and the rattle of musketry—the riders shouting victory! as they hurl themselves on the foe? It is an overwhelming victory for the *larger-hive* men.

Then I was in a bad fix. I could not lengthen out my hives again, but I could do the next best thing—I could give the bees more room in front, so I added 4 feet to my alighting-board.

The discussion went on—always went on—till I made out a large majority for *smaller hives*. What could I do? There was no other way than to cut off 4 inches more.

After this came a wild war-whoop from the West that bore down all before it, and scored a complete victory for the *larger-hive* men. I added 4 feet more to my alighting-board.

Then there came a wail—a plaintive and beseeching wail of sorrow—from the far East—a heart-rending plea for *smaller hives*. I could not resist it, and I cut off 4 inches more.

Then I was called away from home, and could not consult GLEANINGS till I returned. When I did get hold of it I read the discussion eagerly, and there was a large majority for *smaller hives*. So I cut off 3 inches more. After I had completed the work I found I had got hold of the wrong number—not the last one. The latest GLEANINGS gave a big majority for *larger hives*. I added 4 feet to my alighting-board.

SKYLARK'S HIVE.

Then there came to my heart, voices—voices from the far-away South and the far West—voices laden with the perfume of the orange and the nectarine—sweet, tender, gentle voices, pleading for a *larger hive*. I immediately added 4 feet to my alighting-board!

Then for a good many issues the vote wavered, balanced, was a tie, or neither party had a decided majority. Then came another great majority for *smaller hives*, and of course I had

to saw off 2 inches more. This leaves my hive just 2 inches long. Now, if this discussion continues with large majorities for *smaller* hives I shall have to saw off the front door and let the bees camp on the alighting-board. Here is a picture of my hive *now*.

Do you believe this hive will be a success, or am I a ruined man?

FRIEND JONES APPEARS.

I was just about to mail you this splendid experiment of mine when friend Jones came over to see me.

"Hello, Skylark! what does all this mean—the sun-extractor full of brood, young larvæ, eggs, and honey—this large amount of wax, and this great pile of kindling-wood?"

"Well, Jones, I have just completed a great work. You know that GLEANINGS has, for the last six months, had a hive discussion on hand;" and then I told him the whole story.

"I never heard or read of the like of this—you are justly called the 'idiotic giant.'"

"Now, Jones, you know that refers only to the large amount of undeveloped intellect baled and stored away in my mind."

"Yes, truly it is baled, and baled so tightly that it has as much sense in it as there is in a bale of hay. Do you see that plank there? Why didn't you get a dozen or two of these, and saw them into blocks? You could have put in a block, and then a bale of your undeveloped intellect, and then another block and bale, and thus made the hive as small as you pleased. The blocks and bales would act equally well as dummies."

This was so unkind that I could do nothing else than burst into tears.

"Now look here, Skylark, be something of a man. You have lost \$600, but you can get back there. Buy a hundred new hives. Take that thing you call a hive, and cut some off the bottom. Set it, bees and all, in the side of the new hive, and fill up with frames. Put on the honey-boards and top boxes, and feed \$200 worth of sugar. You may be able to build them up by the next honey-harvest; but if you don't do this you are a ruined man."

Now, I don't care what is said against my moral character. The people know I am not a bad man, and won't believe it; but when any one tells them I am a fool, they *will* believe that, for they have often thought so themselves.

ANOTHER WOULD-BE SUICIDE.

The plea for old oil-cans, by friend Butler, on p. 769, is certainly a great advance in apiculture—backward. When you can teach a man to save a dollar and lose three, you are certainly doing him a great service—likewise backward. He pays 20 cents for his cans and 25 for his case—45 cents; a new case and cans costs 80 cents; so he is ahead 35. Now, when he goes to sell, the trouble comes in. No dealer will give as much

for honey put up in oil-cans by half or three-quarters of a cent as he would in honey-cans; so he saves 35 and loses from 60 to 90 cents. Besides, if he attempts to put them up in old oil-boxes, which he can also get cheap, he will lose 6 lbs. of honey in the tare, for they and the cans weigh only 12 lbs.; but the dealer exacts the full tare. An old oil-can is a good deal like a man of bad character—it always smells of it. No honey-producer here, of any note, uses oil-cans for honey. They would not use them if delivered free at the apiary! No, let us be honest; let us send out nothing but pure stock, with every package new, neat, and clean. It is the only way to success in our calling.

CALIFORNIA STATE CONVENTION ECHOES.

Nov. 18 and 19, Prof. Cook presided over a gathering of about sixty earnest and go-ahead bee-keepers in the Chamber of Commerce, Los Angeles.

The forming of some kind of coöperative association, either independent or in conjunction with the fruit-men, was the topic that had precedence at all times over all other topics.

It was figured out during the convention, that extracted honey, on an average, for a series of years, costs $4\frac{1}{2}$ cts. to produce, and that the average crop is 65 lbs. As the present price of honey is from 3 to 4 cts., it is evident the bee-keeper is getting next to nothing for his labor.

The present slipshod method of marketing honey is largely to blame for the low prices.

The citrus fruit-men are so well organized that they can estimate several months in advance the probable number of car-loads of fruit there will be to ship. The honey-producer has never yet been able to tell how much honey has been produced even months after its disposal.

With these and many other facts before them, the association appointed a committee of five to formulate some plans for coöperation in the sale of honey. The committee deliberated several hours, and they reported in favor of independent action, and upon lines similar to the Fruit Exchange, and recommended the forming of a

CALIFORNIA HONEY EXCHANGE.

Their report was unanimously adopted, and the committee continued. Their work is an arduous one, and may take many months in accomplishment; but the staying qualities of the committee lead bee-keepers to hope for success. Geo. W. Brodbeck, W. T. Richardson, R. Dunn, Dr. Millard, R. Touchton, original committee, to which were added Prof. Cook and J. H. Martin.

Abbott Kinney gave an interesting talk upon eucalyptus. There are 150 varieties. The

Robusta, Fisatola, and Eugensitas, are especially rich in the secretion of nectar, and bloom in that portion of the year, from November to March, when bees get but little honey from other sources. California bee-keepers were recommended to plant those species that produce the most honey.

The pepper-tree is not considered a good honey-producer. Where enough of it has been secured, the testimony seemed to class it as dark, and with a peppery flavor. Mr. Wilkin, who has had long experience, and ought to know, says that this peppery flavor comes from a weed known as "blue curl."

Alfalfa is drawing more and more attention as a honey-producer, and in the central portions of the State it is the leading source from which the honey is obtained. It is destined to become the leading honey-plant in many other portions of the State.

Mr. J. S. Harbison sent his compliments to the assembled bee-keepers in the form of an interesting and instructive letter. The following is a sample nugget: "It is safe to say that no product of soil or water, whether fish, flesh, or fowl, or that of fruits in all the varied forms in which they are marketed, is sold at so low a price, relative to excellence, as is that of our highest grades of California honey." "Oursage honey has no superior in any country, and should sell for fully 50 per cent more than it has for the past few years."

Diseases of bees were discussed. The new bee-disease seems to be more prevalent near the coast than in the interior. Henry Otto, in a communication, claimed to have cured foul brood with the new drug, creoline.

Resolutions of respect to the memory of the late L. L. Langstroth, and sympathy to his family, were passed. Also, that the California bee-keepers would coöperate with the bee-keepers of the world in the erection of a suitable monument to the memory of the father of American apiculture.

Nearly all of the old officers were re-elected, and the meeting adjourned.

Will California bee-keepers, who do not receive notices of our meetings, send their address to the secretary with the address of their neighboring bee-keepers? The secretary wishes to keep every bee-keeper on this coast posted in relation to the *California Honey Exchange*.

Jacob Alpaugh, of Ontario, Canada, spent last winter in California, and was so well pleased with our State and our association that he is here now with his whole family, and again attended our meeting. In spite of what John Dryden said at the national gathering, he is bound to annex himself and belongings to Uncle Sam. Plenty of room here, gentlemen; flowers the whole year round, and no frozen toes.

JOHN H. MARTIN, Sec.

Bloomington, Cal., Nov. 20.

LANGSTROTH MEMORIAL.

Langstroth as a Man, Minister of the Gospel, College Professor, Editor, Bee-keeper, and Inventor.

Interesting Reminiscences from His Life History.

Tributes of Praise to His Memory.

A Few Factors that have made American Apiculture what it is.

CONTRIBUTIONS FROM THE EDITOR OF THE BRITISH BEE JOURNAL; FROM THE EDITOR OF THE BIENENZEITUNG (GERMAN); FROM THE EDITOR OF THE REVUE INTERNATIONALE D'APICULTURE (SWISS); FROM THE FORMER EDITORS OF THE AMERICAN BEE JOURNAL; FROM HIS FORMER PASTOR; FROM CONTEMPORARIES OF HIS EARLY BEE-KEEPING EXPERIENCES.

REV. L. L. LANGSTROTH.

Palmas qui mernit ferat.

THE EVOLUTION OF MOVABLE FRAMES; LANGSTROTH'S GREAT STEP FORWARD.

By Thos. Wm. Cowan, Editor of the British Bee Journal.

It was certainly with profound sorrow that I learned of the sudden death of Mr. Langstroth, and I am sure this sorrow must be shared by a large number of bee-keepers who not only knew him personally, but also through personal correspondence with him. And yet these are few compared to the still greater number who must know him through his work, and who will not only have to mourn his loss as a benefactor, but also as the "father of American apiculture."

Langstroth's name is closely connected with his invention, and this has certainly placed bee-keeping upon an entirely different footing to what it occupied before the advent of the frame hive. There has been a great deal of controversy as to who was the original inventor of the frame principle. It was not till 1851 that Langstroth invented his hive, and frames had already been in use some years previously. They were, however, not of any practical utility, for the hives containing them were complicated, or so exceedingly expensive that they could be looked upon only as luxuries for rich amateurs rather than hives to be used by bee-keepers for business purposes.

Putting Huber's leaf hive—which was undoubtedly the first on the principle of movable frames—and similar hives, on one side as not being suited for general bee-keepers, we come to the hive of Major Munn, who first employed hanging frames in 1834. There was no lateral movement to these, and for examination they were drawn up into a glass case. Nor were they interchangeable, as are the frames

of the present day. The cost of such a hive was from \$35 to \$40, and consequently they could be used only by the wealthy amateur.

In 1841 Prokopowich invented his frame hive, which was a rather remarkable one, and of special interest just now, as the principle he advocated has recently been revived. His hive consisted of two body boxes having frames with wide bars, openings being cut out to allow the bees to pass from one box to another. The super was fitted with similar, but shallow frames. There was a small space admitting of slight lateral movement of the frames, so that they could be drawn out without crushing bees. But the principal feature of this hive consisted in its being constructed for inversion, or being turned upside down. Bee-keepers of the present day will have no difficulty in recognizing this principle, and will, perhaps, note to whom they should give the credit of the invention. Put to practical use, this hive did not answer the expectations of its inventor, and the bee-keeper found that, in strong colonies, it was impossible to remove the frames without crushing bees. Moreover, the frames became so propolized and firmly fixed together that it required a strong wrench to pull them asunder.

In 1843 Debeauvoys introduced his frame hive. This was an improvement upon the others, but it did not come up to what was required. The frames were awkward in shape, and it was difficult to insert them into, and remove them from the hive. They could be taken out only consecutively, like the frames of the German hives of the present day. The hive also, being too complicated, was of no use practically.

It was not till 1851 that Langstroth invented his frame hive, which, from its simplicity, cheapness, and practical adaptability to the purposes required, has conferred a lasting boon on bee-keeping. There are no doubt some who think other methods are quite as good; but a very large and daily increasing number of bee-keepers on this continent of Europe recognize that the principle introduced by Langstroth—and first published by him in 1852 in his book on the honey-bee—is the correct one. The opening of the hive at the top, the perfect interchangeability of the movable combs, and the lateral movement of the frames, have given the bee-keeper the most perfect control over his bees, and have more than justified Langstroth's expectations when he wrote the note in his diary in 1851, that "The use of these frames will, I am persuaded, give a new impetus to the easy and profitable management of bees."

We here in Europe have for a long time held Langstroth in the highest esteem; have appreciated his invention, and only a few years ago we—British bee-keepers—did ourselves the pleasure of electing him an honorary member of the British Bee-keepers' Association, as a

recognition for the services which he had rendered to apiculture.

There are not many bee-keepers of the present day who can look back 40 years, or who know how Mr. Langstroth was treated, even by those who were quick to perceive the advantages to be derived from his invention; or how they pilfered his best ideas, and even patented them, and how he was defrauded of his just dues. Nor do they know that these infringements of his rights led to costly litigation which swallowed up all his well-merited gains. As one of your own writers (Prof. Cook) has written in GLEANINGS: "This whole matter is the dark page in American bee-keeping history, and we gladly pass it by without further comment."

Langstroth was not in flourishing circumstances; and although a fund was raised to assist him in his old age, the sum realized fell very far short of what it should have done, more especially when we consider what benefit has been derived from his invention. Although bee-keeping here is not carried on as a business—such as it is in America—it was a real pleasure to British bee-keepers to be allowed to add their mite toward the fund raised. This distinguished man would no doubt have suffered less had he been in affluent circumstances, and able to take change of air at the approach of his periodical attacks of illness; but his modesty prevented him from appealing to his friends. His allusion to this, and his gratitude to God for what had already been done for him, was well expressed in his letter to GLEANINGS in 1892, and will be found on page 609.

My own acquaintance with Mr. Langstroth was through our correspondence. I had always admired his book, not only for the information it contained, but also for the purity of its phraseology, which placed it at the head of all American works on apiculture. In my correspondence with him I found he was not only a great bee-master, but also a thorough Christian gentleman. I have always regretted that, when I was in America, I was not able to see him, owing to his suffering at the time from his head trouble. I have had a good many letters from him, and on my return from Africa he thanked me most heartily for investigating and reporting upon the merits of the bees of Northern Africa. It was only quite recently that I had several letters from him, and among other things he invited me to be present at the meeting of the North American bee keepers' convention at Toronto. He also asked me to make some experiments in feeding bees with malted milk, which he had been using with benefit to himself. He had been reading my book, "The Honey-bee," and, referring to it, he observed, "What I wrote to you about the malted milk meets with confirmation in

what you say about chyle food. Let the mixture be made with hot honey-water, and how near it seems to come to chyle!" I regret that this was his last letter to me, and that, since its receipt, I have not had the opportunity of trying the experiment. He also told me that he had written confidentially to several friends, and had asked them also to try the experiments; so if any thing comes of it I hope Mr. Langstroth's name will not be forgotten in connection with it.

I hope you will excuse me for writing so long a letter. I could say much more, but I am sure there are others, much more qualified, who have been intimately associated with him, who could give far more interesting reminiscences of him than I am able to do. I was, however, glad to be able to write a few words in testimony of what Mr. Langstroth had done for apiculture, and also to show you the respect we have entertained for him, and the admiration with which we have looked upon him in this country.

We can truly sympathize with our American brethren in the loss which they, as well as bee-keepers generally, have sustained.

31 Belsize Park Gardens, London, England.

[Mr. Cowan refers to a letter of Mr. Langstroth, regarding malted milk and its relation to bee-food. A similar one was sent to us; but at the time he was not ready to have it made public; but since his death we give it here just as he wrote it.—Ed.]

I have something to communicate which may interest you. A few nights ago, as I lay upon my bed, a thought suddenly darted into my mind. I have not time to tell you what suggested it, and perhaps I have made a discovery which will be highly important to bee-keepers. Read what Thos. W. Cowan says about the chyle food the bees feed to the larvæ. Then read what Horlick says about malted milk. Now let the powdered article be diluted, not with simple hot water, but with hot honey-water, and don't you see that you have almost the exact equivalent of the chyle food given to the larvæ? This is not an expensive food, and, pollen or no pollen, weather good or bad, inside the hive we can feed what may be the best stimulant to brood-rearing. Given a food of such value, not too expensive, and so easily prepared, and what consequences may not flow from it? I need not attempt to describe—they follow like the corollaries from the demonstrated problem.

I write to you, among other dear friends, to put this thing at once to the test—feed as you know how to do—note its effect upon brood-rearing as you may easily do in a short time. The season is right; the time before the Toronto convention sufficient. Most experiments require much time, patience, etc., before we can arrive at any certain conditions; but if I had bees, and dared to do any thing with them, without too much risk, I should be able to say in less than two weeks, "Eureka!" or "fooled again." I have set so many at work that we must arrive at certainties.

If it is a success I shall give it to the bee-keeping world, at the Toronto gathering. I would dicker

L. L. LANGSTROTH IN HIS 82^D YEAR.

with nobody, and have no doubt that I should be amply rewarded.

I am concerned to see that your health is not firm yet. I have found great help from the malted milk. Might it not benefit you?

I say, mix with honey—not sugar—for honey, as you know, is a partially predigested food, according to Prof. Cook and others. L. L. LANGSTROTH.

Dayton, O., Aug. 19.

[At the time this was received my health was such that I gave very little attention to business, and among other things this was passed by. If others have tried the feeding as suggested by our departed benefactor, we should be glad to hear from them.—ED.]

LOOKING BACKWARD.

A REVIEW OF APICULTURE IN OLD TIMES AND IN OLD COUNTRIES.

By Charles Dadant.

The men who, instead of destroying their bees, conceived the idea of domesticating them in order to get the crop of honey without so much work, made use of hollow tree trunks; after that they made hives of baked clay, of wickerwork, of straw, of cut stone, and of boards, etc. Unfortunately it was difficult to get the honey without destroying the bees. Besides that, the wax being greatly sought after, especially for use in churches, where no other kind of illuminating material was employed, its value prompted bee-men to suffocate their bees in order to rob them of their stores. I should add here, that, in the greater part of the countries dominated by Catholicism, this massacre of colonies was inevitable, for their laws forced the inhabitants of villages to furnish the churches so many hundredweights of wax every year. It was thus that the destruction of the richest apiaries became a lucrative business, as it is to-day in France, in Gatinals, near Paris, where there are professionals who make a business of laying out apiaries, and who are supplied regularly by persons who raise bees, not for their honey, but for the purpose of selling them when the hives are full.

In proportion to the spread of bee culture, their habitations were improved. Particularly was this the case in Greece, where a knowledge of their habits and the methods of culture was developed.

Della Rocca, in 1790, relates that the apiculturists in the Cycladean Archipelago, in Greece, used long hives of baked clay, which they placed horizontally through the thickness of walls which were made expressly for that purpose. The bottom of each hive was removable, and one could get the honey almost without disturbing the bees, and without being subject to the stings of the bees as they issued from the front end of the cylindrical hive. He showed also a board hive, the frames of which were upheld by means of small top-bars or slats, under

which, and attached to them, the bees built their comb.

Hives with movable frames were still in use in Greece in Della Rocca's time, made after another fashion; for Liger, in his "Rustic House," printed in 1742, shows the design of a hive, with entrance, made of wickerwork, and furnished with top-bars from which were suspended the frames. The progress of Greece in apiculture need not surprise us when we remember that, 300 years before the Christian era, Aristotle had already published some descriptions of the habits of bees.

If we refer to the ancient writings on apiculture we find that movable frames were not used in other countries until much later. Those who suffocated their bees, or those who sold bees to those who did so, did not have, and do not now have, hives with more than one compartment. Others, finding this practice cruel, or desiring to preserve their colonies, placed surplus-cases on top of the hive-bodies; afterward, hives with several divisions, or "stories," "horizontally divisible." Afterward some were constructed with two vertical divisions; then with three. Huber, toward the end of the last century, in order to study the habits of bees, made what is known as the "leaf" hive, which one might open as he would the leaves of a book as it stands on end.

Finally in Germany, Dzierzon published, in 1846, a description of his hive with movable frames, which opened from behind, and the frames of which were supported simply by little bars.

In the same year 1846, Debeauvoys, in France, published a book in which he described his hive with movable frames which were removed at the side. I have already related in the journals how I became acquainted with Debeauvoys and his hive. It was in 1849 that I visited the Paris exposition, when I saw, at the end of the hall through which I was rambling, a magnificent comb of honey on top of a board hive. Without paying any attention to the rebuffs which I met in my efforts to get near the hive, I pushed through the crowd. The exhibitor, Mr. Debeauvoys, was not there. One of his neighbors was there with an artificial brooder, in which chickens were hatched every day. These little chicks were perched on top of the brooder, and looked quite forlorn in their seeming distress at finding themselves in the midst of such a scene. Their owner said to me that the bee-keeper would be back soon. Sure enough, Debeauvoys, a rather heavy man, with pleasing figure and lively deportment, arrived in a few moments and explained to me his hive and its manner of manipulation. It was a frame hive, opening at the sides, and it lacked nothing to make it practicable except a space between the ends of the frames and the hive; for the frames, having no top-bar longer than

their width, were supported by lengthening the side-pieces, thus forming feet, touching at the ends the boards forming the front and rear of the hive. To get them out it was necessary to separate them from the walls of the hive by spreading the latter a little by means of a thin chisel-shaped lever. This plan succeeded very well so long as the frames were not propolized to the inside of the hive; but after that, their removal was difficult, if not impossible, without breaking the frames; so, although the Debeauvoys hive may have met with some favor in France for several years, and although his book has passed through six editions, the hive was soon abandoned as impracticable. This hapless invention had one unfortunate effect; namely, that of setting French bee-keepers against the use of movable-frame hives entirely, thus retarding progress.

Debeauvoys sold to me the second edition of his book for 45 sous. On returning home I tried to make some of his hives, and transfer some colonies into them. Following the advice of Mr. Debeauvoys I did the transferring by night. It is to be remarked that I received no injury from stings. In the mean time I succeeded nicely. For one or two years I was proud of my hives, and showed them to all who desired to examine their interior. Unfortunately, two or three years after that, we had a very mild winter, not to say a warm one. The fields of rye headed out in January. My hives were filled with brood in March; then a succession of very cold days in April caused the destruction of the twigs of the trees, which were as fully grown as they usually are in June. Then there were seen, instead of green leaves, young shoots blackened by the frost, hanging from the branches which gave them birth. Being too busy at that time to give my bees the attention they actually needed in order to regain the lost ground, I lost them all; and from that time on I had nothing more to do with bees until my arrival in the United States, in 1863.

Having procured the works of Langstroth, Quinby, and King, I immediately perceived the immense superiority of the movable bottom, and the space between the ends of the frames and the inside of the Langstroth hive. There arose, at this time, a discussion concerning the Langstroth patent, as to the priority of the invention of the frame hive with a space between the frame and the sides. King pretended that Berlepsch, a German bee-keeper, had anticipated Langstroth. But it was proved that Mr. L. had applied for a patent about six months before Berlepsch had invented his hive. Besides, the Berlepsch hive, although having been generally adopted in Germany and Italy, could not for a moment stand any comparison with that of Langstroth. Its bottom-board is fixed; it opens behind, so that, if one wishes to see the front frame, he finds it necessary to take them all

out. The frames of the Berlepsch hive, being taller than they are broad, its surplus frames are smaller; and, besides, they are very limited in number, as the bottom of the hive is not movable.

In spite of the ill will which certain owners of the German hives showed, a comparison between the two hives, the Langstroth and Berlepsch, being entirely to the advantage of the former, it has gained a footing in Europe. I am proud to have been the first to describe and recommend it in France, where its distinguishing features—a movable bottom, and frames with spaces between them and the sides of the hive—have been adopted by all advanced bee-men.

The name of Langstroth is known and revered, not alone in North America, but in France, Switzerland, Belgium, Italy, and even in Russia, where the French edition of "Langstroth Revised" has been translated into Russian, in which language it has reached its second edition. Many apiculturists having described the qualities of our lamented friend, it suffices me to say that my son and I are happy to have been deemed capable by him to put his book, which was so far in advance of the times at the date of its first publication, abreast with all that has been achieved since; and above all to have succeeded in spreading its renown in all countries where the English language is known, and where he is considered, as well as in the United States, as a superior man, distinguished for his intelligence, his knowledge, his disinterested and unceasing work directed toward apicultural progress, to which he had devoted his life.

Hamilton, Ill.

HOW LANGSTROTH WAS REGARDED IN GERMANY.

By C. J. H. Gravenhorst, Editor of "*Deutsche Illustrirte Bienenzeitung*."

It was with sincere regret that I learned of the death of Lorenzo Lorain Langstroth. Every bee-keeper in the Old and New World, who knows what this grand and noble American apiarian has done for advancing modern bee-keeping, will feel as I do, and not the least my brother bee-keepers in Germany.

Many years ago, when the late Samuel Wagner founded the *American Bee Journal*, I became a reader of and contributor to it, and in that way I learned what Langstroth had done and was doing to encourage bee-keeping, especially when I received the first edition of his classic and renowned work, "The Hive and Honey-bee." I remember as if it were but yesterday when I received the book, and I would not lay it down till I had read the last word in it. How many times I have since read those wonderfully written chapters, the 11th, on the loss of the queen, and the 13th, on "robbing,

and how prevented," and others. I thought I could do nothing better than to acquaint my brother bee-keepers in Germany with Langstroth and with his system of bee-keeping. So far as I knew, no one in Germany had read any thing of value about American bee-keeping, up to that time, in our bee-papers. Only Pastor Kleine, at Luethorst, had received a few copies of the *American Bee Journal*, from Samuel Wagner. While visiting Kleine I saw the *American Bee Journal* and Langstroth's book, "The Hive and Honey-bee." I translated some articles from those journals, and now and then some chapters from the book mentioned, for German bee-papers. Later (thirteen years ago) I founded the *Deutsche illustrierte Bienenzeitung*, and thought I must do more, especially as American bee-keeping was making such extraordinary progress. In the first annual volume of my journal, I gave, in one of the first issues, a sketch of the life of Langstroth, with his portrait. I did the same in the first volume of my "Imker Album," that contained sketches of the most renowned bee-keepers of the world. In the third and fourth edition of my manual of bee-keeping, "Der practische Imker," one will find a portrait of Langstroth, as well as a representation and description of the Langstroth hive. Since that time, as many German bee-keepers have helped me in that line, I can safely say that American bee-keeping and its great promotor, L. L. Langstroth, are well known in Germany.

And now let me say right here, Langstroth was one of those bee-keepers to whom is due a place in the front ranks of bee-keepers the world over. He is, of course, the Dzierzon and Huber of America. His invention of a most practical bee-hive has, especially in America, raised bee-keeping to a very high degree. If I am not wrong, Mr. Langstroth gave his hive to the public in 1852, seven years later than Dr. Dzierzon did his movable-comb hive; but there is no doubt that Mr. Langstroth made his invention without knowing any thing concerning what Mr. Dzierzon was doing; otherwise such a Christian man as Mr. Langstroth has always shown himself to be, both in his public and private life, and in his masterpiece, "The Hive and the Honey-bee," would have given honor to whom honor was due. The difference between his hive and that of Dzierzon proved that plainly.

The Dzierzon hive has fixed top and bottom boards, and two doors (sometimes one) on one or two sides. This hive is longer or higher than wide, according to the standard frames, which are nearly as large as the standard Langstroth frames. If side-storing of the honey is preferred, the Dzierzon hive contains 16 frames side by side in a so-called "lagerstock." On the other hand, the hive has two or more stories in a "staenderstock." All frames in this German

hive hang with the shorter sides above and below, in this way:

Most of the German bee-keepers are of the opinion that bees winter better, especially outdoors, by the use of frames in which the bees may have their winter stores above the cluster.

It is a matter of fact, that most of the bee-keepers in Germany, Austria, Hungary, and German Switzerland, use Dzierzon hives; but in all other lands the Langstroth hive is more in vogue. I may say without exaggeration, that most of the bee-keepers of the world use the Langstroth hive, and therefore are deeply indebted to the great American. But we, though not using his hive, are, notwithstanding, not less indebted to him, as he was the man whose invention developed bee-keeping in a great measure in such a way that we have learned from him and his disciples in many cases.

Wherever one hears the best names of bee-keepers spoken by the bee-keeping world he will never miss the name of Rev. L. L. Langstroth.

Wilsnack, Germany, Oct. 28.

LANGSTROTH'S INVENTION IN FRANCE AND SWITZERLAND.

HIS BOOK THE "MASTERPIECE OF APICULTURAL LITERATURE."

By Edward Bertrand, Editor of *Revue Internationale*.

Through Mr. Dadant I had already received information of the death of Mr. Langstroth when your letter of Oct. 15 arrived. It was not without deep regret that I learned of the departure of that distinguished man to whom we owe so much; and I can assure you that, on this side of the Atlantic, the loss which the friends of the bee have just sustained will be no less keenly felt than in America; for Langstroth is considered everywhere, in Europe as well as with you, as one of the fathers of modern apiculture. Francis Huber, my fellow-countryman, prepared the way by discovering the secrets of the habits of bees; and, fifty years later, Langstroth, in the United States, and Dzierzon and Berlepsch in Germany, crowned those efforts by giving to apiculturists systems of hives which have revolutionized the keeping of bees. But the manner in which the American inventor solved the problem of movable frames and the inspection of colonies, caused it to surpass the German method; and it is his hives and methods which have been adopted in the greatest number of countries, and which give the most brilliant results. I have, for my part, experimented with both systems; and, without contesting certain merits in the Berlepsch model, I give the preference to the American hive, with loose bottom, and stores above.

But it is not alone for his useful invention that the memory of our great Langstroth deserves to be handed down to posterity. He has written an admirable book in which the elevation of the thoughts equals the extent of the writer's erudition as well as the richness of his observations, and which will remain the masterpiece of apicultural literature. Thanks to Mr. Dadant's translation, of which I am preparing a second edition, this work is now known to French-speaking apiculturists; and it has been produced in Russian through the labors of Mr. Kandratieff.

Our dear master's life had a glorious end, and one well worthy of it, as he died preaching the word of God. Let us preserve his memory in our hearts.

ED. BERTRAND.

Nyon, Switz., Oct. 27, 1895.

SOME RECOLLECTIONS OF LANGSTROTH.

By W. F. Clarke, formerly Editor of the *American Bee Journal*.

My first knowledge of Mr. Langstroth by name was in the early winter of 1863. I had engaged to edit an agricultural journal which was to be started in Toronto, Jan. 1, 1864, to be called the *Canada Farmer*; and on surveying the field of my prospective duties it occurred to me that there was one branch of agriculture about which I knew nothing whatever—namely, bee-keeping. I at once resolved to read up on the subject; and on making inquiries for the best works to peruse I met with “Langstroth on the Honey-bee.” I lost no time in plunging into its pages, which I found replete with interest. The book read like a fairy-tale. I felt as if I had been introduced into a new world. Up to this time my knowledge of the bee did not stand beyond Dr. Watts’ juvenile and moral song, which commences, “How doth the little busy bee!” I now felt that I must explore for myself the new world which had been opened up to me. Toward spring I corresponded with Mr. J. H. Thomas, of Brooklyn, Ontario, and bought of him a colony of Italian bees bred from stock he had obtained from Mr. Langstroth. This was my initiation into what Mr. W. Z. Hutchinson, as I think rightly, calls “the pleasant occupation of tending bees,” the fascination of which is easier felt than told. If it were only for the gratification I have derived from this pursuit as a scientific pastime for more than thirty very busy years, I should feel that I owed Mr. Langstroth a large debt of gratitude.

I first met our lamented friend face to face at the bee-keepers’ convention held in Cincinnati during the month of February, 1871, of which he was elected president by acclamation. His health was poor then, and he accepted office as a compliment, on the condition that none of the active duties of the position were to be performed by him, as he did not feel that he had

physical strength adequate to the task. The convention unanimously consented to this condition. I had a great deal of talk with him about the suit for infringement of his patent rights, in which he was then engaged. He had a deep sense of wrong, and felt most keenly the attempts which were being made to deprive him of what he believed to be his just dues. It cut him to the quick, that the very man who was doing the most to deprive him of the benefits of his movable-frame-hive invention should have placed him before the meeting as an object of charity by starting a \$5000 subscription fund on his behalf. He said he did not want charity; all he asked was justice.

My intercourse with Mr. Langstroth at this time led me to form an exalted estimate of him as a man of high honor, scrupulous integrity, and unbending rectitude. The spirit showed by him toward those who were injuring him was admirable. There was no harshness, no display of unkind feeling, the predominant thought being to have his cause triumph because it was right. There was a lofty dignity and moral majesty about him which impressed me very deeply. I never met him again until in September last at the Toronto convention. He recalled the events that transpired at the Cincinnati convention, nearly a quarter of a century before, and was most profuse in his expressions of gratitude to myself and Mr. A. I. Root for the efforts made by us to have him righted on that occasion. It was a pathetic parting we had at the close of the convention, like that of the Ephesian elders with Paul. They sorrowed most of all that they should see his face no more; and I had the same feeling as I bade him adieu in Toronto, though I did not think the end would come so soon; nor did he. With improved health he was looking forward with almost youthful buoyancy of hope to doing some further work on which his heart was set. But it was not to be. He returned home to die, amid scenes the most hallowed and dear to him, and while engaged in the work he most sacredly loved.

“The weary wheels of life stood still at last.” As a Canadian I am proud and glad that the last public tribute of respect and honor was paid to him, not only on our soil, but amid the classic surroundings of our educational department, where so many busts of departed greatness in literary and philanthropic walks of life are gathered; and I shall take pleasure in moving, at the next meeting of the Ontario Beekeepers’ Association, that permission be sought from the government to add a bust of Langstroth to the collection. I feel sure that permission will be readily granted.

Though I met Mr. Langstroth on only the two occasions to which I have referred, I had correspondence with him at various times as circumstances arose which prompted it. When,

at the request of the North American Bee-keepers' Association, I took charge of the *American Bee Journal*, and removed it from Washington to Chicago, his daughter, Mrs. Cowan, wrote me, at his request, a letter of approval and encouragement, his head trouble being then upon him, so that he could not write himself. He also promised help in carrying on the journal should his health permit. Shortly afterward the sickness and death of Mrs. Langstroth took place, which were a sore trial to him. It was a merciful mitigation of his affliction that his health was so far restored to him that, during the ten day's illness of his beloved partner, he was able to be with her every night but one. The letter he wrote me in announcement of this sad event was a gem in its way. Some passages in it were so beautiful and touching that, though not meant for publication, I took the liberty of inserting them in the *American Bee Journal* for March, 1873. I think it would be an interesting feature in its symposium if GLEANINGS were to reproduce that letter, as it gives a lovely picture of our departed friend's bearing under one of the sorest afflictions that can befall mortals in the present life.

Mr. Langstroth belonged to a class of bee-keepers who are numerous in Great Britain, but comparatively scarce in this country, who engage in the pursuit, not so much for the money there is in it, as for the interest they feel in observing the nature and habits of these wonderful insects, and trying to uplift and ennoble the occupation as worthy a place of honor among intelligent and educated people. It is common in some quarters to despise and disparage this class of bee-keepers; but for what reason I can not divine, so that it is almost necessary to defend the memory of this great and good man from the undeserved obloquy of not being a specialist in this line. He was one of those who do not believe money-making to be the all-important business of human beings in this world. Though he did not enrich himself by keeping bees, he performed services for others, the value of which are untellable. It is a poor return for these services which have done so much to ennoble bee-keeping, both as a science and an art, to belittle the performers of them because they do not count their colonies by the hundred nor their gains by the dollar-and-cent standard. Practical bee-keepers should hail those of the Langstroth class as allies and helpers, and be glad that any and all, according to their several ability, should aid the pursuit.

As a writer, Mr. Langstroth wielded a powerful and graceful pen. He was a master in controversy, and some of his articles of this character, that are on record in the earlier volumes of the *American Bee Journal*, are models of their kind. He did not fear to call a spade a spade. He dealt in no hollow compliments;

and, while respectful and courteous toward all, he spoke the unvarnished truth as he believed it, without fear or favor. Nothing low or vulgar ever marred his writings. There was a charm about his style that could not fail to interest all who read them. A memorial volume, embracing some of his best articles, along with biographical sketches from those who knew him best, ought to find ready and large sale among bee-keepers. I am glad to know that abler hands than mine are to set forth the merits of his invention, and what it has accomplished in the apicultural world; also its relative value as compared with the inventions of others who came before and after him.

I have tried to fulfill the task assigned me, and give "some recollections of Langstroth," and only regret that, owing to my few opportunities of personal intercourse with him, they are so meager. It would be easy to enlarge on the many estimable qualities of our departed friend; but I fear to encroach further on valuable space, and will only add in the words of another: "If I have done well, and as is fitting the subject, it is that which I desired; but if slenderly and meanly, it is that which I could attain unto."

Guelph, Ont., Nov. 1.

—♦♦♦— "LANGSTROTH, THE NESTOR OF AMERICAN APICULTURE."

WHOSE NAME IS KNOWN AND WHOSE WORK IS
APPRECIATED ALL OVER THE WORLD."

By Thomas G. Newman, former Editor of the
American Bee Journal.

This is the subject assigned to me for comment. Other themes presenting the many noble characteristics of the late brother will no doubt be ably introduced by those having them in charge, and so I shall enter at once upon my topic.

Father Langstroth's invention of the movable frame, in 1852, was so perfect, when announced, that time and experiments have not improved it. While in different countries and climates its dimensions have been modified somewhat, yet the movable frame in use to-day, the world over, is substantially the same as Father Langstroth introduced to the world after he had privately experimented and severely tested it, in 1852.

That invention completely revolutionized the pursuit of bee-keeping in all the civilized countries of the earth, and gave it such an impetus that it has now become one of the leading agricultural industries of the world. Its inventor's name will endure as long as bees are cultured, and will be remembered and revered by generations yet unborn.

His classic book, "The Hive and Honey-bee," stands at the head of bee-literature, and has been translated, in whole or in part, into all the principal languages of the world; and on the

natural history and habits of bees is a standard authority wherever bee-keeping is an industry of importance.

Sixteen years ago, when I attended the bee and honey exhibitions in Europe it was demonstrated to my observation that movable frames were universally used; and whenever the inventor's name was mentioned it was cheered to the echo. In England, Scotland, Switzerland, Germany, Austria, and Italy, I found enthusiastic admirers of Father Langstroth, who truly loved him for his apicultural inventions and his pure and benevolent character.

Unfortunately Father Langstroth was not a millionaire, nor did he possess enough in his old age to secure even the necessities of life. He had been too liberal and unselfish in his prime to even think of age or want.

In each of the countries before named, it fell to my lot to state these facts when in the assemblies of representative apiarists. To illustrate the esteem in which he was held, let me mention a few instances.

At a banquet in London, given in honor of the American representative to the bee-conventions of Europe, a toast was proposed to the Rev. L. L. Langstroth for his apicultural inventions and genius. Being called upon to respond to the toast, I referred to the misfortune of his poverty, and immediately, in true, large-hearted English style, the whole assembly rose to its feet, cheered his name, and a good contribution was then and there made and sent to Mr. L. to cheer his heart and clothe and feed him during the approaching winter. There were present, not only representative English and Scotch apiarists, but many from Continental Europe, and among these there were four or five editors of bee-periodicals. All were of one mind, doing honor to our loved American bee-master, who has just passed through the gates of Paradise.

At the other bee-conventions on the continent, similar scenes were enacted, particularly in Switzerland and Bohemia. At the latter, the Rev. Dr. Dzierzon (the Nestor of German apiculture) forcibly stated his admiration of Mr. Langstroth, and sent a loving message to him by the writer. Among his other enthusiastic admirers I may mention the Baroness of Berlepsch, Augustus Schmidt, editor of the *Bienenzeitung*, Prof. Sartori, Herr Vogel, Hilbert, and Carl Gatter.

Prof. Butlerow, of Russia, Councillor of the Government, was the bearer from St. Petersburg to Prague of the imperial distinction of the Order of Santa Anna, by order of the late Czar, to confer the same upon the Rev. Dr. Dzierzon for his apicultural research and inventions, and that Russian dignity was pleased to couple the name of Langstroth, of America, with Dzierzon, of Germany, and others, as the greatest men living in the api-

cultural world of the day. He then conferred the decoration on Dr. Dzierzon, with the usual ceremonies.

But space forbids further narration of the many interesting incidents within my knowledge, in proof of the topic assigned to me. I will merely add that the educated and most prominent apiarists of the world, with one accord, attribute to Father Langstroth this well-earned honor: That in his life, character, and labors, he was one of Nature's noblemen—a modest, unassuming, honest man. He has fairly and fully earned the grand distinction of being the "Prince of Apiarists—the Huber of America!"

We should all realize that it is the greatest of all earthly privileges, as well as among the highest of all human duties, to commemorate the life, example, and services of one so devoted to the advancement of apiculture as a science and a pursuit.

He was as confiding as a child, and therefore an easy prey for the unprincipled. At Toronto, the last time he appeared at a bee-keeper's convention, it was a grand treat to listen to his loving words, so entertainingly uttered. Even food was forgotten, though placed before him, when talking with friends and companions.

Some of us donated enough to take him to Toronto, and there a liberal donation was made him. His last letter to me began with these words: "Dear Friend: I can almost see you, and hear your generous remarks concerning me before the Toronto convention," showing how he "lived over again" the pleasant scenes of life, while waiting for the 'change' which should call him to the 'home over there.'" Patiently, lovingly, confidingly, he might say:

Only waiting till the shadows
Are a little longer grown;
Only waiting till the glimmer
Of the day's last beam is down;
Then, from out the gathered darkness,
Bright and deathless stars shall rise,
By whose light my soul shall gladly
Tread its pathway to the skies."

Chicago, Ill., Nov. 18.

FROM MR. LANGSTROTH'S PASTOR.

Rev. W. F. McCauley.

I was intimately acquainted with Mr. Langstroth for the last eight years of his life, he being a member of my congregation in Dayton for over seven of those years. It will be impossible, in the limits allowed in this symposium, to do more than to give some general statements concerning this remarkable man.

He came to Dayton in August, 1887. I last saw him in September, 1895, on the occasion of his visit to Toledo, made while *en route* to the Toronto convention. Twice in the period indicated he suffered from his peculiar physical ail-

ment and its resulting "melancholia. The first of these periods lasted about three years; the second terminated not many months before his death. He derived some temporary help from a physician in the early part of his residence in Dayton, and said joyfully, "I think I am fighting a winning battle." It did not so prove in the end; but we all rejoiced that, after all, the close of his life was free from shadow and gloom. The trouble referred to did not seem to affect his intellect, but was of the nature of depression of spirit, by which he was unfitted for his accustomed tasks. When in the enjoyment of entire health no one could be more active or companionable. Did space permit, instance after instance might be given to show the heartiness of his disposition. Geniality and earnestness were companion traits or ingredients of his nature, and it was delightful to have an intimate association with him. Though he grew to be nearly five years past fourscore, yet there was still much of the dew of youth upon him: he was like a tree bearing simultaneously blossoms and ripened fruit.

He had a breadth of culture and of intellect that marked him as a man among men. He deserves the respect of all, not alone for his achievements along the line of bee culture, but for his general ability and high character. This is the estimate of a friend who knew him in his various moods, and never found him other than true and lovable.

He was frequently reminiscent, and would quote fine passages; or relate anecdotes, of such character that the point illustrated would remain a long time in the mind. He was never unreasonable, but by nature was intense, and that quality endeared him to the writer. He uttered his convictions in unmistakable phrase, and gave others the same privilege. This enabled one to "get on" with him in famous fashion, for no time was wasted in false motions. Kindliness and straightforwardness, discretion and courage, and these dominated by heartfelt devotion to God and his truth, threw about him an atmosphere of light and warmth.

In all the foregoing there is no exaggeration; the effort has been to seek phrases that would convey a just conception of a character honored by one generation, and whose virtues should be preserved for the contemplation of another.

In the Y. M. C. A., in the pulpit occasionally, and in private life constantly, he sought to employ his strength to accomplish good. He was unselfish, and planned busily for the good of others. His life was broken into segments by physical affliction, but he did his best with his opportunities; and through the scattered clouds we can trace the shining arch to its base at the triumphant close of his days. He could say of his heavenly Father:

Better to me than all my hopes,
Better than all my fears,

He builds a bridge of my broken works,
And a rainbow of my tears!

His death came suddenly, like the setting of the sun, which lingers in the horizon, and then quickly drops from sight. His setting, too, was in full-orbed power. He was assisting the pastor of the Wayne Avenue Presbyterian church in the communion service, with three generations of his descendants in the congregation before him, when the moment came that terminated his earthly career—but his "works do follow him." It was the church that his son-in-law, Mr. H. C. Cowan, had helped to found as a Sunday-school, and of which the writer had been pastor. That church had been the subject of Mr. Langstroth's deep interest, and it was hallowed anew by his death. It would be fitting if the church could somehow be made a Langstroth memorial. It must not be forgotten that he was a minister of the gospel, and formerly a pastor. It seems most remarkable that the calling he was compelled to forego in an active sense for so much of his life should receive the benediction of his parting breath. It was thus that he died "in the harness," and left after him an example of devotion in service for all to emulate. His death became an illustration of that providential care which adds symmetry to every devoted life, and satisfieth the longing soul.

Toledo, O.

REV. L. L. LANGSTROTH.

THE MOST WIDELY KNOWN, LOVED, AND APPRECIATED BEE-KEEPER IN THE WORLD;
AN ALL-AROUND GENIUS; THE INVENTOR OF THE FIRST PRACTICAL MOVABLE-FRAME HIVE.

By Prof. A. J. Cook, Author of the "Manual of the Apiary."

It was with keen regret and sadness that I heard, on October 10th, that our old friend and benefactor—Mr. Langstroth was the benefactor of every bee-keeper—had passed to his reward the Sunday before. I had recently had two letters from him, which spoke of health, vigor, and strength. We all know of his long journey to attend the Toronto meeting; and a very dear mutual friend wrote me but a few days before that he had entertained Mr. Langstroth at his house, had taken him for a long ride, and that he seemed very bright and vigorous, and talked of his friends with so buoyant a spirit, and of affairs with such keen mental zest, that, though nearly at the eighty-fifth milestone, yet he seemed likely to see yet many days of usefulness and activity before he passed to the great beyond. Thus it was that the news came to me as a shock; and with the thousands of others all over our great country, I bowed my head and heart with grief and sorrow that I should see the kindly face and hear the sympathetic voice no more.

It is certainly true that the world has never had a bee-keeper who was more widely and justly known, loved, and appreciated than our dear father Langstroth. And so the world never lost an apiarist who will be more widely and sincerely mourned.

I had visited our beloved and venerable friend repeatedly at his own home, and had entertained him at my home on several different occasions. I grew to love him as a dear personal friend, to admire him as a man of very rare native ability and acquirements, to venerate him as a man of the loftiest Christian character. Few persons ever suffered more cruelly at the hands of unscrupulous, selfish, designing men, and yet his great loving heart seemed to harbor no thought of revenge or unkindness. He exemplified, in a manner rarely witnessed even among good men, Christ's words, "Love your enemies, and pray for them that despitefully use you and persecute you." Indeed, he was a rare example of one whose life was wholly permeated and glorified with the spirit of the Master.

There are many men who excel in some one line of work. They may have a genius at invention; they may be wonderful at painting word-pictures, and thus gifted in the art of exposition; they may possess great intellects, and thus become great scholars; they may have that beautiful equipoise of character that insures just judgments, and makes them broadly and grandly influential. But how rare to find these qualities united in one and the same person! Mr. Langstroth was all this. His keenness of vision as an inventor was remarkable; his power as an investigator and writer was graphically illustrated in his admirable work on the honey-bee; his ability and scholarship were known, recognized, and appreciated by all who knew him; while his beautiful character, that thought no evil, could hardly understand or believe that others were selfish, calculating, and willing to take advantage of his unsuspecting nature. His was a great mind, his a true loving heart, he that noblest work of God, a true, sweet, Christian character.

To-day we know positively that Mr. Langstroth was the inventor of the first practical movable-frame bee-hive. The German top-bar hive, with combs fastened to the side, was a previous invention, as was the close-fitting frame of Major Munn; but neither of these was known to him previous to his own invention, and each was as inferior to his as is the sickle to the self-binder. Mr. Langstroth had the vision to see a great need, and the genius to supply it; and in so doing he shared the honor and glory of very few men—that of revolutionizing a great industry, and changing entirely its methods. He did more than this; he did his work so well, that, though nearly fifty years have rolled by, yet no one has been

able in all that time to improve upon his invention in any essential particular. What a compliment to him, that his hive, essentially as it was given to the world nearly half a century ago, is to-day the hive of nearly all our brightest and most successful bee-keepers! No one can gainsay the fact, no one can deny the glory, of such an accomplishment. I can not find a parallel case in all the history of inventions. The sewing-machine, the reaper, the steam-boat, the railroad locomotive of to-day, could hardly claim relationship with the first ones given to the public; indeed, we are told that no one can afford to run a steamship of a score of years ago.

Mr. Langstroth was also an author of the highest type. His "Honey-bee" will ever remain a classic in bee literature. The incisive style, the pure vigorous English, as well as the fascinating subject-matter, alike charm the interest and awaken the deepest admiration. Like another classic, Darwin's "Voyage Around the World," he opens up to us the secrets of investigation, and we are charmed as we discover how his mind worked its way upward in the realms of invention and scientific discovery, and it is equally true that his honesty was as thorough as was his genius at invention or his ability to describe. He was no plagiarist, either as a writer or inventor. Even the thought of claiming the work or thought of others was revolting to him. Had the same been true of others, Mr. Langstroth would have died a rich man. In all his writings he was overscrupulous and particular to give every possible credit to others.

As a student in college, Mr. Langstroth stood among the first. As a teacher in Yale College, his *alma mater*, after graduation he won the respect of all his colleagues. As a preacher he was eloquent, persuasive, convincing. It was my privilege to hear him preach on several occasions, and he always held the closest attention of all his hearers. Except for the mental affliction that weighed him down for so much of his life, he would certainly have gained wide fame as a pulpit orator. He was an intimate friend of the great Henry Ward Beecher, whom he resembled not a little in personal appearance and style of oratory.

Socially Mr. Langstroth was very exceptional. Time always took flight when he became a companion. An hour or even more was all too short for the meal-time when he sat at the board; and the hours for sleep were crowded at both ends of the night when he was an inmate of the home. His wide reading, his knowledge of history, his acquaintance with men, his thorough knowledge of the Bible, and his practical adoption of its teaching and spirit, all combined to make him a delightful and most valuable and entertaining companion.

His lifework specially endeared him to bee-

keepers. His invention and discoveries were a special gift to every progressive bee-keeper the word over. He personally contributed to the success and happiness of this entire class. No wonder that they loved him with genuine sincerity. No wonder that they mourn his loss with sincere sorrow. It is good that he could be present at the last meeting of the North American Association at Toronto. It will remain with us a pleasant memory that he died while administering the communion, and commending the love of the blessed Master, whose love came with such a rich effulgence in his own life, and through him spoke as a blessed benediction to all who knew him or came under his beneficent influence.

Claremont, Cal.

RECOLLECTIONS OF L. L. LANGSTROTH.

AN INTERESTING INCIDENT; LANGSTROTH AND HIS STATEMENTS CONCERNING THE HEDDON HIVE.

By Thaddeus Smith.

It was early in the sixties, or it may be a few years before, that I first heard of Langstroth's book on the honey-bee, and of his moveable-comb hive, and, being previously interested in bees, I procured the book and the hive as soon as possible. I was probably the first to introduce the Langstroth hive in Kentucky, sending to Cleveland, O., for them. I now have some of those hives on Pelee Island, Canada, that I took there with me. However, they are not in use.

Since then the name of Langstroth and hive have been familiar household words in my family; but I never had the pleasure of meeting him until at the late convention at Toronto. I there made his acquaintance, and, being afflicted with deafness, like him, he seemed drawn toward me, and one day at the hotel he invited me into the parlor to have a talk with him. When we had discussed our ailments and the best aids for hearing, etc., the talk turned to other subjects. He told me that he felt perfectly well—strong in body, and clear in mind. Talking about being able to hear some voices much easier than others that might be of a higher pitch, he told me of an incident of a deaf woman he was once in his ministry called upon to pray with. He said he had a very strong voice, and that he knelt down close by the side of the woman, and spoke slowly and distinctly; and when he was through, the woman declared that it was the first prayer she had heard in many years; that it was almost miraculous, and she thought her hearing was returning. But he told her no; it was only the way he spoke.

He spoke of bees and hives, and mentioned the injustice done him by some because he approved and recommended the Heddon hive as an improvement upon the original L. hive. He

said he was even accused of being in his dotage, or was bought by Heddon because Heddon paid his traveling expenses to visit him, and was indignant over the matter. After a pleasant half-hour's chat we parted, and he wrote to me, after he reached his home; and in a few days after receiving his letter I saw the announcement of his death.

Midway, Woodford Co., Ky., Dec. 2.

LANGSTROTH'S MESSAGE TO THE SUNDAY-SCHOOL CHILDREN.

By S. T. Pettit.

The bee-keepers of America lost a good man and a friend when dear old Father Langstroth died. His influence was firm on the side of the Holy Bible and Christianity. His noble tender heart overflowed with love for the human race.

When in his presence I always felt an inspiration that I must be a better man in future. At our last convention in Toronto it was my privilege to have quite a long talk with Father Langstroth on religious subjects; and when we got on the subject of Sunday-schools his face seemed to glow as we talked together. And when he found that it was my official duty to visit all the Sunday-schools in the township in which I live, he, with warm animation, said, "I have a message I want you to take to the boys and girls as you visit your schools: First of all, impress upon their tender hearts that the Bible is the *very* word of God—the infallible, immutable word of God; that it is the very voice of the Holy Spirit speaking to our hearts. Then you can show them the necessity of committing largely of that word to memory. Tell them that they can easily do this when young, and that what they learn when young will stay by them; but what is learned when old is soon forgotten and lost."

Then he recited some beautiful poetry, some of which is of his own composition, composed when he was young. He gave these with great ease, accuracy, and beauty. "But," said he, "what I learn when old just goes from me—is forgotten and lost."

Belmont, Ont.

LINES ON THE DEATH OF FATHER LANGSTROTH.

The "Grand Old Man" of apiculture is no more;

Gone is the look of suffering he often wore;

The weary aching head to trouble oft a prey,

Rests in the light and life of heaven's eternal day.

Grand was he in physique, but grander far in mind,

Grandest of all in love and service to mankind;

Free from low aims, unselfish, bent on doing good,
Till, past fourscore, a pillar in God's house he stood.

We never grieve when we behold a shock of corn
That, fully ripe, is to its garner borne;

We raise the song and shout of gleeful "harvest home,"

And fill with strains of music heaven's Empyrean dome.

Thus, like a shock of corn full ripe, our aged friend Attained, 'mid hallowed Sabbath scenes, his journey's end,

While those who watched his exit, with tear-moistened eye,

Soliloquized, "Let me like Father Langstroth die!"

If "Death ends all," we never more again shall see

That form erect with conscious moral majesty;

But if our Christian faith tells no delusive tale,

We in the glory-land shall bid our friend "All hail."

Will there be bees in heaven, and honey gathered there?

Is it a "happy hunting-ground," without a care?

We know not; but our friend will reap a rich reward Of joy and fellowship, "forever with the Lord."

Farewell, dear friend, and in a brighter world than this

May we enjoy with you a life of perfect bliss,

Where thrilling music through celestial mansions rings,

And pleasures evermore are gathered without sting!

WM. F. CLARKE.

Guelph, Ontario, Nov. 18.

[This memorial would be incomplete without at least a mere reference to the life and work of one who was cotemporary with Father Langstroth, and gave him material aid and encouragement in his early labors. I refer to the founder of the *American Bee Journal*, the lamented Samuel Wagner—that prince of bee-journal editors, scholar, and bee-keeper. The early volumes of the "Old Reliable" under the editorial management of this man are a veritable storehouse of valuable information. As one glances over them he begins to wonder if we are so very far in advance of them to-day in our knowledge and practice. The fact that apiculture took such a wonderful impetus in this country in the early sixties is due very largely to the unremitting and unselfish labors of these two men. The one gave us the invention which revolutionized modern bee-keeping, and the other spread the knowledge of that invention over the whole wide world. Wagner saw at a glance the value of the movable frame; and during the darkest hours, amidst the persecution against Mr. L.—a species of blackmail that has been characterized as a blot and a disgrace upon our early apicultural history—this man Wagner stood by him through it all.

In the old *American Bee Journal* for March 12, 1872, we find this beautifully written tribute to the memory of Wagner, by Father Langstroth himself.—ED.]

DEATH OF SAMUEL WAGNER.

READERS OF THE BEE JOURNAL:—Your dear old friend, the honored editor of the *American Bee Journal*, is dead. On Saturday, February 7th, he awoke early, partially dressed himself, and was talking pleasantly with his wife, when he was suddenly seized with shortness of breath, soon became unconscious, and in less than fifteen minutes breathed his last. The physicians pronounced his disease to be aneurism of the heart. He had complained for more than a year of pain and numbness, interfering greatly at times with the use of his pen.

A noble, unselfish, good man has fallen, in the full vigor of his intellect, with judgment unimpaired, and memory wonderfully tenacious. Nearly seven-

ty-four years old! How few of the readers of the *Journal* could have imagined that its vigorous editorials and wise management were the products of a man who had reached an age when most men are comparatively useless.

If he could have chosen for himself, it would have been to die thus with the harness on; to pass by the shortest transition from useful happy work to the better land.

Few know how much Mr. Samuel Wagner has done for the promotion of bee culture in America. Being able to read German fluently*—indeed, until he was nearly ten years old he spoke no English—he had taken all the numbers of the *Bienenzeitung* and other German bee-journals, from their origin. His library is unquestionably the choicest repository, in America, of German bee literature, and probably the fullest, in this department, of any private library in the world. Better acquainted with the history and literature of bee culture than any man in America, perhaps than any living man—seldom if ever forgetting a single fact once lodged in his extraordinary memory, he was so modest and reserved that only those who knew him well understood the wide range of his reading and investigation.

Unselfish to an unusual degree, he cared comparatively little for money or applause, but kept steadily in view the advancement of the true interests of bee culture, making his varied information contribute to the wider diffusion of all that pertained to the true theory and practice of his favorite pursuit. While specially familiar with every thing pertaining to this subject, he was well versed in the civil history of his country, and intimately with the ecclesiastical history of the German Reformed Church, in which he had served for many years as an honored elder. There were few subjects, indeed, on which he could not converse with ease; and by the extent, variety, and remarkable accuracy of his information, he was one of the most delightful companions to all who enjoyed the pleasure of his acquaintance.

It is very difficult to realize that all these stores of instructive and entertaining knowledge lie buried in his tomb; and nothing but a firm belief in the wisdom and goodness of that merciful Father, in whom he trusted, can reconcile us to his loss. He who hath brought "life and immortality to light in the gospel" knows best when and how to summon his children to their unclouded splendor.

L. L. LANGSTROTH.

[After the above the following appears, written by Mr. Wagner's son:]

Samuel Wagner was born at York, Pennsylvania, August 17th, 1798. His father was at that time pastor of the German Reformed Church in that borough. Having accepted a call from the German Reformed congregation at Frederick, Maryland, he removed there. Mr. Wagner there attended the parochial school attached to the church. In 1810 his father resigned, owing to ill health, and re-

* We forgot, in the February number of the *American Bee Journal*, to give the proper credit to Mr. Wagner for his translations from the *Bienenzeitung*, given in the article on the Berlepsch frames.

* It is with deep regret that we announce that no likeness exists of our venerable friend. He shrank so instinctively from every thing having the least appearance of personal display, that he could never be prevailed on to allow his portrait to be taken.

turned to York, where he shortly after died. Mr. Wagner was then sent to the York County Academy, where he received his education. After leaving the academy, he engaged for some years in mercantile pursuits. In 1824 he purchased the *York Recorder*. In 1829 he sold the *York Recorder* to Mr. C. Hamley, and removed to Lancaster, where, in 1830, he established the *Lancaster Examiner*. Receiving the offer of the cashiership of the York Bank, he sold the *Examiner* to Hammersley & Richards, and returned to York, holding the position of cashier till April, 1862. In 1863 he accepted the position of disbursing officer of the Senate. Resigning this position in 1868, he, for the few remaining years of his life, devoted all his energies to the editing and management of the *American Bee Journal*, which was to him a labor of love.

RAMBLE 145.

By Rambler.

If we could get them all together, there would be quite a congress of lady bee keepers in the United States. Some of these ladies are already known through the journals, but the greater share of them shun publicity, and are working quietly over their apiaries; and the results of their labors are known only in their immediate neighborhood.

One of these quiet, effective workers is Mrs. W. E. Clark, of Bloomington, Cal. Mr. and Mrs. Clark have been mentioned from time to time in Rambles; and what I have to say about them this time is in relation to the present season's yield of honey and its source.

I happened along with my camera at a very opportune moment, and the photo I present represents a condition that can be observed with varying phases upon the outskirts of all Southern California apiaries that are worked for extracted honey.

From the little extracting-house, and the tank outside, the honey is drawn into the 60-lb. tin cans; and as soon as cased it is ready for market.

Mrs. Clark manages the apiary from early spring until the honey is ready to case. Then Mr. Clark is called upon to exercise his lifting talent. At other times masculine humanity is not tolerated in the apiary.

From 80 colonies, spring count, which have been increased to about 120, Mrs. Clark extracted a carload, or nearly 12 tons, gross weight. It is needless to say that there is not much recreation indulged in during the honey-flow; but just as soon as the extracting season is over, Mrs. C. spends a few weeks at the seashore, and recuperates from the summer's labor.

So to Mrs. Clark in particular, and the lady bee-keepers in general, I will doff my hat and utter the following toast:

To chase the clouds of life's tempestuous hours;
To strew its short but weary way with flowers,
New hopes to raise, new feelings to impart,

And pour celestial balsam on the heart,
For this to man was lovely woman given—
The last, best work, the noblest gift of heaven.

The honey secured around this little range of hills is in quality amber and light amber. Water-white honey in California is produced exclusively from the sages; light amber is a mixture, for the greater part, of the sage honey with the darker or amber from other plants. Later on, when the sage bloom is passed, then nearly all of the honey is amber. By this admixture we get several grades of honey; but for marketing, it will all come under the three grades mentioned above.

The sages have been so thoroughly written up and illustrated in bee literature that the reader outside the sage districts might readily imbibe the idea that the sages are the only honey-producing plants in California.

CALIFORNIA WILD BUCKWHEAT—HEADS OF BLOSSOMS.

While the sages do produce a large amount of beautiful honey, there is as great (if not greater) a honey-plant that has received but scant attention and no praise whatever; and I find that it is not even mentioned in any of our standard books upon bee culture. Desiring to do justice to a meritorious plant, and place it beside its more distinguished rivals in its true light, I present the photo. of *Erigonum fasciculatum*, or California wild buckwheat.

This shrub belongs to the buckwheat family,

MRS. W. E. CLARK, AND CARLOAD OF HONEY.

and grows profusely upon all wild land in Southern California, with the exception of a few localities. It seems to thrive equally well upon the mountain-side and in the valley; and the nearer we get toward the Mexican line, the larger the growth. When in full bloom it is one mass of flower-heads, each head a tangled compact mass of little pinkish-white flowerets resembling the blossoms of the cultivated buckwheat. The flower-heads are a study in themselves, taking the various fantastic shapes of wreaths, rosettes, shields, etc. It does not burden the air with such a strong odor as the ordinary buckwheat, and would be scarcely detected by the scent.

The bees work industriously upon these blossoms; and from this source come the great yields of amber honey. It is not only profuse in bloom, but it holds its blossoms and honey

and give a fair yield of honey. It is a common remark here, with our older bee-keepers, that a range in which we find the sages, wild alfalfa, and wild buckwheat, can nearly always be depended upon for something of a honey-yield; and it is a bad season indeed when the buckwheat refuses its drops of nectar. There are, perhaps, many localities where the plant is sparingly distributed, or wanting altogether; but the same must be said of the sages and other plants. I conclude, however, that the wild buckwheat is more evenly distributed, and covers a greater area, than any other plant, and is the greatest and most reliable honey-plant in Southern California; and if there are any dissenting or consenting views among my California brethren in relation to this statement, I trust they will let them be known.

CALIFORNIA WILD BUCKWHEAT (*ERIGONUM FASCICULATUM*.)

production longer than any other plant in California. From early in June until into August it has this year made the hive overflow with sweetness and the bee-keeper sing paeans of joy.

Ordinarily this plant fails to secrete nectar from the 1st to the middle of July; but after a wet winter, and after late rains, it yields honey in a prolonged ratio. In places where there is much natural moisture it seems to bloom indefinitely; and I have no doubt that, if a field of it could be put under irrigation, it would yield honey several months. The honey is not so dark, and the flavor not so rank, as that from common buckwheat. The flavor is mild, and many people prefer it to the white honey, which, in many instances, has but little flavor.

Bee-keepers cite many instances where the sages have failed to secrete honey; then a little later the buckwheat would come to their rescue

In relation to the sages, I note in *GLEANINGS*, page 770, Mr. Israel entertains the same opinion that I did of white sage until I saw the bees doing such good business upon it. In the locality I referred to, the bees worked the black sage first; then there were two weeks of uninterrupted flow from the abundant white sage, before the buckwheat came into working order. The bees would flit up the long stalks of white sage from flower to flower, like climbing the golden stairs. The result is some of the most beautiful honey Mr. Israel could wish to examine.

A word to the reader: In studying the figures at the head of this *Ramble*, the reader will notice that it enumerates 145; this divided by 24, the number of issues per year, results in six years and one issue over. For six years, then, I have been a regular contributor to its columns.

In a recent letter to the editor I suggested that the readers would probably be pleased with a change or a stoppage altogether of *Rambles*, and allow the space to be filled with articles from new writers who are coming to the front.

Then, again, it looks as though my travels would not be so extensive as they have been. I have a growing apiary which will hold me down a good share of the year. So, with a few more scratches of the pen, perhaps the long-suffering readers would feel a relief to find the farewell scratch.

THE PRESENT STATE OF THE ART OF WINTERING.

THE SYMPOSIUM IN OUR ISSUE FOR NOVEMBER
15TH REVIEWED AND COMMENTED UPON

By Dr. C. C. Miller.

[It will be remembered that Dr. Miller was to review and bring out the salient points in the discussion from some of our prominent and successful bee-keepers as recently given, and present them in a new light before our readers. This he has done, and the subject is now so well digested that it will be easily assimilated by all, I trust.—ED.]

At the close of the symposium on wintering, occupying ten pages of *GLEANINGS* for Nov. 15, the editor begins his remarks by saying, "It is encouraging. . . ." Without quoting his remark any further, I think those three words may be applied to the whole of the symposium. Careful examination of the articles shows less conflict of opinion than formerly prevailed. Some emphasize one point, some another; but where a man is silent on any given point it is probably because on that point he is in accord with the majority.

It's very cool of you, Mr. Editor, to give a comprehensive *resume* of the series, then say you want me to give the solid meat. Figures of speech aside, all I can do is to look the ground over and see what there is to talk about. To this end I have taken a piece of paper two feet square, written thereon a number of the points mentioned, then put down under each heading the views of the different writers. The remarkable thing about it is to find, as already intimated, so little clashing between them.

FURTHER DISCUSSION.

Let me begin at the very last end, the last line of the editorial comments, "the subject will be open for further discussion if thought necessary." I sincerely hope it will be thought necessary. Wintering has been so thoroughly discussed in the past that it needed a rest. It's had the rest, and may come up again with some degree of freshness. Its very great importance for all living north of a certain degree of latitude makes it worth while to discuss even very small points.

Now, making a big jump back to the beginning, there is found a change of opinion that has been silently but surely taking place as to the time of *beginning* to get ready for winter. Some place the date at about the middle of September, while others say at the time of taking off surplus-arrangements. Very likely the two agree, and those who say the middle of September are in the habit of taking off *supers* at that time. With others, who have no fall flow, the date may be in August.

AMOUNT OF STORES.

Besides having winter stores in place early, emphasis is put upon the matter of having not only enough, but an abundance of stores—not only stores to last through the winter, but to last through the critical time from the first flight in spring till the main harvest begins. Here, however, there is some conflict of opinion. B. Taylor is convinced "that bees winter better with just enough always accessible honey in their hives to feed them safely until warm weather." Whether his belief is correct

or not, I feel pretty sure that in practice he gives his bees more than he thinks they will use before warm weather, if by "warm weather" he means the time of taking out of cellar; for there is a difference of several pounds in the amount different colonies use; and as he doesn't know beforehand which will be the heavy consumers, he must in his winter preparations consider all heavy consumers. If he gives all enough so that he feels *sure* they will have enough until first spring flight, some of them will have enough to carry them through until the harvest. Whether it is best to have such an abundance in the hive that no colony will need any looking after until the main harvest, is one of the things that may well belong to that "further discussion." Whether my own theory agrees with his or not, my practice agrees at least so far that it is with me a very comfortable thing to know that I have some extra combs of honey ready to be given to any colony that may ask for it before the harvest.

As to the manner of ascertaining the amount of stores, not much is said—the little that is said inclining to the opinion that the colonies are weighed "with the eyes," as J. E. Crane expresses it—that is, by looking in the hive at the frames. Considering the uncertainty of this, unless every frame is carefully inspected, and that even then it's a hard matter to come within several pounds of the exact weight, I can not help thinking that most would prefer to weigh their hives if they knew how easy a thing it is. With a spring balance properly rigged you can weigh the hives with less time and labor than you can take out and inspect the frames. And then there's a comfortable feeling in the thought that you *know*, and that there's no guess about it. True, you'll not know to a certainty just how much honey there is in the hive, but you will know for a certainty the total weight, and from that you can make a safer guess as to the amount of stores than in any other way.

KIND OF STORES FOR WINTER.

As to character of stores, I think no one says sugar is bad; and when feeding must be done in any other way than by giving filled combs, sugar comes first. Of course, sugar or any thing else may be fed so as to do mischief; as, for example, if a very thin syrup be fed very late. C. A. Hatch puts down wild-bergamot honey as "the very best stores," but not many have that. He admits, however, that "sugar stores are all right for winter if fed early, and good sugar is used." But who in this country can tell any thing about what is *good* sugar? In foreign bee-journals, sugar of the right kind for bee-food is constantly advertised; but there is a lack of enterprise, intelligence, or something, among furnishers of supplies in this country. Although B. Taylor thinks honey-dew sometimes good for winter stores, it is no doubt a safe food to leave out of a hive, or to replace with sugar.

BEST AGE OF BEES FOR WINTERING.

The former divergence of opinion as to the best age of bees to winter well seems to exist no longer, young bees being preferred. The younger the better, only so they have had one flight before going into winter quarters. As tending toward this, H. R. Boardman recommends young queens, they laying later in the fall, with the additional advantage of commencing earlier in the spring. Sometimes, however, bees breed too early. B. Taylor, like the reckless youth he is, butts whack against orthodox teaching, by broadly hinting that bees live just as long when busy as when idle; and this in the face of his own statement that most of the bees in a hive May 1 must be seven months old, whereas he will hardly vary much from the general belief that a worker in the busy season lasts only about six weeks. Bro. Taylor, if you don't want to be gibbeted it will be in order for you to explain or recant. In any case, it looks entirely reasonable to believe that in winter there will be fewer deaths from old age among young bees than among old.

AMOUNT OF ROOM IN THE HIVE.

Much weight is given to the matter of having no more room in the hive than necessary, as against the strange teaching of a late writer in *GLEANINGS*, who claimed that bees were warmer in a large than in a small hive. The generally received opinion is that small colonies consume more in proportion to their size than large ones—an opinion that is perhaps tenable, as suggested by J. E. Crane, only when large and small have the same amount of room. In this connection it may not be out of

place to suggest that, in addition to its other advantages, cramming the brood-nest with stores is practically making less room in it for the bees to keep warm. Whether in general a colony may be crowded on so small a number of combs as to be overwarm and restless, as Mr. Crane holds, may be one of the things that would bear further discussion. "Further discussion" is also provoked by B. Taylor's insisting that bees should cluster "over their stores." It seems to me that his bees must have extra training to induce them to pack their stores below the cluster. Better wintering is secured in shallow hives by F. Greiner, and in hives after the Heddon pattern by J. A. Green. This might also awaken discussion.

SPACE UNDER BOTTOM-BARS.

I think there has been a growing feeling in favor of having extra space under the bottom-bars during winter. No one, to my knowledge, ever expressed a belief that it could do any harm, the only objection being the extra trouble. I am heartily with those who think the advantage more than pays for the trouble. Probably there can be nothing better for the bees than the plan of having no bottom-board or floor, and having the hives piled apart so as to have a great space under. I mean just so far as the air is concerned, although on other accounts I prefer the reversible floor-board, which is only a modification of the rim used by others. The reversible floor-board has the rim attached to it permanently, and is especially convenient for those who change their bees from one place to another; for when taken out of winter quarters it can be ready at a moment's notice to be hauled to the out-apiary. Then it's no small advantage to have hives mouse-proof during winter, as they can easily be by putting coarse wire cloth at the entrance of the reversible floor-board. With no floor-board the mice have full entrance to the hives; and although you think you have a mouse-proof cellar, too often you find in the spring that the mice have been playing havoc with your bees and combs. Mr. Pettit's plan of having an opening at the back as well as front gives air with less room if care be taken to have no clogging. Mr. Crane secures much the same advantage by having an extra entrance half way from top to bottom.

SEALED COVERS.

Some time ago sealed covers seemed deserted by their warmest advocates, leaving that apparently as one of the settled questions. But at least one man stoutly stands his ground amid the general stampede, and says sealed covers are all right. Is it worth while to allow the question a place in the realm of "further discussion," just to convince one stubborn man? Hardly, when it's a matter of mere opinion. But when J. A. Green continues to use sealed covers, and uses them *successfully*, and year after year, that single fact, just because it is a fact, leaves the question still unsettled. If he succeeds where others fail, what makes the difference? I think it is perhaps the general opinion nowadays, that in the cellar, sealed covers are all right. What makes the difference between success and failure outdoors? Is it possible that it may be in the packing over the covers? Mr. Green has 6 or 8 inches of packing over, that packing having a rain-proof cover. Have others who have failed used the same packing?

WINTER PACKING.

For outdoor wintering, packing was never more popular than at the present time, and yet I'm not certain that there are not those outside of this symposium who prefer single-wall hives unpacked for the sake of having the advantage of the sun on the single walls in winter. Possibly the matter of latitude may have something to do with this. The editor is right in remarking that "all are agreed that outdoor colonies should be packed in double-walled hives," if in that class of hives he includes single-walled hives with a winter packing around them. Top packing seems to be considered of more importance than at the sides; and where any difference is made there is more packing on top. Pleasant to know that there's such general agreement in preferring planer-shavings for packing-material.

TIME TO CELLAR BEES.

□ The date for carrying bees into the cellar is set by one at Nov. 1; by another at Nov. 15, and by two others at Nov. 20. I feel pretty sure that, if they had taken room to explain more fully, neither one of them would have said he adhered strictly to the

given date. I suspect they are very much like myself. If I were obliged to name positively at the present time the date at which my bees should be carried in next winter, perhaps I should say Nov. 1. But in actual practice the almanac has little to do with it. One year they will be better off to stay out till December, while I have known a year in which every day that the bees stayed out after October was a damage to them. It's a matter of guess at best. Aim to cellar them immediately after the last fly they'll have before December, remembering that one day too late may be worse than five days too early. That is, it won't do as much harm to have them confined unnecessarily in the cellar five days, as it will to be taken in one day after a flight if that one day is pretty cold. As Mr. Boardman suggests, it makes a big difference when they're taken in as to the matter of quietness. After they have had a fly, the first time the thermometer touches 45° you'll find them pretty quiet.

DARKNESS IN CELLARS.

The editor says the underground room for bees should be darkened; but Mr. Boardman gives his bees the full light of day after they are in the cellar, until the weather becomes quite cold. No one, probably, would want his cellar to be light all the winter long; but some think it advantageous to have the cellar light part of the time. I think this view is gaining ground. The late Jesse Oatman told me that a leading bee-journal not far from the State of Ohio once refused to publish an article saying that at times light could be safely let into a cellar, such a view being thought too dangerous heresy to get into print. [It was not refused for heresy, certainly; but if it did not get into GLEANINGS it was probably overlooked in some way, owing to the large lot of unused manuscripts.—Ed.] I believe the admission of light is a benefit, whenever it can be admitted without stirring up the bees. Like Mr. Boardman, I allow my cellar to stand open until the thermometer inside runs below 40°. Toward spring, when a warm spell comes, making the bees uneasy, doors and windows are opened wide in the evening. That raises a general row in the cellar; the bees run all over the hives, and roar enough to frighten a novice. By morning, however, all are quiet, and I've seen the direct rays of the sun shining right into the entrance of a hive without seeming to disturb them in the least. Sometimes they'll remain quiet all day with the cellar light, and sometimes they'll begin to fly out soon after sunrise. As soon as they show uneasiness I close out the light.

TEMPERATURE AND MOISTURE.

Entire agreement as to temperature has not yet been reached. Possibly there might be unanimity as to temperature if all cellars had the same degree of moisture. For a considerable time 45° has been a kind of standard figure, and the symposium still holds somewhere near that for the average cellar. Elwood gets it down pretty fine by saying 38 to 42° for a very dry cellar, 45 to 50° for a very damp one, and 42 to 45° for one of average moisture. But Pettit wants a damp cellar kept down to 40°, giving as one reason that the bees will thus be kept drier; for as air is heated it will take up more moisture. I'm afraid all will not admit the correctness of that philosophy, and I suspect others would want a moist cellar to be kept warmer. Boardman wants the cellar about ten degrees warmer at the last end than through the principal part of the winter, and I suppose most agree in thinking it well to have a higher temperature toward spring—at least, after brood-rearing begins.

VENTILATION.

□ None of the writers ignore ventilation, and perhaps no one nowadays would insist that bees will pass the winter hermetically sealed. So there's progress in that direction. Enthusiasm for sub-ventilation has faded. For one, I should be just as enthusiastic as ever if it were not for the fear that Mr. Pettit may be right in thinking that a gain in temperature is accompanied by a gain in moisture; and, worse than that, I'm a little afraid noxious gases may be taken up in passing through the earth. If provision be made to carry out the air of the cellar, I'm not much afraid about its getting in. And perhaps it's as well to have it come in at a thousand little cracks and through a million pores as to have it come in all at one spot labeled "Entrance."

As to ventilation of hives themselves, there has

been a gravitation toward ventilation at the bottom, and larger entrances than formerly. I suspect convenience has much to do with the matter. I have some doubt whether it matters in a cellar whether the bottom be all open with the top sealed tight, or the top all open with the bottom sealed tight, or whether both top and bottom be open with the air passing through. Only in the latter case there must be so small a passage either at bottom or top that the air will not pass through faster than the bees can use it. In my first cellaring, hives were entirely open at top, and sealed tight at bottom. That is, they were box hives turned upside down. That was Quinby's plan, and it was the most convenient with box hives. With the present hives it's more convenient to have the opening all at the bottom. If the opening is both at top and bottom, it's difficult to adjust it to the wants of the bees. Of course it would be impracticable to have hives all open at the top; but at present the majority think it easier to secure right ventilation by having the top slightly open in addition to the opening at the bottom.

BEHAVIOR OF BEES IN WINTER.

I suspect that at least part of the battles that formerly raged over the matter of hibernation arose from the fact that all did not agree upon the meaning of the word. Very few, if any, will now contend that a bee hibernates as do other animals to which the term is applied. If any one should yet think that a colony goes through an entire winter in a dormant condition, a short time spent in a bee-cellar will disabuse his mind. Whether the guess given in the symposium, that there is a waking-up once a week, is correct, I do not know. I suspect that 24 hours might come nearer the truth. Mr. Pettit takes the ultra ground that not the slightest noise of humming should be heard in perfect wintering. I don't know about that. I do know that I have had bees winter in such condition as I think would satisfy almost any one, and yet I never went into the cellar without hearing what is often called a "contented hum." And yet I must confess that, by looking into a single hive, I could generally see no movement.

FIRE IN CELLARS.

Two in the symposium keep fire in the cellar. I suspect that's a larger proportion than will be found generally among those who cellar their bees. Of those who have tried it and abandoned it, it might not be out of place to inquire whether there may not have been a wrong use of a right thing. Mr. Boardman says it grows in favor with him. I'm not sure whether it does with me, but I'm sure the conviction grows that it is all right. If a cellar stands too near the freezing-point, you can bring the temperature up by making the cellar closer; but you'll have better ventilation and air by bringing up the temperature with a fire. We make fire for folks in winter, and no harm comes of it. Why not for the bees? The fire is put in an adjoining room, not in the same room with the bees. Just why, I don't know. Perhaps the fire is made with wood, in which case there might be too sudden a change of temperature, and the light from the burning wood might be mischievous. For my own use I would no more think of putting the fire in an adjoining room than I would a stove for heating a sitting-room. But I use anthracite coal altogether. A small cylinder stove keeps a steady low fire, and the door of the stove is left wide open all the time. That helps ventilation. I think some fear that bees would fly into the open door, but I never knew a single bee to do so. The fire is kept going day and night all winter long, unless a spell of weather comes that makes the cellar too warm. I may mention that those colonies that stand nearest the stove winter as well as any.

TAKING BEES OUT OF THE CELLAR.

The time mentioned for taking bees out of the cellar is about April 1. Here might be made the same remark that was made about putting bees in. It's a matter of weather rather than one of date. For some years I went by the blooming of soft maple. But that sometimes fooled me, for a cold spell came after they were in bloom, making me wish I had left the bees in the cellar. So now, when the maples bloom, I wait till it seems so warm and pleasant there isn't much chance of more winter weather. That may be when the first maple-blooms show, or it may be two weeks later. And the maples don't watch the almanac closely.

Greiner takes his bees out at night. I prefer Boardman's plan of taking them out on a warm day so they can fly at once. If they are taken out at night, the thermometer may sink before morning below the freezing-point, making each day they are longer confined in the hives worse than a week in the cellar.

Greiner says, "In placing them on their stands I pay no attention to their former location the fall previous." I think some of the bees will go back to their former locations, but I don't know that any harm will come of it. When they first come out of the cellar they seem to be of one scent—at any rate they unite peaceably, and Boardman takes advantage of this to unite at once any that need uniting.

FINALLY.

When I commenced this symposium I thought I could confine to less than a page what I had to say. But I didn't know. I haven't said near all I wanted to, and it's more than a page. You might, Mr. Editor, run it as a serial through the year 1896. Some people like continued stories.

Marengo, Ill., Nov. 25.

[Instead of continuing this in several issues, as hinted by the doctor, I thought we should get a better bird's-eye view to have it all in one issue, and use a smaller face of type. We can't get a bird's-eye view by looking at a spot here and there in the different issues of GLEANINGS. The subject is now open for further discussion. —Ed.]

TENEMENT WINTER CASES.

HOW AN EXTENSIVE BEE-KEEPER OF YORK STATE PUTS UP HIS BEES.

By W. L. Coggschall.

My bees are from 3 to 16 miles from home, and are packed in winter cases with dry sawdust that I keep from year to year. The size of packing-case is 6 ft. long, 2 ft. wide, 2 ft. high on back, and 2 ft. 6 in. on front, and is made of matched pine. Such a box will hold eight 8-frame Langstroth hives, by piling them two tiers high. Slots are cut in the high side, just opposite and corresponding with the entrance in the hive, and a block nailed on so the bees have an alighting-board. When preparing to pack I move four hives out of their position in the row, and then put the case in their place. I now put the four colonies into the case, and shove them tight to the front (my hives do not have porticoes), so the entrances correspond with the slot in box. I take off the enamel cloth and put on brussels carpet, or ingrain; then throw on the sawdust, and pack well between each hive, leaving $\frac{1}{2}$ in. of sawdust on top of the carpet, after which I put on four boards just the size of the bottom of the hive. I now set in four more colonies, and apply carpets and the sawdust. Over the whole I put a water-tight roof. I used shingles at first, but now prefer sheet iron, painted.

After the apiary is a packed I go around and put in strychnine, which is put in cookies prepared at home, to kill the mice. The winter case should be 10 in. from the ground, and I usually raise them up in October. I usually go around once in the winter and clean out the entrances, and put in more poison, and then in the spring, and take out those that are dead,

which is not more than 2 to 8 per cent; then I go and unpack them just as apple-bloom ceases; then they are all full of brood.

Old brussels carpet can be bought of rag-gatherers for 2 to 4 cts. a pound. They will last a long time—5 years if they are put on the bees the same side down that is used on the floor.

Two men can put up for winter 100 to 125 a day, and go eight or ten miles, and can unpack them faster.

West Groton, N. Y., Nov. 15.

[This was written in response to our request for an article for our symposium on wintering that appeared in our Nov. 15th number. As it came too late for that number, we give it here. —Ed.]

THE WINTERING PROBLEM.

AN IMPORTANT SUGGESTION; A UNIFORM TEMPERATURE IN THE CELLAR NOT DESIRABLE.

By R. McKnight.

Of all the problems bee-keepers are engaged in solving in this northern climate, the above is the most important; because successful wintering means a measurably satisfactory honey-harvest. I am not going beyond the bounds of truth when I say the solution of this all-important problem has engaged my own serious attention. I have been so situated that its consideration forced itself upon me.

During the last 15 years I have cared for from 2 to 250 stocks annually. About half of these were kept in my home apiary, where I have a good bee-house especially constructed with a view to successful wintering; and the other half in a yard about 15 miles from home, where there is no suitable cellar or bee-house, and the bees must be wintered outdoors. This has given me an extensive experience in the relative merits of the two systems of wintering.

It is not my intention to here discuss the advantage of the one method as compared with the other, nor to minutely detail the best course to follow in either case; but, rather, let me outline what is necessary to successful wintering under any circumstances. This includes stores, ventilation, and packing (the last is important only in outdoor wintering).

The first essential to successful wintering is plenty of bees, with ample stores against the time of need, which, with me, lasts from October till June. This consists of sealed honey or sugar syrup.

There are other minor matters which need attention, and which will commend themselves to the experienced bee-keeper, but which demand too much space to be here dwelt upon.

VENTILATION.

What type has been employed in printing the opinions of people on this element in the successful wintering of bees! and yet how little we know about it! I was especially impressed by this fact on reading what Mr. Elwood wrote

on page 815 of GLEANINGS. The theory he there broached has awakened in me thoughts I never before entertained on the subject, and may, if true, account for the alleged fact that bees wintered outside are less liable to spring dwindling than those kept in a cellar or bee-house. What is the true theory? It is, as I understand it, that bees, when wintered indoors, should be surrounded by atmospheric conditions, and kept at a temperature sufficiently low to throw them into a state of hibernation, in which the functions of life are partially suspended; that they should be aroused from this state of torpor at regular and necessary intervals; that they may partake of sufficient food to keep them strong and healthy; that they may be aroused to the desired degree of activity by raising the temperature of the repository in which they are kept; that, after having satisfied the demands of nature, they should be returned to a state of quietude and lethargy by again lowering the temperature; and that this should be repeated, when necessary, during the period of confinement; that, being thus kept quiet, and fed when required, they will be put out in the spring well nourished, having strength and vitality calculated to successfully carry them through the trials of spring.

How often these periodical revivals should be brought about, and how long they should continue, remains to be determined by experiment. Mr. Elwood quotes the opinion of the late Mr. Quinby, that "an occasional fire in the cellar is useful." It seems to me this opinion is along the lines of the above theory. We all know bees wintered outdoors consume more stores than those kept inside. May not the cause of this be that, in the latter case, they are subjected to more frequent and more violent changes of temperature, and, in consequence, afforded more opportunities to feed, which may account for their alleged ability to survive the springtime.

If this theory be found to be correct, it will change our present practice materially. The orthodox belief of a "uniform temperature of from 42 to 45°" must give place to a new faith; namely, that *uniformity* of temperature, instead of being necessary to safe wintering, is one of the prime causes of bees being put out in the spring in a weak and debilitated condition, ill fitted to enable them to pull through till bloom time. I may have misinterpreted Mr. Elwood's position; any way, what he has written has afforded me new food for thought on the wintering problem.

MATERIAL FOR PACKING.

This may embrace whatever is used to fill up the space between the outer case and the hive it incloses, as well as the materials employed to fill the cushions placed over the brood-chamber. Any of the materials commonly us-

ed for packing are good enough so long as they are dry when put in, and kept dry while it is in; but there is a great difference in the value of the various materials that are used for filling the cushions. The best of these is carded wool; next in order of value is cork dust. Chaff should not be used. What is needed is something that will transmit the moisture—not absorb it. Dry sawdust, such as is made by ripping up dry lumber in a factory, will serve the purpose. I have tried all these, and I found chaff cushions come off the hives in the spring matted and mildewed, and those filled with wool or cork dust come off as light and dry as the day they were put on.

Owen Sound, Ont.

AMONG THE BEE-KEEPERS OF WISCONSIN.

By Harry Lathrop.

On the 12th of September I started on a trip through the basswood region of Southern Wisconsin. A short account of what I saw and heard may be of interest to the readers of GLEANINGS.

Going first to Wauzeka, Wis., situated on the Wisconsin River, I there took the Kickapoo Valley R. R., which runs up the river 35 miles to a village called Soldiers' Grove, passing through Crawford Co. The valley is narrow in most places, with high bluffs on each side, and one can not see what is beyond these ridges as he rides along. The bluffs abound in basswoods, while the river-bottom is a tangle of fall flowers. I met only one bee-keeper on the way up. I talked with him a few moments while the train stopped at a small station. He did not appear to be a very advanced bee-keeper, and said he did not take a bee-paper. I asked him if he would take GLEANINGS.

"No," said he, "I don't like it."

I asked him why he did not like it, and he replied, "There is too much Christ in it."

How impossible it is to please everybody! But I trust that this brother will soon change his mind, and learn that GLEANINGS is his friend, not only because it will help him to do better with his bees, but because it *has* Christ in it.

From Soldiers' Grove I took the stage to Viola, 15 miles further up the river. From this point the country becomes more beautiful. The hills remind one of the highlands of the Hudson below West Point, N. Y. There is a great

abundance of thrifty basswoods; and the hillsides, being very steep, there will always be much of it that will be left standing.

The stage-driver, I ascertained, was also a bee-keeper. He had about 20 colonies; did not take a bee-paper; said he knew enough about bees to carry him through. I thought I would test him a little, and the following conversation took place:

"Mr. R., did you ever have any experience with foul brood?"

He hesitated a moment, and replied:

"Yes, I had one case last year."

"What do you consider the best way of treating it?"

"I guess the best thing to do is to burn them up. I burned one last year."

I agreed with him that his treatment was all right for foul brood, and he went on to say that he rather thought he had a case of it in his yard at that time, but had been too busy to attend to it; "and," said he, "I have seen cases of it so bad that *they would lay a dozen eggs in one cell.*"

At this point I opened my eyes a little wider, but concluded to say no more on the subject.

In the vicinity of Viola there are several bee-keepers who number their colonies by the hundred, and usually produce good crops of honey.

From Viola I went westward in Vernon Co. to a point near Viroqua. Here I visited Mr. W. M. Cox, who in times gone by has produced some fine crops of honey. The poor seasons of late have somewhat dampened his ardor, and very much reduced his stock. But he intends to build up again, and try to do better. He has taken GLEANINGS for many years, and, unlike the other man referred to above, he likes it *because* it has so much of Christ in it, and says it has been a great help to him in his Christian life.

Returning to Viola, my friend and brother John Willan, who is an evangelist in these parts, took me with his pony team 15 miles further up the river to a place called Rockton. We saw many good locations for bee-keeping; great quantities of basswood in the hills, and very few bees kept. Some of the names in this valley would bring a smile to the face of a judge. At one place John pointed to a small valley entering from the east. "That," said he, "is Goose Creek. A man of the name of Gander used to preach there. On the hill to the north lives a family of Drakes, and a short distance in the other direction is a family of Goslins."

How is that for a web-footed community?

On returning to Viola I visited the home and apiary of Mr. Andrew McCarty, the successor of M. A. Gill, well known to the readers of GLEANINGS. Mr. McCarty has a beautiful home, a good wife, and 200 colonies of bees, 100 of which are in the home apiary, and the rest at a place several miles down the river. He uses the 8-frame Langstroth hive, and works exclusively

for extracted honey, as do nearly all other bee-keepers in this region, extracted honey being much easier to transport to the railroad. Mr. McCarty is one of the very few bee-keepers who produced a crop of honey this year. He accomplished it by moving his bees to a place where the basswood-flowers were not killed by the severe frosts in May.

My next stop was at Yuba, on Pine River, in Richland Co. Here I visited Mr. E. C. Priest, the only bee-keeper in the immediate neighborhood. Mr. Priest had taken only a small crop of honey, and confessed that he had partly neglected his bees for several years back, as he has built and equipped an excelsior-mill, and worked hard to make it a success; but it has not paid. I remarked that he would have done better and had an easier time if he had increased his bee-business, and attended to it properly, and let the excelsior-mill alone, thereby also avoiding the destruction of the basswood timber. He assented that such was the truth. I find the tendency in this country is to neglect the bees for various kinds of ventures. Very few seem willing to make a specialty of honey production, for the reason, as they say, they are not sure of a crop of honey every year.

From Yuba I went down Pine River Valley, passing on the way one of the apiaries of the successful bee-keeper Mrs. Pickard. At Richland Center I was met by Bro. C. A. Hatch, who took me out to his beautiful home and farm. Mr. Hatch is too well known as a bee-keeper to need an introduction here. He and his brother, A. L. Hatch, are extensive fruit-growers. I was surprised to find them successfully producing a large variety of choice apples, plums, cherries, grapes, and small fruits. Of course, the crop was short this year on account of the unusual frosts. Their orchards are situated on the top of high clay ridges, entirely unsheltered. There are many such ridges in Southern Wisconsin, but there are no orchards on them. The apple-trees are usually placed along the creek bottoms, where they do not thrive. These orchards of the Hatch brothers are an object-lesson to the bee-keepers and others of our State, because they show what can be done in our climate; and if there is any branch of business that goes well with bee-keeping I think it is the production of the larger fruits which are gathered after the busy honey season is past. I shall never forget the beauty of these fruit-farms nor the kindness shown me by both the Hatch brothers during my short visit. When I started for home from here, C. A. took me to a small railroad station below Richland Center, and pointed out the place where the out-apiary of the late S. I. Freeborn had made large crops of honey from a kind of mint after the close of the basswood season; but the large number of colonies once owned by him is now greatly reduced. In fact,

the bee-keeping industry is somewhat neglected in these regions, and the amount of honey produced is but a small per cent of what is possible.

In closing I will say that I am not trying to beat Rambler out of his job, though I do enjoy traveling among the bee-keepers, and looking up the resources of my State. I am a married man, and love my home and family, therefore my rambles must be few and far between.

Browntown, Wis., Oct. 23.

THE STEPHENS SPACER.

IMPORTANCE OF GOOD LUMBER FOR TOP-BARS.
AN OPEN LETTER TO DR. MILLER.

By Geo. W. Stephens.

Dr. C. C. Miller:—I see you have dropped the discussion of hives, and taken up frames; and in your article on "The Right Kind of Frames," in GLEANINGS, October 15, you point out an objection to the Stephens spacer. Well, I suppose spacers ought to be discussed along with other things; they are a necessity to any one who is at all particular and cares to have straight combs, and to get rid of propolis. fair discussion will not injure a meritorious article, and I believe in the survival of the fittest; but my mind is not clear as to whether you are putting up one of your jokes, or are in earnest; for, you see, the objection you raise applies to the top-bar and to the man who nailed the frames, and not to the spacer at all. On the same line of reasoning you might say the Stephens spacer will not prevent top-bars from warping. I have some top-bars, made by a popular manufacturer, that are warped, or sprung out of line, $\frac{3}{8}$ inch; but I never thought to blame the spacers. I think it is because they were made of poor lumber, or else it was not well seasoned.

STEPHENS' FRAME-SPACER.

Top-bars should be made of first-clear, well-seasoned lumber; and if pine will not do, something else should be used; and then they should be cut true and to an exact size, and great care

should be used in nailing the frames. I do not think there is any excuse for top-bars varying in width, although I may be mistaken. But if they are cut true to an accurate size, and all alike, I think—in fact, I am sure—your objection to the spacer will be overcome, and you would then secure both fixed distance from center to center and exact space between top-bars, and I believe one is about as essential as the other. The price of the spacers may seem high; but that will be governed by the demand somewhat. When they become better known, and there is more of a demand for them, I have no doubt they can be manufactured and sold at a lower price.

If the end-bar were widened to $1\frac{1}{8}$ in., the same as the top-bar, as you suggest, I doubt very much whether you would find it any easier to nail the frames true; and if the Stephens spacer were to be used, the flanges (or wings) would have to be shortened $\frac{1}{8}$ all around, and the inside lengthened $\frac{1}{8}$, in order to clasp the end-bar. The space between the shoulders of the spacers would then be less than $\frac{1}{4}$ in., and the bees would fill it up with propolis—a thing certainly to be avoided when possible. If the end-bar were made narrower than one inch, the flanges of the spacer would have to be correspondingly lengthened, and would be liable to bend unless made of heavier material, which would add to the cost. So you see I settled on inch-wide end-bars advisedly.

I certainly feel flattered that you find no worse fault with the Stephens spacer, and name an objection that can be so easily remedied, notwithstanding the fault lies elsewhere; but if you were using them on your frames to any extent you would then know what a pleasure it is, comparatively, to handle frames in a nine-frame Dovetail hive, without that superfluous piece of furniture called by courtesy a follower.

Denison, Iowa, Oct. 28, 1895.

[Dr. Miller replies:]

In some respects I think the difference between us is one of words rather than ideas. I admit that, with frames that are made perfect in every respect, the Stephens spacer will not only space correctly from center to center, but will also leave top-bars apart at exact distances. I so stated on page 775. I said, "One of these will secure the other if all frames were made exactly true," meaning the spacing from center to center and the spacing between top-bars.

I can not agree with you that it is as important to have the right distance from center to center as it is to have the right distance between top-bars. A variation of $\frac{1}{16}$ of an inch in the distance between top-bars would be likely to make an appreciable difference as to the amount of brace-combs, while a variation of $\frac{1}{16}$ from center to center would hardly make an appreciable difference in any direction so long as the distance between top-bars is kept exact.

But what we have to do with in actual practice is frames that are *not* true in every respect. At least that's what I've always had to do with. I don't think I ever yet had as many as a hundred frames in one lot that would give exact distances between top-bars by applying Stephens spacers. I doubt whether I ever shall have, and I suspect that I have as true frames as the majority. In such cases, you may lay the blame where you like; the fact remains that the Stephens spacer will not make as good work in preserving an exact space between two top-bars as a nail driven in to the proper depth.

I doubt if any better wood than pine is likely to be used, and I think you are right in believing that the very best should be used, and not poor stuff for the sake of using up scraps of lumber.

You are probably right in settling on an end-bar 1 inch wide as best for the Stephens spacer. But the same reason that makes me want the small space between top-bars makes me want the small space between end-bars and bottom-bars, although the latter is not so important. So I want a spacer that will accommodate the frames rather than to have frames to accommodate the spacer. At the same time I must say that, with frames to suit them, I don't know that any thing better than the Stephens spacer is to be desired.

You are right in saying that, with frames exactly true, the Stephens spacer will secure both correct distance from center to center, and also between top-bars; but any other spacer will do the same with such frames.

The matter of price I did not take into consideration, and it is not my place to meddle with your business matters; but since you have mentioned it—rather the editor first mentioned it—it may not be out of place for me to question the policy you have adopted, that of putting on a patented article (and I believe in patents) a higher price to be paid by those who are first to see its merits and help to introduce it, and then a lower price to others. If I had confidence that an article would become standard, I think I would anticipate its popularity, and make it help advertise itself by selling the first at as low a price as I thought would rule after being well introduced—somewhat on the common principle of introduction prices, which is only one form of advertising. But, as I intimated before, that's none of my business, and you have a right to put what price you please on your own goods.

C. C. MILLER.

Marengo, Ill.

[I consider the Stephens a really good spacer. Perhaps in the line of metal devices it is the best. Although we illustrate it on page 418, May 15th issue for last year, yet for the convenience of our newer readers we reproduce the cut that then appeared.—Ed.]

H. W. SCOTT.

PRESIDENT OF THE VERMONT STATE BEE-KEEPERS' ASSOCIATION.

By A. E. Mamm.

Mr. Editor:—I dislike to do any thing on the "sly;" but sometimes if one can surprise a friend in a pleasing way it becomes gratifying to the performer to do so. Therefore it is with the greatest pleasure that I present the readers of GLEANINGS with a picture of the worthy president of the Vermont Bee-keepers' Association, Mr. Horatio William Scott, who was born at Barre, Washington Co., Vt., Aug. 10, 1870. In the spring of 1884 he removed with his parents on a farm in the town of Williamstown, Vt., where, in the fall of that year, he became the owner of two colonies of bees, although in the spring of 1885 he found himself the owner of only one colony, having lost 50 per cent in wintering. He soon procured Root's A B C and a Clark smoker. Armed with these two very useful and essential implements he studied and

H. W. SCOTT.

worked, and watched and waited, with the result that he secured 75 lbs. of honey, which netted him a profit of \$15.00. With this success the "bee-fever" got full possession of him; and before winter set in he purchased five more colonies, making six in all, which were successfully wintered.

The seasons of 1886 and 1887 proved to be poor ones for surplus honey; but a good increase of colonies was secured. At this point Mr. Scott concluded that it would be to his advantage to work with some experienced bee-keeper. He therefore secured a situation with the writer, with whom he served during the seasons of 1888 and '89. Mr. Scott, being a very apt and diligent student, soon mastered the "mysteries of bee-keeping" so far as they were revealed to his tutor.

I must say right here, in justice to the sub-

ject of this article, that, although I have had a great many students in the apiary, I never had one more diligent and trustworthy than was Mr. Scott. I always found him reliable and respectful in every respect and place.

In the season of 1890 Mr. Scott took charge of and managed the apiary of Mr. J. W. Smith, of Stowe, Vt., with perfect satisfaction to the owner. In the fall of 1890 he entered Goddard Seminary, from which he graduated in June, 1893, having completed a course of 117 weeks in 105 weeks.

On the 27th of January, 1892, he was elected secretary and treasurer of the Vermont Bee-keepers' Association, which office he held with honor and credit to himself and the association until he was elected, Jan. 18, 1895, its president, which office he still holds. He acted on the committee appointed by the association which secured recognition by the Vermont Experiment Station, and in the establishing of the department of apiculture; he having had an oversight of this department for two or three years. Mr. Scott having been a close student of bees and their habits, and an extensive reader of apicultural works, was thus fitted for this position, and for a place in the front ranks of apiculture.

At present Mr. Scott resides at Barre, Vt., where, two years ago, he entered the law office of Burney & Howe, where he began the study of law; and, if I mistake not, has since been admitted to the bar.

He is, or has been, justice of the peace for Washington Co.; a member of the I. O. O. F.; is also a part owner, and clerk and treasurer, of the Acme Granite Co., of Barre.

Although Mr. Scott is engaged in other business, both public and private, he is still interested in bees, and has an apiary of his own which he manages very successfully, keeping well up with the march of progress. Mr. Scott is well worthy of the confidence of all bee-keepers, at home and abroad.

Bristol, Vt., Nov. 25.

HOW LONG DO EGGS KEEP?

HOW MANY EGGS DOES A QUEEN AVERAGE PER DAY DURING THE YEAR?

By Ph. J. Baldensperger.

How long eggs will keep is another many-sided question; for, while in a very cold or cool climate they may be spoiled in a few days if left exposed to cold nights, so will they dry up if left out in very hot weather; while some eggs—I suppose the most vigorous ones—will keep ten days or more in fairly good weather. Out of the number, if you try a comb full of eggs some seem to dry up a few hours afterward, while others stand several days, and a very few stand ten or more days. Sealed brood will resist longer. Even the chilly drones will live as long

as possible. I knew a full frame of drone brood, years ago, in Palestine, which I had discarded, and for the time being I did not know where to put it, so I left it in the honey-room. Well, 17 or 18 days later I went and uncapped the brood and found them as vigorous as though they had just been taken out of the hive. This was in July. Again, this year a colonel bought a hive of bees (Algerine-French) of me. In his absence his gardener wanted to work around the hive, and shut it up, leaving them thus imprisoned for 36 hours in the heat of the July sun. Naturally, all were dead. This was July 20th, 1895. The servant brought me the hive and combs, to give them another stand instead. I had very much to do; and to avoid a bad smell, etc., I gave the five combs containing the dead brood. I knew by experience that such brood of suffocated hives invariably died with the bees. July 30, fully ten days after the accident, I looked for the comb containing dead brood. To my astonishment, more than half were out and crawling out, but in a lamentable condition—dwarfed. The fuzz seemed stuck to the body; the wings were badly developed; they had outlived the catastrophe of their elders, but it was not worth while to have such bees, for they only barely lived.

A queen can lay 3000 eggs a day, but not every day. Here are observations on a colony of bees I followed in Palestine, January to December, 1891. As nearly as I could make out, the colony numbered some 10,000 bees Jan. 1.

	Daily average.	Total.
Average laying from Jan. 1 to 20, '91,	100	2,000
Spring waking-up, Jan. 20 to Feb. 7,	686	11,988
Almond flowers, Feb. 7 to March 3,	790	16,800
Beg. of orange-blossoms, Mar. 3-18,	2333	34,995
Full orange-blossoms, Mar. 18, Apr. 10,	2610	57,200
Beg. of no flowers, then cactus, Apr. 10 to May 21,	1000	40,000
Chaste-tree blossoms, May 21, June 17,	2111	56,997
Chaste-tree, then thyme, June 17, July 10,	2277	50,094
Thyme and end of it, July 10, Aug. 3,	1250	30,000
Thistles, Aug. 3-29,	460	10,960
Honey in the hive, Aug. 29, Sept. 13,	20	4,000
Peppermint and others, Sept. 13, Oct. 14,	115	3,000
Nothing outside, Oct. 14 to Nov. 11,	35	1,000
Nothing outside, Nov. 11 to Dec. 10,	28	1,000
Nothing outside, Dec. 10 to 31,	0	
		320,034

About the same at the end of the season as regards the number—20,000 bees. At all events, this gives us an average of 76 eggs a day for 365 days, or 1760 eggs a day if we take the honey-flow season from March 3 to August 3. The colony did not swarm, and at the end of the season it was reduced to very nearly what it was in the beginning; 300,000 bees were hatched, and passed away; the hive had produced nearly 180 lbs. of honey. This honey was taken by the extractor, April 10; April 18, orange-blossom honey; June 13 to 29, chaste-tree honey; July 10 to August 3, thyme honey.

Where the bees of a hive go to is, of course, to be attributed to divers accidents—visits, etc. The average bee's life during a honey-flow is

between 35 and 40 days; but this is only the average; for suppose we introduce 6000 eggs, newly laid, into a colony, mark well the difference, take blacks for yellows or yellows for blacks. After the 21 days required to hatch, and 40 days supposed to be a bee's life, you can hardly find a hundred—often less—in some hives. Even 35 days is the extreme limit. The few bees that remain are worn out, and can hardly be distinguished. Where they went to is: 1. Their work wearing them out; 2. Winds, rain, cool weather, overtaking them while far from their hives; 3. Birds, reptiles, insects, spiders, which lurk for them either at the entrance or in the air or on the flowers. The nearer a bee arrives to or passes the thirty, the easier it is caught or killed. It seems, of course, at first sight, that the number of these losses is too small; but it must always be remembered that it is the infinitely small that forms our doings, sayings, and surroundings.

Great streams from little waters flow;
Great oaks from little acorns grow.

I find very nearly the same figures as the foregoing given in a hive I observed this year at Nice and in the Alps; and I find the average of the honey money months, March 14 to August 3, 1857 per day—almost 100 eggs more here than in Palestine, without giving as much honey—not very from half the amount only. I extracted, too, May 19 to June 3, orange-blossom; July 13 to 27, and August 14, lavender.

Nice, France.

PREPARING FOR NEXT SEASON.

Question.—Having my bees all fixed for winter, I wish to know what I can best do during the coming winter months to be of the most advantage to me for next summer's operations with the bees.

Answer.—The apiarist who is to be successful has little time to waste; and I judge our questioner is made of the right material for a successful apiarist, for he wants to know what to do next. Right here I wish to say that, if any have started into the bee-business on the supposition that "bees work for nothing and board themselves," they had better get out of it, for no success can be obtained along that line. As soon as the bees are properly prepared for winter, which should be as early as November 15th to December 1st, we are ready to go to work for the next season, and so we commence operations at once, remembering the proverb of the ancient wise man who says in the "good Book," "Seest thou a man diligent in business? he shall stand before kings."

The first work is to get our wide frames, or cases, and sections which have been in use the past season, in readiness for the next harvest. Get them around, and scrape off all the propolis adhering to the tin separators and all the bits of comb, should there be any, fastened to the bottoms of the wide frames. All these bits of comb, as well as all others, should be saved; and to best save them the wax extractor should be close at hand, and all waste pieces of comb put into it during the whole season. As often as it is full, get out the wax and have it ready to fill again. All sections which are partly filled with honey should have the honey extracted from them (unless you think you will need it to feed in the spring), as the honey will not correspond in color or quality with that which the bees will put in to finish out the sections the next season. To extract this nicely, fix a shelf close to the ceiling of your room; put the honey thereon, and keep the room so warm that the mercury will stand at 90 to 100° for three or four hours before you commence to take the honey out. By placing the honey near the ceiling we do not need near the fire to heat it that would be required if placed on the floor or a bench. These partly filled sections, if extracted without warming, would all be ruined, so far as the combs are concerned, and the apiarist's prospects of a large yield of honey the coming season would be ruined also; for, according to my value, they are better than money in the bank. After the honey is extracted, these sections are to be put in the center wide frame for each hive, or, in other words, are to be used as "bait sections," which should always be placed in the center of the sections on top of the hive, so as to secure an early commencement of work by the bees in the sections, and so the full sections shall not all come off at once, which would cause the bees to be loath to enter a second lot. Fill the rest of the wide frames, or cases, with empty sections, each having a starter of *thin* foundation in it, or fill the sections with full sheets of foundation, as you prefer. Having all complete, pack them away where they will be ready for use, at a moment's notice, next June.

Our next work is to secure our material for further sections by buying or otherwise, and make it up. To arrive at the number I wish, I allow 150 one-pound sections for each old colony I expect to begin the season with, in the spring; and after 25 years of experience I find this estimate not far out of the way. It is well, always, to be sure and have enough, for it is far better to have a few sections left over than to find our sections exhausted in the midst of a good honey-flow. Many put off this getting-ready part till spring, so that they may know how the bees winter; but the one who expects to make a bee-keeper worthy of that name will not do this; for if the getting-ready part is put

off till just before the honey-harvest, the result almost always shows a greater or less loss.

Having the section part all in readiness, we next make what hives, frames, covers, etc., we think we shall wish for use the next season. Having these made, wire the frames and put in the brood foundation, so this part will be in readiness also, resting assured that the bees will work this foundation just as well when wanted as they would had it been put in the frames an hour before placing in the hive.

After having the frames thus prepared, place the number you wish to use in each hive, and pack all nicely away.

Then there are the shipping-crates for honey, to be gotten ready; shipping-cages for queens, if we raise queens for sale; and anything or every thing which we have planned by way of experiments which we wish to try in the near future, all of which, as far as possibly can be, should be prepared during the wintry days so that, when spring opens, we shall have nothing to do but to give our whole attention to the bees.

If you are to succeed in the bee-business you will prefer to do these things, and find pleasure in doing them, rather than idling the winter away waiting for spring to come to see "what will turn up" with the bees and your business. Above all else in importance is a thorough knowledge of apiculture; and the long winter evenings which are now here are just the time to gain that knowledge. Get around the back volumes of GLEANINGS and other bee-papers, if you have them; also, if you do not have them, procure one or two good books on bee culture, and read them thoroughly, so as to put what you learn in practice the next season, and thus you will have, in the majority of cases, an answer to what would be a puzzling question to you otherwise, in your own head, instead of having to go to some one else for an answer, just at the busiest season of the year. In these ways a person can be always advancing, instead of standing still or retrograding. Don't be found around the country store or saloon, winter evenings, sitting on dry-goods boxes and barrels, filling the minds of others, or allowing your own mind to be filled with idle gossip, and often worse than idle gossip, or spend your time over an old dingy checker-board, or a musty pack of cards. Perhaps some of these might do, if the hours hung heavy on our hands; but these things are not in place for an energetic, wide-awake bee-keeper with plenty of unread bee-literature at hand. If you are not enough interested in the study of bees to learn about them winter evenings, preferring the places and things above mentioned, to the study of bees, I can give you no assurance of success; but, on the contrary, shall be obliged to predict only a failure, as all of my knowledge of the business compels me to say

that in this, as in all other pursuits, success comes only to those who make some sacrifices to attain the desired end.

SIXTEEN pages extra this time, and 5000 extra copies, making 15,000 in all.

OWING to the space taken by the Langstroth memorial in this number we are obliged to leave out much of our regular matter.

As will be seen by the honey column elsewhere, honey is selling very low. The trouble is, bee-keepers are rushing their honey too much to the cities, meeting sharp competition.

REPORT of the bee-keepers' Congress at Atlanta will be found in the department of Travels by A. I. R. He reports a good meeting, and believes he has brought home from that convention a good deal of value.

MR. BALDENSPERGER, on page 951, gives an interesting table of the daily average of egg-laying by queens in Palestine. The smallest number was 100 per diem, and the largest 2600. While a queen *can* lay 3000 eggs in a day, she doesn't often do it.

MR. JAMES HEDDON, of Dowagiac, Mich., requests me to say that, owing to a bronchial trouble, caused largely by the "breathing in of the odor of the bees, and their poison," he has been obliged to suspend the publication of his paper, the *Bee-keepers' Quarterly*.

In this issue there is, perhaps, the most complete history of the movable frame in its various stages of development, up to the perfected frame of Langstroth, that was ever published in any one journal or book either. It is a significant fact that leading apiarians in Europe as well as America agree as to the great superiority of the frame given us by the father of American bee-keeping over others that preceded.

FOUR, and perhaps five, bee-journals (I can't quite keep track of the number) have died in America alone during the year just closing. The new year will help to fill up the gap by the arrival, on Jan. 1, of what will be known as *The Pacific Slope Bee Journal*. It is to be published by the Bennett Bee-hive Co., Los Angeles, Cal. Price is to be \$1.00 per year. We wish the new (ar)rival success and a happy new year. It seems to me there ought to be a good field for a bee-journal in the greatest honey section in the world; at all events, the

announcement says the new journal will "be here to stay."

OUR readers will notice by the last paragraph of the Rambler in this issue, that the series of Rambler articles is to be discontinued. I know that these articles have been appreciated, by the many expressions of approval that have come in from time to time. If still desired, perhaps some arrangement may be made whereby they may be again started, or something else in their place from the pen of the Rambler be substituted. I should be glad to receive expressions from our readers.

WHY BEES SPRING-DWINDLE

more in the cellar than outdoors (and I think it is generally conceded that they do) may perhaps be found in the very possible explanation put forth by R. McKnight, in this issue. It has generally been held that an unvarying temperature in the cellar was desirable. But here, perhaps, we have been making a mistake. Bees outdoors are surely not subject to a uniform temperature. With us it varies from 60 above to 10 below zero. A cold spell rarely lasts longer than three weeks. This is a timely and important question, and I hope it will be further discussed.

OUR CHRISTMAS NUMBER.

NEVER before, I think, has it been the lot or privilege of any bee-journal, certainly not of GLEANINGS, to publish in any number such a list of articles from such eminent bee-keepers and writers on bee-lore from all over the world as in this our Christmas issue. Representatives from seven different countries have spoken, and six of them have sounded the praises of Langstroth. Six different bee-editors—two of them ex-editors—have contributed to the Memorial. Besides the usual number of illustrations and other general matter, A. I. R. himself is actually writing on the subject of bees. See his department. There, there! I didn't mean to blow our own horn; but somehow it has been a real pleasure to me to think that we could suitably pay our respects to the memory of Langstroth. It is no little source of gratification that bee-keepers and bee-editors, without regard to country, have been so generous in their responses; and to our friends across the water I desire, in the name of the American bee-keepers, to express especial thanks.

THE CALIFORNIA BEE-RANCH, ON PAGE 941.

I CONFESS this picture brings a host of pleasing recollections to mind. On almost every bee-ranch in California the extracting-house is invariably located on high ground, usually near the roadway. The honey runs from the building through a pipe, into a huge can made of galvanized iron. Some of these cans are large enough to hold a ton or more. This can is also located sufficiently above the driveway, or

some wagon-road, so that the honey may be drawn from this large tank into barrels or cans that stand almost on a level with the bed of an ordinary wagon. In this way the honey is loaded up ready to be taken away without any heavy lifting at all. Where the hives are located on lower ground than the honey-house the combs are frequently run up to the honey-house door, on a suitable car, cart, or wheelbarrow. In the picture mentioned we get a glimpse of the apiary just a little above the honey-house. So you see it is downhill work from the time the honey is taken from the hive until it is ready to load. A. I. R.

DIFFERENCES OF OPINION ON HOFFMAN FRAMES AND HONEY-BOARDS.

FRIEND Hutchinson can't understand how such "bright practical men" as his Medina friends could adopt the Hoffman frames. I suspect it is all because he hasn't tried them—at least, as we have. But, say! I can't see how such a bright practical man as my Flint friend can use and like the old honey-board with all its attendant burr-comb attachments. With our Hoffman frames we are practically free from the trouble. Clearly, here are differences of opinion; but they are, I am sure, honest differences.

I am willing to admit, however, that there are those whose ways of working have been such that they could not like the Hoffman, and for that reason we give our friends the choice of several styles—one reversible, one loose unspaced thick top, and one old-style Langstroth, pure and simple, with top-bar $\frac{3}{8}$ inch wide and $\frac{3}{8}$ inch thick. This last requires a honey-board, which we also sell, for those who want it. We may also, for those who may prefer, add to the list a thick-top frame with some form of metallic spacer—a Stephens or some form of furniture-nail spacer.

I tell you, friends, we can't all like the same things or all see things alike.

FEEDING BACK; WHEN IT DOES AND DOESN'T PAY.

ON page 856 we published an article from Doolittle that seemed to show that feeding back didn't pay. While I think that, as a general rule, it is not profitable, I do not wish to overlook the cases where it apparently is so. In a recent article in the *Progressive Bee-keeper*, it seems to be shown that it can be made a success; but friend Flanagan says, in summing up, "If one has time on his hands, and plenty of drawn sections, . . . and plenty of cheap extracted honey, it may pay; otherwise, *decidedly not*." Bro. Hutchinson, in commenting upon this article in his own paper, says:

But very little profit can be made in "feeding back" unless there are partly finished sections as a foundation. Sections filled with undrawn foundation won't answer. I can't explain why; I simply

know that too large a proportion of extracted honey is required as compared with the amount needed when partly finished sections are used. With plenty of these on hand, and the right kind of bees, feeders, and weather, there is no question but what "feeding back" may be followed with pleasure and profit.

First comes the selection of colonies. Blacks are first choice, with hybrids a close second; next come dark Italians. No great success can be made with light-colored bees. The brood-nest must be contracted to not more than five L. frames, and better results are secured if only three frames are left in the brood-nest; but the strength of the colony is likely to suffer if contraction is carried to this extent and very long continued.

THE WEIGHT OF BEES AND BEE-LOADS; THE PRACTICAL SIDE TO THIS AND OTHER SUCH QUESTIONS.

THE editor of the *Review*, while admitting that it may be interesting in a scientific way to know the exact weight of a bee and the amount of nectar it can carry at a load, fails to see any practical benefit to the honey-producer. If our printed matter were to be confined simply to the methods for converting the labor of our minds and hands into bread and butter, and honey to put on it, some of the best literature of our bee-journals would have to be eliminated.* Man does not live by bread alone, neither should he try to. The practical bearing on some questions is not always at once apparent.

In the case of the bee's weight, or the weight of honey it can carry, there is a practical side. The knowledge of the average bee-load of nectar gives us the key to the solution of the problem of the number of bees necessary to carry a pound of nectar, and the number of trips that have to be made to the fields. Indirectly we learn how many workers a colony should have in order to get the best results from a certain honey-flow. But perhaps friend Hutchinson would ask, "How about the weight of a bee?" In order to know the weight of a bee-load we must know the weight of the bee itself.

Then, too, there have in times past been all sorts of rude guesses as to how many bees there were in a ten-frame colony. Our knowledge is now much more exact; and hence, in discussing practical questions—those that involve bread-and-butter-getting—our comparisons and our statements of bee forces will be more in keeping with the facts, and hence lead to more exact results.

BEE-JOURNALS AND THE SUPPLY BUSINESS.

Various comment has been offered in some of the bee-journals as to whether the *American Bee Journal* is harnessed to the supply-business or under the wing of GLEANINGS now that its editor, Mr. York, has been engaged to manage

*The Langstroth memorial in this issue, for example, does not have much of practical value to the honey-producer, but it does greatly enrich our bee literature.—Ed.

the Chicago office of The A. I. Root Co. So far as the *American Bee Journal* is concerned, it is just as independent as before. It has no connection, pecuniarily or otherwise, with GLEANINGS or its publishers. As Mr. York was an old wheel-horse in the supply-business under Thos. G. Newman & Son, and as the successor of that firm had sold out its business to us, Mr. York, by virtue of his experience and general acquaintance with the territory, was engaged to manage the Chicago branch office; and warehouse rent, insurance, cartage, freight, and stationery, etc., are paid by us. But suppose the publisher of the *American Bee Journal* did open up a supply-office, the same owned and controlled by himself; would that necessarily weaken the influence of his paper? If he were selfish, and inclined to "boom his supplies" irrespective of their merits, through his journal, he would hurt it; but he is not disposed to do any thing of that kind.

Mr. Hutchinson, in writing upon the subject of journals and the supply-business, says that he doesn't know that "there is any thing especially praiseworthy in an editor keeping out of the supply-business;" that "the selling of supplies allows the dealer to publish a journal at a lower price;" that "most of our bee-keeping editors, if not all of them, are pretty fair in allowing competing goods to be described in their journals," and that "there are no bee-journals that can be called 'house organs.'" Friend H. closes up in this way: "I must admit that my views regarding a publisher also being a dealer have been somewhat modified since I have been able to look at the subject from a publisher's standpoint." These statements, coming as they do from one who publishes a journal practically independent from the supply-business, are, to say the least, kind and fair toward those who conduct the two together. Surely it would be no very sad thing if Bro. York should have even a financial interest in the supplies. So far as GLEANINGS is concerned I am sure I have tried to give our competitors a chance in our Trade Notes department to show their goods. Often, too, I have taken the pains to call for articles that rather "sat down" on our goods, and, as some might call them, on my pet notions. A journal, to be a journal at all, must let all sides have a fair hearing.

THE NEW WEED PROCESS OF SHEETING WAX FOR FOUNDATION-MAKING.

THIS is proving to be a great success. Yes, the new machine feeds a continuous sheet of wax, any thickness, from between a set of dies or parallel bars to any desired length—a mile long—without stopping, if need be. In practice, however, the wax is rolled up upon bobbins holding about 25 lbs. These bobbins are then set in a set of bearings (in a vat of warm water), just back of the foundation-machine. The

free end of the sheet is fed into the rolls, and, presto! the whole bobbin of sheeted wax can be reeled off without stopping the mill. In practice, however, again, the foundation-mill reels off a length, and stops where the sheet is cut off. A pressure of the foot applies the power, starts the mill, and more is reeled off, and cut to the desired length. We have our plans laid, however, to run the wax through the mill, the whole 25 lbs., without stopping. An automatic cutting-off device will then in the mean time cut the sheets up into the required lengths.

This is not all. A new and better product is secured. The wax, besides being of an absolutely even thickness, is much more beautiful and transparent. Indeed, some of it, even before it is milled, looks almost as transparent and beautiful as rock candy. Nor is this all—it is tougher and yet more pliable.

It may be well to state to those not familiar with foundation-making that the old process of sheeting involved dipping a strip of wood one or more times into a deep vessel of hot wax. The adhering film, after being dipped in water to cool, was then stripped off. Besides this labor of sheeting in short lengths, there was the labor of starting the sheet into the mill, stopping it to pick off the end from the rolls, and starting again until rolled out. This process had to be gone over again with each sheet.

It will be seen that the new Weed process effects a great saving of labor. There are no more short-length sheets, no back-breaking process of dipping, no starting and stopping the foundation-mills at frequent intervals, and no picking and picking to get the sheet off the roll.

The new machine runs almost alone now; but an attendant stays by to operate, occasionally, the valves to regulate the flow of wax and the cooling process.

Mr. E. B. Weed, formerly of Detroit, later of Brantford, Can., and now of Medina, is the inventor. Patents are now pending, and I sincerely hope Mr. W. will be rewarded for his pains. For two or three years he has been working and experimenting, with much discouragement. Every one gave it up but he and Holtermann. They knew he was on the right track, but couldn't make a practical success of it. They finally succeeded in overcoming the last obstacle. But the machine was not a success; it was too light, and too every thing in spots. Our Mr. Washburn, the man who first made the roller comb-mills, at once appreciated the weaknesses of the machine Mr. Weed brought from Canada. To make a long story short, drawings were made, patterns gotten out, and in a short time a new and stronger machine was built, with results as above stated.

OUR HOMES.

He shall call upon me, and I will answer him: I will be with him in trouble.—PSALM 91:15.

Thanksgiving day was bright and warm. It afforded an excellent opportunity for some outdoor work that very much needed to be done. Let me explain. Three years ago I described our little greenhouse across the way. I have told you in detail of the strange blundering way in which I made the discovery that greenhouses could be warmed automatically by means of exhaust steam. In my first experiments I was so much afraid the thing would not work that I picked up pieces of old rusty iron pipe, hastily put them together, and pushed them up through the tiles. Somewhat to my surprise, and much to my delight, the thing worked beautifully. Summer and winter, month after month and year after year, the hot water went its rounds, giving out its heat overhead in the greenhouse, and then going back to the point of starting, to be warmed up again. Last winter, however, while I was in Florida the circulation gradually slackened up, and during the most severe weather the pipes cooled down in spite of every thing that Ernest and the boys could do. They were cold when it was most important that they should be hot.

It was so late in the season when I returned, that we managed to get along with our stuff. When I went at it this fall to straighten the thing out, the difficulty seemed to be somewhat obscure; so the matter was neglected until Thanksgiving day. On that day, with the help of Frank, one of my faithful boys, I decided to *locate* the mischief, at any rate. Instead of being in the greenhouse, it proved to be somewhere in the *underground* line of pipe that the obstruction lay. Now, this line of pipe is not only about two feet under ground, but it also runs through a six-inch tile. We could dig down to the tile, but we could not lift out a length without breaking it, because the iron pipe is in the way. Frank and I made excavations in different places on Thanksgiving afternoon, but did not succeed in locating the trouble at any exact point.

The little pipe I used to make my first experiment with was only $\frac{3}{4}$ inch in diameter; but it worked so nicely there that it had stood doing its work all these years. One thing I decided on Thanksgiving night was that I would nevermore use *old* pipe to put under ground; and I also would never *again* be guilty of using pipe as *small* as $\frac{3}{4}$ inch. One inch is small enough and cheap enough; but $1\frac{1}{4}$ would be better.

On Monday morning I was to go to Atlanta, so there were only two days left—Friday and Saturday—and these two days the last of November were very apt to be stormy and cold. During the night I thought over all the things that were to be done the next day. First, these hot-water pipes were to be fixed before the weather became any colder. Some additional radiators were to be put in at the house also. Some more copy was to be furnished for GLEANINGS, and this was to be out so it could reach the friends around Atlanta, before the convention of Dec. 4 and 5. Other matters were crowding in various parts of the factory.

Friday morning proved to be all that could be wished, so far as *weather* was concerned, and I fairly trembled to think of the number of things I was to look after before I took my trip to the South. By some of my own bungling, there was no meat ready for breakfast; and when a boy went to the meat-market he had to wait nearly half an hour for them to open up shop. The boy who makes it a business to feed

the horses so as to have them ready to hitch up when the whistle blows, also failed to come around. Perhaps it was because it was just after Thanksgiving. The assistant engineer had hurt his finger a day or two before, and the engineer wanted Harold (the young plumber whom I have mentioned before) to *fire* for him. He thought no one else would answer.

Breakfast was finally ready, and had to be eaten just as my men ought to have been getting their orders for the day. It was hard work to obey the doctor's orders to take plenty of *time* for my meals. Then it was a task once more to get the family together after a late breakfast, for morning prayers. Satan whispered that, under existing circumstances, family prayers would better be omitted for just once. As I have never listened to Satan, however, especially when I wanted advice in *such* matters, his suggestion did not amount to very much.

When I got over to the factory, somebody had promised that Harold should do some plumbing for a neighbor; then another man who was hurrying *his* job of piping could not be waited on because half a carload of New Queen potatoes had been hastily piled in the cellar on top of the iron pipes he was waiting for.

Frank and Fred had got the iron pipes apart, and were pushing a wire down through them as far as it could go, to start the accumulations of rust and scale; but the water could not be made to go through, even under pressure. The boys were doing the best they could; but they needed more pressure, and every thing seemed to need more *brains* all around—perhaps brains of mature experience. I called a man who had done such work, and directed him to attach a Whitman fountain pump to the end of the iron pipe, and *force* the water through. Somebody had borrowed the pump. When it was hunted up, the valves would not work. I finally decided that we should have to take a brand-new \$6.00 pump from the stock in the store out there into the dirt and water. But there were not any *new* pumps—the stock had been sold out. The clerks told me they had another kind that was better, but it could not be attached to our iron piping—that is, without too much time and expense.

At this juncture the plumbers over at the house were hindered in their job by lack of some special fittings. The train that was to bring them did not bring any thing. The printers were wanting my last Special Notices, so the form could go to press. I was already overburdened with cares; the beautiful warm forenoon was passing away, and my heart had not been cheered by *success*—that is, very much success—in *any* direction. The helpers were all doing their duty; but wherever I was boss it devolved upon me to say what should be done at this unexpected crisis.

Surely there were burdens enough that forenoon for Thanksgiving day. But it seemed that a still harder one to bear was coming. One whom I had been instrumental in bringing to Christ Jesus was backsliding. The backsliding had got to a point where I must stop right then and there, and decide what was to be done. From what I have written in these Home Papers, and from what you know of me, very likely you will wonder where my faith and trust in an overruling Power were at such a time. Well, I am afraid I had been too busy to ever think of asking for God's help. I am afraid that I had a sort of idea, when I got up in the morning, that I could manage without his help. You see, I am older than I used to be, and am feeling quite strong and well, and I

have had "lots of experiences." But on this particular morning *all* my plans and projects seemed to be failures. I had undertaken things I could not get through with. Saddest of all, I had undertaken to lift a soul out of the miry clay on to the clean strong rock of a faith in Christ Jesus, and *he* was a failure too.

This last burden—no, it did not break me down, but it brought me to my senses. A very earnest and fervent "Lord, help!" welled up from my heart; but I confess that it was without very much faith. Then when I looked at the boys, with their muddy hands and clothing, so willing and patient in doing any thing I wanted done, another "Lord, help!" welled up from my heart; but that, too, I am afraid, was without very much faith. Then I remembered the surgical operation at Battle Creek, and that little couplet from the hymn,

I am weak, but thou art mighty.

Yes, I felt myself *decidedly* weak. I let some of the things go, and walked over to the boys. In a few minutes they had met with success on one of the lines of pipe. The hard water from the windmill tank, that had been coursing through even the galvanized-iron tubing for many months, had deposited an incrustation of chemicals or lime at the lowest point. With a heavy wire and a strong force of water we succeeded in rasping the limy deposit loose so it could be washed out. The missing fittings had been found at one of the shops up town, so the plumbers at the house could go on; while Mr. Warner, with a big stout German and a boy to help, had moved the potatoes, and our customer had his iron pipe.

I began to think that one little earnest fervent prayer was moving things mightily; but an interview with the one who had got back into the miry clay made me feel that it is a far greater and oftentimes more *wearing* and *discouraging* work to try to save a sinner from the error of his ways than to get the obstructions out of a crooked iron pipe that is two feet under ground, inside of stone tiles, and running under various beds of garden-plants besides. Müller once said that it is a much easier matter to get *money* by praying than to *save souls* by praying—especially where Satan had got a strong hold on the lost one.

The battle was not won yet, by any means. More earnest prayer was needed; more lessons were to be learned in regard to my need of divine help. I thanked God for the success we had made, acknowledged my own feeble helplessness, and plead again with perhaps greater faith. It looked for a time as if our pipes would have to be all buried up again until I could get back from Atlanta, without having accomplished any thing. I could not bear the thought of this; and yet if I should go to tearing up things much more than I had already done, nobody could put them back in shape in the brief time that was left. The weather-telegram announced a coming storm and colder weather. We had narrowed the stoppage in the pipes down to the lowest point in the piping, and it was not more than 20 feet in length; but the pipe passed right under three or four different beds of plants. The boys had pushed wires in from both ways, and had given up. I asked them to try it once more. Pretty soon a little muddy water came out; then still more; and finally a more slender wire was crowded clear up to the elbow, even though the pipe was crooked. The water came faster, and more muddy, and finally out it shot under full head, sending the pure sparkling liquid out many feet, carrying with it, now and then, lumps of sediment and deposit. The pipe was *clean*. It is now all covered up, and the greenhouse is

warm. My Thoroughbred potatoes and other plants are safe.

The spiritual work, however, that I had been trying to do, and which was, of course, of *many times* more moment than the water-pipes, did not prosper so well. Satan was too much for me. His victim had turned back on his best friends. He declared they were all trying to "beat him," and that they had a *spite* against him. Dear friends, have you not noticed again and again how the *real* sinner or the *real* criminal insists that, while *he* is honest and true, everybody else is vicious and bad? He will have it that all good people are trying to injure him; that his best friends have a "spite" against him.

Slowly and sorrowfully I was obliged to give it up. When I thought of the way in which business had been finally pushed along through the day, I felt to "rejoice and be glad;" but when I thought of this other, I felt sick at heart. I felt humbled—yes, a good deal humbled. Perhaps my sad and sorrowful tones may have had some influence on what I said. I spoke very kindly and gently, but I talked very plainly for all that. There was more inward praying that came from a very humble, and, I fear, a good deal discouraged heart. What do you think happened? Why, before I went to bed that night I was cheered by hearing a full and humble acknowledgement of the fault, accompanied by restitution *in full*. It was like the muddy deposit in the crooked pipe. It came little by little; and when the full, frank, and clear confession came out, accepting all the blame himself, and exonerating all of his friends, then I could see the light of the Savior's love shining down once more into the darkened soul—not darkened now, thank God, but full of light and peace, for the dark evil thoughts had been washed out. Satan had lost his hold. The prince of darkness had been banished entirely, and it seemed as if I could almost hear the Master say, "Go thy way, and sin no more."

But the whole matter was not to be allowed to be dropped just then and there. There is a part of that wonderful prayer that reads, "Lead me not into temptation, but deliver me from evil;" and before I started on my trip to Atlanta, several good strong posts of advance guard were put up to keep temptation away; and careful, faithful sentinels have been stationed, not only to guard against any surprise at some future time, but to *cut off*, so far as may be, the avenues where evil may be most likely to again come in.

ON THE WAY TO ATLANTA.

Does tobacco make a man selfish? As we got aboard for Cincinnati the cars were so full that one of our party remarked we had better pay a dollar more and take a chair car, where there was plenty of room; but we concluded to look a little first. I saw a man filling a seat with his valises, overcoat, umbrella, etc., and politely inquired if he could not let me sit with him.

"Why, I *suppose* so; but why don't you sit with some one else? there are plenty more places."

As I always dislike being where I am not wanted, even if I have a right there, I turned to a man across the aisle: "Why, certainly, and you are quite welcome," was the pleasant and

ready response; so I sat down. It was soon evident, however, that No. 1 did not intend to occupy the seat *himself* at all; for as soon as he had filled the seat he went into the smoking-car. Now, I always prefer a seat next to the window, and I therefore very soon moved the baggage, etc., to half of the unoccupied seat. In due time the owner of the stuff returned. I said to him:

"If you prefer a seat next the window, I will take the other; as you took the seat first, you surely should have first choice."

He looked at me a moment, then, evidently having no more of a fancy to sit by me than I had to sit by him (perfumed with his tobacco smoke as he was) he remarked, "I reckon I had better go back and ride in the smoker," and I saw no more of him until he came for his baggage when at his destination. I afterward noticed vacant seats all over the car. People usually kept out of them because they contained baggage, while the owner paid for one seat and used two. Well, if the railroad folks prefer to run a smoking-car for accommodation, it is all right, *certainly*; but I wonder if it has occurred to them that, while they do so much gratuitously for *tobacco-users*, they might certainly do a little in the same line for those who *ride wheels*. Do more people use tobacco than ride wheels? We shall soon see. Which is of more real importance to a man—his wheel or his—"smoke"?*

As we get down into Georgia and into the region around Atlanta I notice the ground on the hillside is almost all terraced; or the rows of corn, cotton, sugar-cane, etc., are planted so the furrows all run around the hills, exactly on the plan given in our tomato-book.

It is interesting to note that friend Day's plan is being carried out so generally. Where the best crops are grown, the whole plan in detail is fully carried out; and when it is so done, there is next to no washing, and no gully-ing at all.

Our trip to Atlanta was a very pleasant one. The railroad officials were pleasant and obliging; and although the weather was quite severe, even through the Southern States, we suffered no inconvenience at all in traveling. By taking some rations of beefsteak along, nicely cooked by Mrs. Root, I managed to have my meals regularly, and of the right kind. The hot water was easily managed by taking along a tin canteen. This, when filled with good water, was kept hot on the steam-pipes; or where there was a hot-water boiler on the car the porter kindly permitted me to place my canteen where it would keep hot and out of his way. I find it better to speak to the porter before taking liberties with his heating-apparatus, for he does not like to have passengers meddling with his department without permission. A little explanation and courtesy always secured all the privileges that I needed in this line.

As I have several times described the country between Cincinnati and Nashville, I need not go over it again. You will notice by the map that at Nashville we start out eastward toward

Chattanooga, and thence on toward Atlanta. Theride through the mountains affords a grand study to any one who is a lover of nature. It is always exceedingly interesting to me to look over the problems that were surmounted in building a railroad through such mountainous country. Usually they follow streams; or, as they would say in California, up one canyon, to the summit, and down another on the opposite side. Through Tennessee and Georgia a good deal of the road had to be cut *through* the hills more or less. The road curves around the hillside, first on the side of one hill then on the other, occasionally getting through by cuts so deep you can hardly see the top as you look out of the car window; and where the hills are very high, and the expense will warrant it, a tunnel is cut right straight through. The scene is occasionally varied by beautiful fertile valleys, along the side of clear rivers. A good deal of the land is, of course, unreclaimed and unused. The valleys, however, are mostly under pretty good cultivation, and in many places the ground is cleared and under cultivation, up almost to the summits of some of the mountains, on hillsides where you would think it was almost impossible to do any farming profitably. Some of this high land, however, is very valuable, so I am told, for certain crops.

Apples of great beauty, and of about the finest coloring I ever saw anywhere, are raised all through Georgia. At one station Mr. Calvert informed me they sold ten large beautiful apples for only a nickel; and the whole carload of people seemed to be eating apples in a way that I hope did them all good—at least, it did me good to look on; but I had some fears that at least a part of the crowd could not stand so many of them at all hours of the day; and before we got through, even Mr. Calvert, with his strong and rugged constitution, was obliged to admit that it would have been better had he eaten fewer, or taken them at regular meal-time.

Through Georgia they prepare the ground and sow oats all through the month of December. They were not doing it when we made our trip, however, for the ground was frozen hard, even in the middle of a sunshiny day. One of the passengers informed me that oats were very seldom injured during average winters. I made inquiries in regard to winter oats. He said they had tried them more or less, but the common variety seemed to suit their locality best. The prevailing crop, however seemed to be cotton; and I am told they raise cotton year after year right on the same ground, using little or no fertilizer except cotton-seed meal and the stalks, etc., left after the cotton. The cotton-fields, as a rule, are remarkably clean, and free from weeds; but judging from the size of the stalks, a good deal of the farming, like that here in the North, is not by any means what we would call high-pressure farming.

Perhaps the greatest foe to agriculture, especially on the hilly or uneven ground, is the washing and gully-ing; and I was greatly pleased to note that, all through the South, the remedy proposed in the back part of our tomato-book is the one in common vogue—running the furrows around the hills instead of straight across the fields. This is some trouble; but if it is done right, it seems to be a perfect remedy for washing. The Department of Agriculture, Washington, has put out a very interesting bulletin (No. 20), entitled "Washing Soils; how to Prevent and Reclaim them." The teaching is almost in line with that given by friend Day.

Atlanta is a very beautiful city of about 100,000 inhabitants. The streets are filled with

*The following newspaper clipping comes in very well right here:

The bicycle has proven a beneficent apostle for reform in more ways than one. If the assertion of the United States *Tobacco Journal* may be accepted, which declares that the bicycle has caused a reduction for the last year of seven hundred millions in the consumption of cigars, the reason assigned being that men seldom smoke while riding a wheel. It has doubtless caused, also, a large falling-off in doctor's fees, and left the patient who rode it in far better condition than if he had swallowed the whole contents of an ordinary drugstore.

people; large manufactories of different kinds are running in full blast, presenting a scene of activity and industry much like our progressive and growing northern cities. We found accommodation at Hotel Jackson at 75 cts. per day for room and bed, as given on page 901.

This includes electric lights and steam radiators, even clear up into the fifth story, where we found accommodations. An electric elevator is running constantly to carry people and baggage up and down.

This was a special arrangement (75 cts. a day), however, made for bee-keepers, with the understanding that they "double up." This means that you occupy a bed in a room where there are several bees. If the house is crowded you are to share your bed with somebody else. Our room contained three beds, and part of the time six occupants. Of course, they were not all bee-keepers, but we managed to get acquainted so that we had a very pleasant and social time. Meals are given on the European plan, and you can have a plate of toast for five cents, and a cup of tea or coffee for five cents each, besides various other five-cent articles, if you wish to be economical. You can also order a meal that will cost a dollar or more, if you feel inclined that way; or you can economize by carrying a lunch-basket, and sit down at a table, and order only a cup of coffee. I confess I like this plan very much indeed. For 40 cents I got a good sirloin steak, nicely cooked, with very little delay; and with the zwieback that I brought with me from home I had just what I wanted, and no more, at regular hours, without a bit of trouble. There are various places in Atlanta where you can get very good meals for 25 cents; a fair one for 15 cents; and there are even places where you are invited to come in and try their *ten cent* meals. We did not try any of the latter, but were assured that many kinds of good wholesome food could be procured, nicely cooked, at this low figure. I have taken this pains to particularize, because reports have been circulated that one could not get along at the exposition without paying 50 cents or a dollar for meals.

While I am on the subject, perhaps I should mention that we had a very nice dinner on the exposition grounds, for 50 cents each, at the Georgia barbecue. My first question was, whether I could get a dinner all of meat if I wanted to. The waiter rather smiled at my query, and said he guessed they could hit my wants to a dot. Then he brought in a huge platter of mutton, roasted barbecue fashion, that made me feel at once that I should not go hungry. After dinner I was invited to see how they cooked things at a barbecue. Several long trenches were made along a side-hill—that is, they were on a slant. These were filled with firewood, which was kept burning until the earth, bottom, and sides, were as hot as a brick oven. Then the various animals were slaughtered, cut into quarters or huge chunks, and through each quarter or chunk two iron rods were thrust, these rods reaching from one side of the pit to the other. Before the meat was put on, however, the fuel was all removed, except a bed of glowing coals in the bottom. The meat is then turned over on the iron rods, and given sufficient time to become thoroughly cooked all through. I can hardly explain why; but meat cooked in this manner, close to the hot earth, has a peculiar rich flavor. With the meat are served potatoes and other vegetables, and a sort of soup made of tomatoes, green corn, and other vegetables. If I am correct, the food is all cooked in these earth trenches. It makes one think of the Bible stories of olden time, where hundreds or thousands of domestic

animals were roasted at a single feast; and the barbecue idea certainly seems calculated to encourage the consumption of more meat and less of other things.

Harper's Weekly describes the stew, or soup, by the following graphic account of how it is made, from one of the colored cooks:

"Well, yer see, yer jest takes de meat, de hog's haid, an' de libbers, an' all sorts er little nice parts; an' yer chops it up wid corn an' permattuses, an' injuns an' green peppers, an' yer stews an' stews till hit all gits erlike, an' yer kain't tell what hit's made uv."

They add:

"It is a necessary adjunct of the dinner; and when it is made sufficiently hot by a sufficient quantity of pungent peppers, it is indeed a rare appetizer."

THE ATLANTA BEE-KEEPERS' CONGRESS.

The gathering of bee-keepers was not large, probably owing to the severe weather; but what we lacked in numbers we made up in quality, for we had some of the best honey-producers present to be found in America, and perhaps some of the best and most successful on the face of the earth. I was much gratified to meet so many of the good friends who entertained me so well while in Florida last winter—W. S. Hart, O. O. Poppleton, A. F. Brown, and Wm. P. Wilkinson. Mrs. Harrison came in the second day; and our veteran friend, Mr. C. VanDeusen, of Sprout Brook, N. Y. (proprietor of the wired flat-bottom comb foundation), was present during the whole session. Friend V. is now 81 years old, and came to the convention quite unattended. He looks quite hale and hearty, and one would hardly suppose by his looks that he was really so old. Like myself, he ordered *hot water* instead of either tea or coffee; and perhaps this may give us a suggestion as to the reason why he holds out so well. I noticed, also, that both himself and Mrs. Harrison were choosing mostly the lean-meat diet as I did. Our friend J. D. Fooshe and wife were also in attendance. Friend F. is getting to be a veteran in queen-rearing, as you may remember from his advertisements.* Dr. J. P. H. Brown, also one of the old wheel-horses in bee culture, seemed to be the prime mover of the whole affair.

Discussion was opened by a paper from Mr. Charles Dadant, in regard to why bees swarm. Friend Hart told us he had managed his large apiary for several years past with so little annoyance from natural swarming that it did not amount to more than three or four swarms from a hundred colonies on the average. His principal remedy (together with the proper shade from the great scuppernon grapevines), is to take the honey out of their way, and give both queen and bees plenty of room. You will remember he uses a large solar evaporator for ripening his honey. This enables him to remove it when only a very little of it is capped over.

Some discussion resulted as to whether honey ripened by the sun was fully equal to that ripened in the hives. Friend Hart gave us pretty conclusive evidence that his product was certainly not *very* much behind that of other bee-keepers. Friend Poppleton thought the same result could be accomplished by hav-

*Friend Fooshe has a contract to furnish Buist, the great seedman, with 22,000 lbs. of seven-top turnip seed. The plants are now growing on 32 acres; and when they come into bloom all at once it ought to make a boom for a pretty large apiary, and then we can tell what honey is like, gathered from seven-top turnip. Providence permitting, I may visit his place when the honey-yield is at its height.

ing large hives, or the "Long Idea," as it has often been called, of spreading combs out horizontally, so as to give the bees ample room. This would prevent the necessity of such frequent extracting.

Considerable discussion followed in regard to the nameless bee-disease, or bee-paralysis. Friend Poppleton thought he had lost tons of honey by the damage resulting from that disease. The general testimony seemed to be that no remedy yet proposed hit all cases. Quite a number thought it was worse with Italians than with the common black bees. I asked if we had a queen-breeder in America who could furnish us full-blooded black queens at a low price.

Pretty strong evidence was brought forward to show that neither bee-paralysis nor foul brood is ever carried from one place to another by buying and selling queens. Of course, if the feed sent with the queen contains honey from foul-broody hives, it might spread the contagion; but the queen herself, and the attendant bees, with ordinary care, need never spread either of these diseases.

A bee-keeper near Atlanta, Ga., reported 700 lbs. of honey from cotton, during one season, from 30 colonies; but the cotton-plant yields honey only occasionally.

WAXING BARRELS, ETC.

On page 899 we read, "A barrel or keg properly made of the right kind of wood needs no waxing." I confess I felt uneasy when I first saw it. The question came up in our congress, and both Mr. Hart and Mr. Poppleton, and all the Florida bee-keepers, declare that every barrel must be well waxed or paraffined. Friend Poppleton suggested that honey that ordinarily soaks into the wood would alone pay the expense of waxing. The waxing process is the quickest method of ascertaining beyond question whether the barrel is absolutely tight. Only about a pound of paraffine, costing 15 cts., is required if the waxing is properly done. First, the barrel must be not only thoroughly seasoned, but it must be made hot, either in the sun or by some method of artificial heat. When hot, the hoops should be driven down tight, and fastened. To prevent wax sticking on the outside, friend Hart puts the plug in one of the heads; and, before pouring in the wax, the outside of the head is dampened to prevent sticking. Pour in a sufficient quantity of melted wax or paraffine, and have it hot enough so it will not be cooled off very much in the process. As soon as you get the required quantity into the barrel drive in your plug. The hot wax will expand the air in the barrel so as to make a tremendous pressure; and when you come to roll the barrel over, and twirl it around so as to cover the whole inside, if there is any crack or cranny anywhere the wax will be forced out at this spot. If your barrel is hot enough and dry enough, the wax will never cleave off on the inside. In Florida there is a minute insect that makes small pin-holes in barrels and other utensils; and the only protection from leakage is waxing just before the barrel is used. Cypress wood makes a more perfect and a lighter barrel than any other material. Barrels made of oak, unless thoroughly waxed, will give the honey a taint that may spoil its value, or cut it down considerably. Let us remember that our Florida friends have had much experience in all these matters, for they marketed over 40 tons of honey in 1894, and all from one comparatively small locality.

THROWING OUT THE BROOD WHILE EXTRACTING.

Unless you have a very careful operator a

good deal of the brood is likely to be thrown out with the honey; but this is much more likely to be the case where the small extractors, made only for the L. frame, are used. Large extractors, like the reversible Cowan, and others, are much less liable to do this; but Mr. Poppleton thinks he could throw out the thickest and most thoroughly ripened honey with one of these large extractors, without disturbing the brood at all.

Our irrepresible friend Danzenbaker was present, of course; and it is really worth something to listen to his animated talk about his new hive, and especially his one-pound section, made 5 inches tall, $3\frac{3}{4}$ wide by $1\frac{1}{2}$ thick. This section has been used for several years past by Capt. J. E. Hetherington. Friend Danzenbaker has a long string of arguments to prove the great advantages of this section over the square one. The principal one of these points is, however, to my mind, that, being taller and thinner, it permits of placing 32 sections on top of the hive, where with the ordinary one-pound section we have room for only 24. He claims that the bees enter them more readily because they are deeper up and down, which may be true; and very likely (as there is more surface for attaching it to the wood), it may be a little stronger for bearing shipment. The idea, however, that purchasers at large will pay more for honey in sections of this shape seems to me a little strange, aside from the fact that it is something new and a little different from the ordinary style. It may be, however, that a section of honey something the shape of a testament or hymn-book looks a little better to the general eye than one exactly square. Permit me to say to friend Danzenbaker, and hundreds of others who are getting out new inventions, and especially those who have something new to offer every New Year's day (or oftener still), that it will cost the bee-keepers of the world something like a million of dollars to change the dimensions of their frames and section boxes in common use. At one time in my life I was persuaded that the Langstroth frame was not the best-shaped one, I accordingly adopted what I called the "Standard frame," and urged everybody to go into it, changing their hives and fixtures all over. At that time I had influence enough to induce hundreds of bee-keepers to commence changing their hives. After three or four years, however, I was so sure that I had made a mistake I went back again to the old established Langstroth, and tried to drag all the rest, who had been foolish enough to follow me, back to where we were in the first place. The Standard frame is now almost unknown, and we are fast getting to a point where the L. frame is the principal one in use everywhere—north, east, south, and west. If a general change is ever made, it must, in my opinion, be for *better* reasons than any that have as yet been brought forward.

HONEY THAT NEVER CANDIES.

Several bee-keepers from the vicinity of Atlanta astonished us by declaring that their honey *never* candied. One man said he had never seen any candied honey until he saw specimens on the table before the convention. On being interviewed we found his honey was secured from various sources. Now, it is very peculiar that honey from a certain locality never candies, no matter what the bees work on. There were others present, living not very far away, who mentioned having certain kinds of honey that would candy hard and solid, even when stored in sections, and capped over.

The general account of my visit to the exposition grounds will be given in our next issue.

Special Notices in the Line of Gardening, Etc.

By A. I. Root.

WANTED, SEED OF THE CHAPMAN HONEY-PLANT.

Can any of our readers furnish us some of the above? Every little while it is called for; but we are out, and do not know where to get more. If you have any to offer, please mail us a sample, tell us how much you have, and what you want for it.

OUR NEW SEED CATALOG FOR 1896.

All those who would like our Seed and Plant Catalog mailed them regularly whenever we get out a new one will please tell us so on a postal card, or please be careful to mention it whenever you are writing us on any other matter. We are just now making out a new list of the names of our customers in this department.

SHELLBARK HICKORYNUTS.

Medina County is not only celebrated for its maple-trees, but for its "shellbark" hickories as well. This season there is a great quantity of fine nuts. We have just secured a nice lot which we can furnish at the following very low prices: Quart, 5c; peck, 25c; half bushel, 40c; bushel, 75c. You can have these included with your express and freight order at the above figures. Sample by mail 5c, if you would like to see them before ordering. In localities where they do not grow they are often quite a treat to the children.

A CHRISTMAS PRESENT FOR YOUR WIFE.

A beautiful cloth-bound book—title, "Domestic Economy"—written by a doctor, and one who has made the matter a life-study. We offer it for only 50 cts., although the regular price of the book is \$1.00. If wanted by mail, send 8 cts. more for postage. Make your wife a present of one of these books, and it will enable her during the coming year to save many times its cost. It is a book that will be read clear through by almost everybody who gets hold of it; and you will be surprised on almost every page because you never thought of such simple, easy, short cuts for doing all sorts of things around the home.

GOOD BOOKS FOR A VERY LITTLE MONEY. []

[] We find we have in stock several hundred copies of two of the five-cent Sunday-school books that we have sold so extensively in years past. By some means these got dropped from our price list, and have not been advertised for some time. One of the books is called "Silver Keys." It is an excellent story with good wholesome morals. When first brought out the book sold for \$1.00. We now offer it for 5 cts., postpaid, until the stock is exhausted. The other one, Bunyan's Pilgrim's Progress, is very fully illustrated, and ought to be worth many times the insignificant cost (5 cts.) in any family. Many of our older readers have these books; but we think there are children now in almost every household who will be greatly benefited as well as interested in getting one of them for a Christmas present. Send right off now and we will try hard to mail it to you in ample time to be tucked in a little stocking.

HEALTH FOODS.

In our last issue I suggested that zwieback came the nearest to pure beef of any of the pure health foods I had tried. I find, however, that wheat-germ grits answer about as well when thoroughly cooked. Another recommendation, it costs only 5 cts. per lb., or 10 cts. for a 2-lb. package. Now, many of the friends have found it expensive to get these health foods, either by mail or express, and very few of them care to buy enough to order by freight, unless, indeed, it is to go along with other goods. There is already in the market an article recommended by our Dr. Lewis, and which seems to agree with me as well as the zwieback or any thing else; and that is Pettijohn's American breakfast food. You want to get the packages labeled "Pettijohn's Best." A 2-lb. package costs only 12 cts. at retail. One thing to recommend this article is, that it is already in the general market; and I believe it is kept on sale by grocers pretty generally everywhere. If you don't find it at your home grocery, when you are ordering other goods of us you can include it at

the above price. You can doubtless get wholesale prices by addressing the Eli Pettijohn Cereal Co., Minneapolis, Minn.

CELERY-PLANTS FOR THE NORTHERN FRIENDS.

We have some very nice plants now, ready to take up, of White Plume, Self-blanching, Golden Heart, and Giant Pascal. Good and strong plants, put out now in Florida and other southern localities, make nice celery, which will be ready just the time when they bring the most money in northern cities. Last winter Mr. Andrew Fooshe, of Titusville, Fla., sent five boxes of celery to Philadelphia, which brought \$12.00. See p. 229, last year. Prices of plants, 5 cts. for 10; 40 cts. per 100. If wanted by mail, add 5 cts. for 10 or 25 cts. for 100, for postage.

THAT 86-LB. COLORADO POTATO.

Quite a good many people have been undecided as to whether the above was a fake or a reality. The engraving appeared in the *Scientific American* a few weeks ago, given as a fact. Everybody acquainted with potato-growing should recognize the impossibility of the whole thing, notwithstanding the photo. We investigated, and received a pleasant letter from J. B. Swan, of Loveland, Col., explaining that it was a trick in photography. He did it only as a joke, to call attention to the advertisement of his seed potatoes. He said the *Scientific American* gave the picture on its own responsibility; in its issue the week after, they showed up the hoax; but the admission was not nearly as prominent as the first notice with its startling picture.

A PREMIUM WORTH \$1.50, AND GLEANINGS ONE YEAR, WORTH \$1.00, BOTH TOGETHER FOR ONLY \$1.00 IN MONEY.

The conditions of the above great offer are, briefly, these: To any person who is already a subscriber to GLEANINGS who will send it one year to some locality or some family that has not been taking it; or, in other words, any one who sends us a *new name*, together with \$1.00, can have, postpaid, 1 lb. of Maule's new Thoroughbred potato. This potato is not offered for sale anywhere to my knowledge, for less than \$1.50 per lb. We do this in order to get our journal introduced where it has never been taken before; and we are enabled to do it from the fact that we have purchased (at large expense) from Wm. Henry Maule ten barrels of this wonderful new early potato. For particulars in regard to the potato, see our Potato Circular, which we will mail to you on application. If you do not want to take the trouble to get a new name for GLEANINGS, make some friend or relative a present of it for one year, and send us the dollar. We will mail the potatoes right along as fast as the names are received—or, at least, until we have some evidence that there is danger of freezing in the mails. So far we have not lost a single pound. Mail matter is now so carefully cared for that there is very little chance of freezing unless you let them freeze while they are being brought home from the postoffice. We think the above makes the matter so plain that there can be no further mistakes or misunderstandings. The new potato is sent as a premium to any present subscriber for getting us a new name, and sending us the \$1.00. Please notice, we do not offer the potatoes for sale at any price. We expect to plant all that is left, ourselves. Those who have hot-beds and greenhouses can probably make no better use of their space under glass than to start these new potatoes now. We have some growing nicely that are six or eight inches high, in our greenhouse across the road from where I am writing. There is no easier plant to grow under glass, in the world, than the potato, providing you keep the frost from biting the foliage; and even if the tops are nipped it sets them back only a little, for they will start right up again. While they are worth \$1.50 per lb., you can make money by growing them in flower pots or boxes, in the window. And here is work for the women-folks as well as for the men. The potato is a very handsome window-plant, and just now there is money in it. See?

GLEANINGS comes regularly. I know I should miss it very much if it were not on time. Long may the Home of the Honey-bee prosper. Keep on; don't stop the hive question. J. H. GOE.
Mossy Rock, Wash.

Kind Words From Our Customers.

Potatoes received. Many thanks. Long live A. I. Root, son, and son-in law. E. B. RIFE.
 Circleville, O., Nov. 15.

GLEANINGS has saved us many times its price. We should not know how to get along without it. The honey crop is exceedingly poor in the country. The fires ran over large tracts of our neighborhood last year. Fireweed followed this year, and that was all that helped us out. MRS. S. WILBUR FREY.
 Plumville, Mich.

I still "think the world" of GLEANINGS. Long may it and its editor live and sow good seeds. We, your Christian readers, are bound by stronger than ordinary bonds to you. Long live the "admirable society." It does good to belong to it, even if only to admire others for their commendable qualities. A. MORTAZ.
 Utica, Ill., Oct. 17.

THAT CRANE SMOKER, AND WHAT IT WILL DO.

I received the Crane smoker there has been so much talk about, and I must say it is the best I ever saw. We need no better; for with it we can smoke every bee clear out of the hive, then smoke them in again. I know this can be done, for I have done it. Cumminsville, Neb. JAS. PRATT.

AN EXCELLENT SERMON CONDENSED INTO A FEW SHORT WORDS.

Dear Brother Root:—We heard such a good sermon last Sunday that I am constrained to pass it on, where it will do more good—I. COR. 10:31: "Whatsoever ye do, do all to the glory of God." The Christian motive of life, man's chief end, is to glorify God, since we are not our own, but we have been bought with a price. We belong to God, and all that we have comes from him—our time, money, health, opportunities, and all that we have, are lent to us from the Lord to be used for him and for his honor and his glory. But then we must not let this service to him be a tax or an unpleasant duty. We must not be satisfied with giving to him one-seventh of our time nor one-tenth of our property, but dedicate, consecrate the whole to him; and if we have the love to him that we owe, giving the whole to him will be a delight, just as Jacob served seven years for Rachel, and it "seemed but a few days;" and then since God is our Father, and such a bountiful giver, we will rejoice in his service, since we are assured that all things work together for good to them that love him; therefore we will account it always a pleasure to "rejoice in the Lord." Rejoice because we are the sons of such a great, glorious, almighty king.

Now, brother Root, I do not wish to interfere with a single one of your Home Talks. I send you this as only so much matter which you can weave in or use as you see best; for I take more pleasure in reading Myself and Neighbors than all the rest.

Hammononton, N. J., Nov. 13. A. H. VANDOREN.

This Steel Fence Post is superior to any other on the market. It is driven into the ground with a wooden maul, and will neither Rot, Rust, nor Burn. It is adapted to plain, barb, or any of the patent fences. Ten posts can be driven in the time it takes to dig one hole for wooden post. For Catalogue and prices, address

INTERNATIONAL STEEL POST CO.,
 710 Chestnut Street, St. Louis, Mo.

Please mention this paper.

Something New!

A Comb-Honey Hive

containing 10 closed-end standing brood-frames, 15½x6½ net comb space, and 32 5-inch Prize sections 3½x5 in.; adapted to furnish standard Langstroth hives as bodies or supers with full space for top packing for safe wintering and promoting work in supers; forming solid double walls with intervening air-spaces tightly covered, and perfect bee-escapes, with all free of cost; manufactured by The A. I. Root Co., and now being exhibited by the inventor at the Atlanta, Ga., Exposition, in the Dade Co., Florida, division in the Agricultural building. One complete sample hive ready for bees, \$2.25; 10 complete in flat with nails, \$15.00.

For present, address

F. DANZENBAKER, City P. O., Atlanta, Ga.

(In responding to this advertisement mention GLEANINGS)

PURE HONEY

At 5½ and 7c per pound, in cans and kegs.

SUPPLIES

at bottom prices. Wax Wanted.

I. J. STRINGHAM, NEW YORK.

105 Park Place.

BEGINNERS.

Beginners should have a copy of the Amateur Bee-keeper, a 70-page book by Prof. J. W. Rouse. Price 25 cents; if sent by mail, 28c. The little book and the Progressive Bee-keeper (a live progressive 28-page monthly journal) one year, 65c. Address any first-class dealer, or
